About three years ago, Dr. J. P. Dullard was called to the Third Ward at midnight to attend Mrs. C.; found right "arm down." He worked with her until three in the morning, then the late Dr. F. N. Dick was called in to assist. At five o'clock in the morning the writer was called in, and within thirty minutes she was delivered of a dead child, full grown. Mother got along nicely; no trouble.

The following week Dr. J. P. Dullard was called to wait upon Mrs. M, in the Second Ward, and found left "arm down." The Doctor sent a hurry-up message for the writer. Anesthetic was administered, and in a short time an eight-months dead child was born.

By adopting the above-described course the back of the hand is at all times right, and we get the feet.

[Written for the MEDICAL BRIEF.]

Influenza and Intermittent Fever.

BY JOSEPH D. HARRIGAN, M. D.,
New York City.

In several articles written recently, after comparing the symptoms of influenza with those of cholera, typhus fever, and relapsing fever, I advanced the theory that these and other epidemic diseases of this class are based on one common set of symptoms as a foundation and framework.

Any one can verify for himself the truth of this theory by making similar comparisons.

Paralleling the so-called phenomena of the various epidemic diseases, one can not but be struck by the remarkable preponderance of purely influenzic symptoms throughout them all. In none of them, however, are the analogies more markedly prominent than in influenza and intermittent fever. In fact, the resemblance of these two diseases to each other is so pronounced that one feels perfectly safe in assuming that the causative factor of production in the one case will also be found to be essentially the same in the other.

So that if, as many believe, marsh gas, or carburetted hydrogen, is the cause of intermittent fever, we would be compelled to seek for some similar chemical as the cause of influenza. A comparison of the two diseases will, I feel sure, justify one in making this quest.

Taking up the various symptoms, according to Zuelzer on "Influenza," and Mertz on "Malarial Diseases," we find the following recorded observations:

The Onset—"In influenza the onset of the disease is generally sudden. * * * It is marked by a decided chill, or by malaise, lasting several hours, with slight chills, alternating with heat. Only in rare cases are we apt to have malaise for several days, and an established cold beforehand."

In intermittent fever, according to Mertz:

"* * * The period of incubation may be of variable length. I have repeatedly satisfied myself that the disease may appear immediately after the reception of the injurious influence. For this purpose I have sat down beside marshy ditches, which were in process of drying, selecting those in particular that were distinguished by their putrid exhalations. As soon as within half an hour I would experience a slight disturbance of vision, ringing in the ears, dizziness, a feeling of roughness and burning in the throat, nausea, choking sensations, and chilliness, and a few hours later an attack of fever, which was generally slight.

Salisbury states that when, in the pursuit of his investigations, he passed over a stretch of marshy moorland, * * * he used to experience a peculiar sensation of heat and dryness in the fauces and throat, extending down to the bronchi, and accompanied by a constant impulse to hawk or clear his throat."

Professor Flint says, concerning intermittent fever:

"In the majority of cases the attack is sudden. In a certain proportion of cases, however, there are premonitions for a variable period."

Speaking of the variations in mode of onset of intermittent fever, Mertz says:

"An attack of simple, benign, intermittent fever is not seldom preceded, in persons inhabiting a malarious region, by a prodromal stage, lasting from six to eight days, or even longer, which, in itself, shows but little that is characteristic, and justifies no conclusions as to the disease which is to follow. The symptoms consist in general disturbances, such as occur also in other acute infectious diseases, and often suggest typhoid, rather than intermittent fever."

This statement would naturally lead us to inferentially assume that, in persons living in regions not malarious, the attack, in case the disease poison were conveyed thither, would, in all probability, be sudden.

It is to be particularly noted that Professor Hertz makes mention of these prodromal symptoms, in connection with simple, benign intermittent. What this article has to deal with, though, is not with this form of the disease, nor any one or other form exclusively. In comparing it with influenza, we must bring to bear a broad-minded consideration of the entire field of intermittent fever, no matter under what qualifying name, typical of its severity, its geographical localization, or

distribution, its so-called "complications," etc., it may pose. Whether it be "benign" or "pernicious," "fever and ague" or "shakes," "icteric" or "neuralgic," "Panama" or "Chagres," "masked" or otherwise, the consensus of opinion is in accord in declaring that the essential etiological factor pertaining to its genesis is to be found in some emanation or emanations arising from the swamp lands, or from freshly-upturned moist earth.

As it is a well-known fact that intermittent fever, in the neighborhood of salt marshes, is more pernicious than that belonging to other swampy localities, it can be safely predicted that the differences in severity depend principally upon the environments, which, scientifically considered, would mean the chemicals going to make up earth, air and water. The symptomatic phenomena must, consequently, suffer wide variations, and, in fact, the disease be almost impossible of differentiation from other diseases of the same class. On the other hand, influenza can run the gamut of symptoms of these diseases in exactly similar manner, and is, in my humble opinion, entitled to be called intermittent just as logically as any of those diseases bearing that title.

Mucous and Serous Membranes.—In influenza, Zuelzer says:

"Almost invariably a considerable portion of the mucous membrane, especially that of the respiratory organs, is affected, and this is the characteristic feature of the disease.

"The symptoms are essentially of a catarrhal nature. We find most frequently marked cold in the head, with considerable discharge from the nose, and, sometimes, epistaxis; redness of the conjunctiva, with abundant lachrymation; catarrh of the mucous membrane of the throat, larynx and bronchi; also, sore throat, difficulty of swallowing, hoarseness, tendency to cough, and a burning or tickling sensation in the throat. The mucous membrane of the cavities of the nose, mouth and pharynx is generally found reddened, and the tonsils swollen."

Comparing these symptoms with what we find in intermittent fever, one can not but be struck by the analogy existing between them. Mertz says:

"Masked fevers may, furthermore, manifest themselves in the form of intermittent hyperemia, hemorrhage, edema, and inflammatory disturbances of nutrition. Among the latter are typical coryza, bronchial catarrh, swelling of the tonsils, * * * hemorrhages from the nose, the lungs, * * * furthermore, typical iritis and ophthalmia."

Farther on he says:

"Aside from the cases in which a pre-existing bronchitis, pneumonia, or pleurisy, is aggravated in its symptoms, or modified in its course, by an intercurrent malarial fever, it also appears possible for such a fever to localize itself in the bronchial tubes, the lungs, or the pleura, and there call forth manifestations in no degree inferior to those of the genuine diseases of these organs. We may thus meet with a sudden outbreak of hyperemia of the bronchi, in which the patient * * * suffers from the most intense anxiety and constriction of the chest.

"More interesting than these, however, are the cases of *intermittens perniciosa pneumonica and pleuritica.*

"During the chill and the hot stage, the patients are seized with dyspnea; they cough much, without expectoration, and complain of the most violent pain in the breast * * * dullness on percussion and increased vocal fremitus, are manifest; while auscultation reveals, at first, crepitant rhonchi, then bronchial breathing and bronchophony. During the sweating stage a decided remission of the fever takes place, as well as an abatement of the symptoms, subjective and objective, which may almost entirely disappear during the intermission that follows. In case of a renewed paroxysm, however, of the quotidian, or tertian type, these symptoms will recur. The infiltration will now increase somewhat in extent, and remain stationary during the intermissions."

Returning, now, to influenza, we find, according to Zuelzer:

"At the very beginning there sets in a very tormenting, convulsive, dry cough, which becomes paroxysmal, especially in the evening and at night, not infrequently leads to vomiting, and often leaves behind it pains in the respiratory muscles. The sputa are very scanty and muco-serous. In less frequent cases they become more

abundant towards the end of the disease. * * * Auscultation frequently reveals sonorous, or in places, crepitant, râles, as in the case of non-epidemic laryngo-bronchitis; still, there also occur cases in which all the auscultatory phenomena are very insignificant, or absolutely wanting. According to Graves' view, they sometimes occur with intermittent, or rhythmically returning, remissions * * * With many patients these phenomena go on to great oppression, marked dyspnea, pain in the precordia, etc. Pleuritic stitches, too, and pain under the sternum are observed without any appreciable physical changes. In certain epidemics these suffocative states are rather frequent."

In intermittent fever it is stated also by Mertz:

"* * * In persons predisposed thereto, especially those who suffer from frequent congestions of the lungs, or give evidences of scurvy, the most violent pulmonary hemorrhages may ensue * * *"

As compared with this in influenza, it is stated by Zuelzer:

"In phthisical, and also in full-blooded persons, they (the sputa) sometimes contain an admixture of blood."

That the bronchitic inflammations in intermittent fever are by no means rare is shown by the statement of Mertz, further on, in his analysis of the individual symptoms, that:

"* * * simple intermittent fever is sometimes accompanied by attacks (either sporadic or in some degree epidemic) of bronchitis, with dry or moist rhonchi, cough and dyspnea, which arise during the cold stage, diminish gradually during the stage of sweating, and disappear entirely during the intermission. They undoubtedly depend upon hyperemia of the lungs, with swelling and excessive secretion from the bronchial mucous membrane."

The Gastric and Intestinal Mucous Membranes.—In influenza Zuelzer states:

"The mucous membrane of the digestive organs is, likewise, affected in many cases, although generally not to so high a degree. Loss of appetite, increased thirst, a coated tongue, a bad, pasty taste, sensitiveness of the epigastrium, and, not infrequently, colicky pains and diarrhea, or nausea and vomiting, accompany the disease. In other cases there is persistent constipation."

In intermittent fever, Mertz says:

"The patient feels a sensation of fullness and tension in the epigastrium, is obliged to draw deep inspirations, complains of nausea, and often actually vomits. The taste is stale, bitter, often metallic, rarely acid. * * * At the same time there is loss of appetite, repugnance to animal food, a foul breath, constipation or diarrhea, and considerable thirst." Professor Mertz treats, at some length, of the choleraic form of intermittent fever.

Inasmuch as the symptoms in this form, "which is of quite frequent occurrence," are identical with those of so-called Asiatic or, as the author quoted naively terms it, "real cholera," it would seem self-evident that they are essentially, unequivocally, and without a particle of doubt, one and the same thing.

What better description of cholera can be drawn than the following in this form of intermittent fever?

"* * * Intermittent fever may assume a pernicious character, by virtue of other alarming symptoms. Under this head comes the choleraic form of the malady, which is of quite frequent occurrence, and in which burning thirst, severe vomiting of yellowish matter, and greenish, diarrheal passages appear during the continuance of the fever; the passages from the bowels becoming more and more watery, and sometimes resembling bloody water. Subsequently, just as in real cholera, general oppression and the most tormenting precordial distress are felt; cramps in the calves of the legs, coldness, and a livid appearance of the skin follow, with a small, hardly perceptible pulse, sunken eyes, and a true Hippocratic countenance. Convulsions are not infrequent. Death supervenes, with all evidence of asphyxia. Another variety, which bears a striking resemblance to the foregoing, is that known as *algid intermittent*, characterized by a coldness of the body like that of marble, while the temperature in the mouth is from 86° to 88° F., and that in the axilla, 84° F.

"The attack begins with the usual chill, which is not of abnormal severity or duration. It is not until during or after the hot stage that the patient grows cold,

while at the same time he complains of burning heat within, and of thirst; the skin turns pale and livid, is stiff and covered with a cold sweat, the pupils are dilated, the eyes expressionless, the lips blanched and dry, the tongue smooth, pale and soft, and the region of the stomach sensitive. Mucobilious vomiting is liable to occur, with occasional greenish-yellow stools, though both of these may be absent, and are of subordinate importance. The urine is scanty, high colored, turbid, of high specific gravity, and free from albumen. * * *" Upon this freedom from albuminuria depends, to a very great extent, according to some authorities, the diagnosis of algid intermittent from cholera. And yet, illogically enough, that special form of intermittent, "called by the French, from its prominent symptoms of a billious condition, and bloody urine, *fèvre bilieuse hématurique*," is recognized as a true intermittent!

Why albuminuria should exclude the one and hematuria not exclude the other is, I must confess, a little beyond my comprehension. However, it is to be taken simply as only one of the many inconsistencies in the history of epidemic disease, evidencing a rather unsystematic method underlying their investigations.

Continuing the description of the algid form, Mertz says:

This form of pernicious malarial fever is usually confined to warm countries, and is, as a rule, preceded by some paroxysms of simple intermittent. Even in these simple paroxysms, however, according to Rigler, there is an unusual prostration, reaction is imperfect, and the coldness of the face and extremities during the paroxysm is striking. It is said that these attacks may terminate in spontaneous recovery; usually, however, death takes place, either in the first attack, or, if they are repeated, in the second to the fourth. Recovery follows through a reaction, like that from cholera; it is not unusual, either, to find a typhoid condition supervene, like that after cholera.

Now, in comparing this choleraic form of intermittent fever with influenza, it will be found, on close investigation, that the symptoms in both are almost identical, not, it may be admitted, in degree of severity, but from an anatomical and pathological standpoint.

As I pointed out in a previous article, the chronological order of symptomatic happenings is simply transposed, this transposition being readily understood when viewed in the light of chemical and electro-chemical laws, to which the human body is subject.

If the patients withstand the first onslaught of the profuse diarrhea, we find the following:

"Congestions frequently occur in the head. The face, under these circumstances, is reddened, but unequally, so that it has a spotted appearance. The eyes are congested and lachrymose. Most patients complain of a fullness and heaviness in the head, or of a dull headache, either general in character or seated in the forehead or occiput. Roaring in the ears is frequent. Notwithstanding a certain tendency to somnolence, the most enfeebled patients are usually sleepless. * * * In a still later stage the so-called cholera eruption shows itself. This eruption is, at one time, of erythematous, at another of urticarial character, or it may show a roseola-like appearance."

This sequence of symptoms is simply a reversal of the order of procedure that maintains in influenza, that is, to a certain extent. Thus, after the occurrence of the coryza, the bronchial symptoms, the ordinary gastric and nervous symptoms, etc., we find it stated by Zuelzer:

"In 'uncomplicated' cases the disease generally ends in recovery * * * it generally terminates critically, either with sweat or epistaxis, abundant diarrheal discharges, or increased secretion of urine."

Even the eruptive features of cholera are duplicated in influenza. Thus:

"The statements of the earlier observers about the complications of influenza with exanthemata, such as miliaria, roseola, urticaria, petechia, scarlatinal spots, erysipelas, etc., seem to refer, as Biermer assumes, chiefly to miliaria and urticaria."

We find all these duplicated in intermittent fever, so that what is said concerning the identity of nine-tenths of the symptoms of cholera with influenza, can be reiterated most emphatically with re-

gard to influenza, as compared with intermittent.

The vast majority of the symptoms in both of these diseases; in fact, not alone in these, but, likewise, in cholera, relapsing fever, typhus, and a host of others of this class, exactly coincide, showing conclusively that there is a common, basic ground-work upon which they are all constructed. Consequently, if such be the case, it is logical to assert that the causative factor of these common basic phenomena must be the same in all these manifestations of epidemic disease.

Being obliged, by lack of space, to curtail this necessarily brief comparison of influenza and intermittent fever, I shall leave to a future paper the consideration of still more striking analogies existing between them.

Rectal Diseases—the Bete Noire of the Physician.

BY HOWELL B. GWIN, M. D.,

Nashville, Tenn.

II.

My first article dealt, in general and briefly, with hemorrhoids, which I believe to be by far the most common of rectal diseases. My next article will be largely devoted to the treatment of hemorrhoids. Attention is now called to several leading forms of rectal diseases.

By way of parenthesis, we must clearly apprehend the meaning of the word "tumor." Literally it is a swelling, and is employed in the description of various rectal affections. Tumors are of two kinds, benign and malignant; the benign are usually curable, the malignant usually incurable. Consider, first:

Fistulæ.—These appear to be due to abscesses, deep or superficial, and, after rupture, there is burrowing into and through neighboring tissues in single or combined lines or sinuses. A small minority of fistulæ are nonprogressive, but the overwhelming majority are progressive, becoming more and more fraught with evil and danger. Abscesses arise in several localities: (*a*) Far up in the ischio-rectal fossa; (*b*) below this, in the superior pelvi-rectal space, and (*c*) on the margin of the anal orifice. Abscesses are more frequent in the loose connective tissue, and are caused by inflammation, bruises, wounds, etc. A fistula may not always open into the rectum. Sometimes a stricture of the rectum will cause an abscess issuing in a fistula. Both the stricture and fistula must be treated. To treat one without the other is unscientific and nugatory. A charlatan will apply a cautery, or inject strong acids, and pronounce his patient cured, but the last state will be worse than the first. A fistula will lengthen its fearful and fatal burrowing in several directions, and it is the grossest malpractice to close prematurely its openings, thus driving within the poison through several sinuses. In many cases, in order to effect a complete and healthful drainage, the common-sense treatment is surgical; the fistula must, therefore, be kept open, even if frequent probing be employed. The cleansing and healing of the sinus is the problem of the practitioner, who should never excoriate the sensitive membranes by the use of the cautery, caustics, escharotics, acids, etc.—this would be to undo the preparatory work of the surgeon. The necessity is the rebuilding of the tissues without the slightest injury, and, from the first, the treatment should be non-irritating, analgesic, antiseptic, and absorbent; in short, reconstructive.

I do not lay much stress on the so-called varieties of fistulæ, such as complete, blind external, blind internal, etc., for these are but stages in their progress, which do not materially affect the treatment.

Fissure.—This has sometimes been called an "irritable ulcer of the rectum," but this is not a clear-cut definition. An ulcer or tumor may be a concomitant, but the fissure is distinctive. As its name imports, it is a crack. Primarily, and in most cases, fissure of the anus is a lesion of the mucous membrane only, though the submucous and even muscular tissues may be involved in old cases. The lower end of the fissure is usually just within the margin of the external sphincter, though sometimes it is found higher up, and may exist on either or both sides of the bowel.

In appearance it resembles the crack in a lip resulting from what we call chapping; not healing readily, it soon passes into an ulcer. It may be an eighth of an inch wide and a quarter of an inch or more in length. To repeat, an abscess or ulcer producing a small tract or sinus will exhibit characteristic symptoms of a fissure.

On its inception, there is not much severe pain; its advancing steps are marked by smarting, stinging, aching, throbbing, burning or lancinating sensations, becoming, finally, almost intolerable. Generally this pain is not much felt in the act of defecation, but within half an hour or more it sets up, becoming sharp and cutting, then for a while may subside—a condition guiding one in the diagnosis of fissure. A skillful surgeon will tell you that a typical fissure is the most painful of all diseases he is called upon to treat, but he will also tell you that it is more easily cured than some other rectal diseases.

Some insist upon an operation. I do not affirm that an operation is contra-indicated in extreme cases, but I do insist that this disease is curable without the knife; indeed, I can say that the majority of cases coming to me have been cured without the knife, and without the cautery, and strong acid fluids and salves. This was not my experience for many years, for I blindly followed methods of treatment that have descended traditionally *ex authoritate*.

Here let me say that I value the experience of men more than their theory. It is easy to twist facts to confirm a preconceived theory; it is scientific to gather all facts and thread them with a co-ordinating principle, and this, indeed, is the Baconian method which has almost created the science of modern times. I urge more independence of thought and action to induce a physician to think for himself, which is always a prophecy of power. Let him not lose his head or sacrifice any fact established by science. Let him, also, realize that science has never finished its work, is always progressive, and that the honest, independent student is the chief factor in all discoveries and inventions. Such a man is a benefactor and the hero of to-morrow, whatever may be the record against him to-day. My readers have discovered my aversion to the knife. I believe that many persons have had their health wrecked, while others have lost their lives by the reckless use of the knife, illustrated, for example, in ovariotomy, as well as many other diseases.

It is not my purpose to give well-known details, though advising that these be studied independently by the practitioner, who, shunning the bondage of traditionalism, should gather all facts for his diagnosis and therapeutics. In concluding this article I make brief reference to other, not all, rectal diseases.

Polypi sometimes make their appearance in the rectum, as in the nose, vagina and uterus. They are not common; they sometimes spring from a false treatment of hemorrhoids by acid injections. A polyp has a pedicle on the mucous membrane, though this is not pathognomonic; it is usually small, appearing sometimes soft, sometimes hard, occasionally attended with bleeding. Its irritation may cause ulceration. It is sometimes complicated with fissure, fistula, or hemorrhoids, and when these are treated the polypi should be carefully observed and removed by the simplest method, which is to ligate them, and sometimes to cut them off near their connection. The after-treatment of the mucous and other membranes must be judicious and complete, in order to avoid, if possible, the recurrence of the polypus. Again, it will be seen that I carefully avoid scarifying living tissue.

Ulcers.—These are of so many varieties, and so often connected with other rectal diseases, I need not detail their character and effect. As a rule all purulent matter should be discharged, and on account of location and probable complications, the tissues should be purified and healed by remedies that leave no injury. Just here I would parenthetically add, that cancers are not now under consideration, nor any disease which may be transferred to any part of the body by metastasis.

Pruritus ani is sometimes a concomitant of other diseases, but, strictly speaking, it is an independent disease, which may be constitutional or local. It appears to be neurotic, is attended with little pain, but intolerable itching, and is most difficult to manage and to cure. As terminal

nerves are the most important factor in this trouble, they, with all reflexes to other organs, must be carefully looked after. The cuticle, converted into scarf-tissue, must be destroyed to obtain a cure, and while the rectal specialist is called upon to treat this disease, he should be thoroughly acquainted with dermatology. It is his province to discover rectal complications and control them, but in treating a typical case of pruritus ani we must necessarily use the best remedies of the dermatologist, and hence a constitutional and local treatment, co-operating, will bring the best result. The habits of the patient, in this and all rectal diseases, must be looked after, proper hygienic measures enforced, and a proper diet used, while, of course, we should avoid the use of intoxicants and stimulants; warning against alcohol, tobacco, excessive sexual indulgence, and other dissipations, as well as against morbid mental states arising from the perplexities of business or otherwise.

Prolapsus Ani.—This is the protrusion of the mucous membrane of the bowel, occurring with children, with women who have borne many children, and with men as well. In the adult it may be due to several causes, such as constipation, diarrhea, enlarged prostate in the male, polypus, piles, etc., and sometimes to a strumus or syphilitic cause. The usual treatment is palliative and surgical. Here, again, I will say that while in extreme cases I would not obstinately reject surgical treatment, I do honestly believe that the persistent use of a palliative or, rather, reconstructive remedy, will yield the best results. In treating prolapsus it is necessary to see that the nourishment is proper, and the blood normal, and that the morbid condition of the stomach, bowels, liver, bladder, etc., is removed. In some cases tonics and aperients will be necessary. But, the supreme aim of the physician should be to replace and reattach the mucous membrane to the internal muscular membrane. I have been greatly gratified by the cures permanently effected by my non-use of the knife or of escharotics, and by the steady use of reconstructive remedies. I do not deem it necessary to speak specifically of cancer, neuralgia and stricture of the rectum.

Without hesitation I have presented fundamental facts and principles expounded by accepted authorities, for there is no progress except from the known to the unknown, yet truly there is no *ultima thule* in any science realm. Sight, insight, and foresight, profound and unremitting, are necessary to progress. Woe to the man who is paralyzed by an obstacle! He is the antitype of the ass, of whom Horace speaks, that "stood by the river's edge waiting for the water to pass before he would cross." I claim for the medical profession a larger personal liberty, a wider vision, a more fraternal spirit, more independent conviction and research, and a more progressive application of facts and principles, and less of organized espionage and syndicated policies.

After the manner of my last article, I desire to ask a few questions. Brother Physician, have the old crystallized methods of treating rectal diseases given you and your patients satisfaction? Have you not often asked yourself whether there does not exist in the realm of the unknown remedial agents to overcome the obstacles that baffled you? or whether among agents already known there may not be new curative combinations? Are you thinking and searching for a remedy and are you willing to accept without distrust or prejudice new, rational remedies? Has the time arrived when you are willing to break the fetters of a narrow and wornout code or system which virtually bids you to sneeze when others take snuff? No answers to these questions are asked for—you are simply urged to think!

In my next and closing article I will deal specially with the treatment of rectal diseases.

[Written for the MEDICAL BRIEF.]

To the Medical Profession.

BY ELLA A. JENNINGS, M. D.,
Brooklyn, N. Y.

Thinking my case may interest medical men and women, I hereby submit a synopsis of it:

For twenty-eight years I was actively engaged in the practice of medicine in New York City. In the spring of 1904 I met with a serious financial loss, greatly

aggravated by the circumstances attending it. For some months I was overwhelmed by grief, loss of sleep, loss of appetite and interruption of the bodily functions.

On January 15, 1905, I had an attack of heart failure while ascending the elevated railroad stairs; was assisted home, and called Dr. Simpson, of One Hundred and Fifteenth street, a specialist in heart troubles and the nervous system. He came four times in four hours, and told me "there was no hope for me; that I was liable to die any moment with angina pectoris; that medical skill was unavailing."

The agony of the spasms was indescribable. For over sixteen hours I pumped the heart by pressure of the hands. The sensation was a smothering or drowning in your own blood. At 6 a. m. I had the New York Medical College and Hospital for Women telephoned for accommodation, and requested them to send a physician for me at once. Upon my arrival I said: "I want the best woman physician you have, and she must understand the right remedy, and if she is not here in half an hour, I'm a dead woman." Was undressed, put to bed, and immediately relapsed into unconsciousness, and slept sixty-two hours. Remained in the hospital for three weeks, and went home.

In April had another shock to my nerves and heart; the spasms recurred, and from 2 A. M. until 11 A. M. they were almost constant. Cardiac dyspnea set in, and the difficulty of breathing greatly augmented my suffering. It was agonizing. During the year I consulted some twenty eminent physicians of both schools; few of them offered me the least hope; some said: "I was liable to die any moment; the climbing of one flight of stairs might stop the heart beating."

One physician, a specialist of repute, told me "it was a very bad case of nervous angina, and that three years' rest would restore me to health." Others were certain it was organic, and hopeless.

I refused to accept their verdict. A heart that had served me faithfully for over half a century could not so suddenly go wrong. I had lived so careful a life; never taking any stimulants; not even coffee, and tea only in small quantities and occasionally, and always observed sanitary measures, baths, diet, physical culture, etc.

One doctor advised twelve-year-old rye whisky in small doses. Found benefit from the Nauheim baths, also Emile Batchelet's magnetic generators. Went to Ocean Grove, N. J., and found the air, quiet and restfulness of the place a great benefit.

In October, 1906, took an apartment and resumed practice; felt pretty well; mind hopeful; courage and strength returning. October 12, 1906, a sister's death, under very sad circumstances (self-induced by morphine through melancholia), gave me a shock that brought a return of the heart spasms and dyspnea and suspended the functions of some of the organs. The liver ceased to contribute the necessary bile, and the stools were the color of chalk; the stomach refused to digest the food; it passed through the alimentary canal, undigested, fermented and foamy, like yeast. The pulse seldom below one hundred and forty; sleep not more than one or two hours in the twenty-four. Dyspnea prevented a recumbent position, so distressing as to make life a perpetual burden, and death a desired release. Mental depression and sadness had replaced an unusually cheerful and happy nature. Kidneys secreted very little; urine of a dark color, and where I had usually passed three pints in the twenty-four hours, I seldom voided more than six to twelve ounces in the twenty-four hours, sometimes even less. Face had an expression of anguish. In January, 1907, had a severe congestive chill, and dropsy set in; feet and legs were swollen to three times their normal size. Called the same physician, who had probably saved my life at the hospital; she prescribed kali carb., and the dyspnea was greatly lessened for a time. She urged my going to California at once. Kidney, stomach and liver troubles continued. For the first time in nearly three years of my illness I began to lose hope; felt that hydrotherapy might help me. Called up Dr. Simon Baruch, and learned they did not receive patients only for daily treatments. I wanted baths, diet and nursing.

On March 5th I went to Miller's Hotel and bath-house; spent five days, and grew

rapidly worse; the dropsy ascending and increasing steadily. Dr. Miller, believing my case as likely to terminate fatally any day, requested my sister to remove me. I then made application to another sanitarium, where they gave the water treatment; their physician reported my case adversely as "too far gone to recover." While waiting for their decision, I recalled Dr. Shepard's sanitarium, in Brooklyn, and had Dr. Miller's secretary phone to see if I could have a room there. There were no formalities as to liability to die, no physician's examinations to see if I were a safe risk, but the reply came: "Dr. Jennings can come right over; we have a room." Thank God; death was not a crime in the doctor's sanitarium. Dr. Miller sent his secretary with me, thinking I might die en route.

Dr. Shepard first introduced the Turkish bath in this country some forty-four years ago; is eighty-two years old; has absolute faith in his methods, which are baths and fasting, sweating and starving out the disease. He is not afraid of moribund cases, and has snatched thousands from the grave, and worse still, the hopeless despair of disease. He looked me over, took my pulse, one hundred and twenty-five; looked at my tongue, and said quite cheerfully: "You are pretty sick, Dr. Jennings, but I guess we can pull you through if you are willing to take the medicine." I replied: "I can not take strong drugs; never have, and can not even to save my life." He put me on a strict water fast, with a little lemon juice (but no sugar), for six days, a daily Turkish bath and a light body massage. This was my regimen for the first six days; the next four days, three oranges, and water, if thirsty, and a subsequent four days, boiled onions once a day to eliminate the impurities of the system. Was very hungry on the thirteenth and fourteenth days, and so ravenous on the fifteenth day I insisted on some food. The doctor had designed to keep me thirty days without eating, or until my pulse had decreased to normal. The doctor is rather heroic along these lines, and believes that only by abstinence and rest that a stomach regains power to digest and make good blood from good food. Before going to Dr. Shepard's I had not lain down in nearly three months, except for an hour or two; had to rest in a Morris chair. The cardiac dyspnea was constant; my feet and ankles swollen to three times their natural size; my mental condition one of hopeless despair and longing for death. Had not slept upon my right side or back in three years; no appetite; unable to digest even hot or malted milk. After the first bath the dyspnea was greatly relieved, I could lie down; after second bath it had disappeared, and upon the fourth day the dropsy had vanished entirely. After fifteen days of abstinence, I had a chop and some educator crackers, and never did food taste better.

I have been here for six weeks; sleep like a child; am getting strong; can walk two miles without fatigue; feel comfortable and satisfied with one light meal a day at 1 P. M., consisting of soft boiled egg or a chop, with spinach and celery, or water-cress, onion, lettuce and brown bread and butter. Have learned much along the dietetic lines, and regard my stay here as the most valuable experience of my life. Doctor says that I ought to give myself at least six months' rest to get well, but women physicians have no tobacco, beer, whisky or other bad habits to overcome, and so rebound more quickly. My pulse is down to seventy for the first time in three years, and I feel really well and strong, but have agreed to keep the brakes on so as to have a relapse. The baths and massage are delightful, refreshing, and the twenty-two pounds I have lost are a gain. Lost eighteen pounds the first two weeks; some of it being the dropsical effusion. Passed four to six quarts of urine daily for eight days. Mental depression gone; cheerful, happy, hopeful, and feel that life is once more a joyous thing. Am perfectly willing to confine myself to one meal per day, if health can thereby be secured. The pleasures of the palate are as nothing compared with pain and suffering of unwise or overeating. If my case aids any of my fellow physicians, I am amply repaid.

I feel assured that many of you will rejoice that so simple and effective a cure can be made life-saving in so formidable a disease as angina pectoris and cardiac asthma and dropsy.

Diphtheria: Is the Prevailing Antitoxin Treatment Only Another Medical Delusion?

BY CHARLES E. PAGE, M. D.,
Boston, Mass.

Demonstration fails to change established beliefs.—HERBERT SPENCER.

Upon *a priori* grounds, every sensible person would be likely to say, off hand, that a diphtheritic patient's blood is sufficiently charged with filth without injecting any foreign substance, and, least of all, the serum of the blood of a poisoned horse. The attempt will herein be made to produce facts and figures such as will tend to induce all intelligent men, in or out of the medical profession, to oppose the employment of antitoxin on *a posteriori* ground that it is a true toxin, instead of what its name would imply.

"You could have knocked me down with a feather," is an expression often heard, and the meaning of which we all understand—a sudden weakness arising from some emotion, as fear, surprise, etc., lowering the individual's power of resistance to force from without. It is the writer's belief, based on many years' observation in active practice, that fatalities are constantly occurring as the direct and natural effect of so-called medicinal doses of virulent poisons. To weak and exhausted patients the smallest dose of poison may prove as deadly as the heaviest amount administered to a healthy person for homicidal purpose. The stupid phrase, "heart failure," covers a multitude of sins against life and common sense.

"It was a brilliant operation, but the patient—died," and this result has often happened in cases in which no surgical treatment was called for, if only the physician in attendance had understood, and had been skilled in administering hygienic treatment, including, of course, hydrotherapy, with its almost endless devices for relieving internal, as well as external lesions. "Died cured," is a phrase descriptive of two cases treated by one of our leading hospital doctors, when he was beginning his career. They were cases of heart disease, and he cured both with digitalis. "The triumph seemed complete," he said, before the Harvard Medical School Association, "and so it was for weeks; but, mark the ultimate result. Mary, one morning, as she trod the doorway of the market-house, fell dead upon the threshold. The banker, some weeks later, stretching his arm across the desk that had been to him the pathway to riches and power, fell hushed and powerless into the eternal silence."

The recollections of the teachings listened to in his medical course, sends a cold chill along the writer's spine, particularly as he is aware that most of the other young bumpkins swallowed the whole business, "hook, line, bob and sinker," and have for a generation been "practicing" on the principle—for this is about what it amounts to—that what is bad for the healthy is good for the diseased; that known poisons, which tend to make a well man sick, or to kill him, tend to make him well when he is sick! It is this which fully accounts for the rise of the mental healer, the "scientist," the faith-cure, etc. If these do nothing to help the organism in its emergency—in its efforts to eliminate the disease-producing matters—they, at least, do not add to the already over-poisoned condition, and to that extent nature has a fair chance to restore "that just balance which we call health."

There are to-day more physicians who have practically abandoned the use of potent drugs than at any former time, but it is still true that the chief reliance of nine hundred and ninety-nine out of a thousand of all so-called regular physicians, is drugs, and especially alcohol in some form. And this in face of such evidence as may be found in the experience of one of the foremost physicians in the world, and his entire staff, in one of the chief hospitals in England. The late Sir B. W. Richardson, of the London Charity Hospital, stated that of late years very little medicine had been used, and not a drop of alcohol, in any form, had been given to patients at his hospital. Neither acute nor chronic diseases have been treated with alcohol in any measure, and the mortality has been less, disease for disease, than at any hospital in England.

If it can be truly said of alcohol, the one drug poison most extensively employed

by physicians of all schools, and in almost every form of disease, that it is always harmful, and tends to lessen the chances of any sick person to get well—and that is precisely what is meant by Dr. Richardson's experience and testimony—what further need be said in condemnation of all poisons in the treatment of sickness?

Antitoxin treatment for diphtheria! What can be said in praise of it? Dr. Carl Strueh, of Chicago, in "Criticism of the Antitoxin Treatment from a Different Standpoint" (*Journal of the American Medical Association*), and "Once More on Antitoxin," after a careful analysis of an immense array of statistics, shows very clearly two things, viz.: first, that the statistics are very misleading, since nowadays almost every kind of sore throat is assumed to be diphtheritic, and a rush is made for the antitoxin doctor, and, therefore, a vast number of simple cases, such as always recover, even with no treatment whatsoever, are set down to the credit of the serum treatment; and, second, that the virtues of the antitoxin method are altogether negative—that is, in taking the place of a worse treatment the patient is given a better chance to recover through the efforts of nature.

Dr. Strueh says, concerning injections made for prophylactic purposes, that "we must agree that it is not the rule that from one child being sick with diphtheria the majority of the family becomes infected. If we, therefore, apply antitoxin to every member of a family in which there is a case of diphtheria, we can wager ten to one, of course, that the result will be in favor of antitoxin. The followers of the antitoxin treatment declare that it is necessary, in order to get the best results, not to combine any drug treatment, and right here, as it seems to me, is the root of the whole matter. I do not call it logical to describe the decrease in the mortality exclusively to the antitoxin treatment, and not to pay any attention to the possibility that the exclusion of other drugs might have something to do with it. This point ought to be investigated first, for we can not deny the fact that the animal serum is more related to us and less harmful to the system than the chemicals are, and it is logical to conclude that the exclusion of the greater evil must have a favorable effect on the mortality.

"Every physician knows that there are a great many cases which change for the better quite unexpectedly," says Dr. Strueh, "and I am sure that this fact has a great deal to do with many a brilliant result of antitoxin treatment. An illustration of this view I lately received from a brother physician and enthusiastic believer in serum-therapy. His sixteen-year-old boy became suddenly sick with high fever, swelling of the maxillary glands, difficulty in swallowing, and thick coating of the tonsils. The doctor obtained some antitoxin late in the evening, but postponed the injection until the next morning, when it was no longer necessary, the boy being practically well. The fever was gone, the maxillary glands were painless and had greatly decreased, and the membrane was almost gone. The case would have been taken as a convincing proof of the efficiency of antitoxin, if it had been injected; on the other hand, it might have turned the tide against recovery. Similar cases are certainly in the mind of every physician."

In our experiments on animals, in injecting various "cultures" directly into the circulation, there is always more or less disturbance of the system, and, not infrequently, serious disease. Even so pure and precious a substance as saliva, which is secreted from the blood by the salivary glands, a fluid so useful in the first stage of digestion, and which passes harmlessly into the stomach in considerable volume; even this fluid, when injected directly into the circulation in the way that antitoxin, so called, is employed, causes considerable disturbance, and, in some instances, a fatal result. The difference between a mild form of disease and a fatal one in these cases is, doubtless, a question of the differing conditions of the subjects, some having greater power of resistance to disease-producing causes. The same principle applies in the matter of vaccination, and in the injection of antitoxin. It is only a rare occurrence, for example, that vaccination causes the death of the subject; it always produces considerable physical disturbance, feverishness, more or less severe local inflammation, etc.; whereas, a much larger

amount of the virus might be taken into a healthy stomach, along with or without food, and no sign of disorder result, the gastric juice being about the most powerful germicide and disinfectant known. Whatever the local or general immediate effects of this procedure may be, the remote evil effects none of us can ever, with any degree of certainty, predict. However, no matter how one may regard the procedure of injecting vaccine virus, or antitoxin, into the blood of any one, well or sick, surely no one would ever dream of calling it a hygienic measure. It must, on general principles, be held as in and of itself unhygienic, and it will, doubtless, be the final conclusion of all scientific men that, upon the whole, we had better pin our faith to hygienic rather than unhygienic treatment, whether for prevention or cure.

It has recently been suggested by a physician, a believer in the antitoxin scheme, that a law be passed making punishment for certain crimes optional with the convicted—either imprisonment or inoculation with certain disease germs—for, as he maintains, antitoxin should be produced from human beings, and not animals. He remarks that "this would solve the problem for all time." A newspaper writer remarks that it might also introduce a few new problems. We might ask what would be the matter with trying it on the doctors themselves? For myself, I make use of no medicament or procedure that I would not feel perfectly safe in applying in my own person or that of any dear member of my family, sick or well. On the other hand, nothing could possibly ever induce me to inject either the virus of cow-pox or the serum of the poisoned horse or criminal into the circulation of my enemy, even, for I am not of a revengeful disposition.

W. R. Hadwen, M. D., L. R. C. P., M. R. C. S., etc., an eminent British physician, is the author of a book, now in its fourth edition, treating in an entirely impartial way the question of the antitoxin treatment for diphtheria. The statistics are taken from the Registrar-General's Returns, and are very interesting and, as it seems to me, convincing. We read:

"Taking the mortality returns for the ten years antecedent to the introduction of antitoxin (1885-1894), we find, on comparing them with the ten years subsequent thereto (1895-1904), that the former period shows a mortality from diphtheria of only two hundred per million persons living, against two hundred and thirty-five in the latter. Throughout the whole decennium, from 1871-80, the average mortality per million persons living, from diphtheria, did not rise above one hundred and twenty-one. No such low mortality is seen throughout the whole antitoxin period, from the date of its introduction ten years ago, until the present time."

Diphtheria is shown to be an epidemic disease. It comes and goes, as epidemics do. "A decline set in in the year 1894, that is, twelve months before antitoxin was introduced into this country (England and Wales), the total diphtheria mortality of that year being eight thousand seven hundred and seventy-four; in the year 1896 (when antitoxin was in almost universal use) the mortality again rose to eight thousand nine hundred and ninety-three, and, although in the two following years a slight reduction occurred, yet it again rose in 1899 to the heavy total of nine thousand two hundred and five, and in 1900, that is five years after the introduction of antitoxin, the mortality had reached nine thousand three hundred and forty-five—the highest year but one upon record."

"To say, in the face of these figures, that antitoxin has rendered diphtheria 'a harmless disease,' as has been repeatedly asserted by medical apologists who have never studied the subject, is to deliberately seek to blind the eyes of the public to the actual facts, and to mislead the profession as to the true causes of the disease. Until those causes are fairly faced and investigated, and the medical mind diverted from the hallucination of the antitoxin fetich to the contemplation of more solid and scientific methods, we must go bungling on with ever-recurring epidemics, oblivious to the lessons which they emphatically teach. * * * It is not by adding disease to disease that the evil of diphtheria will be combated, but it is by the removal of the dark, damp, ill-ventilated slums which infest our towns and cities; by letting light and air

into the over-crowded and unsanitary dwellings of the poor, and by the inculcation of lessons of cleanliness and hygiene among the people."

Right here at home we have evidence that to befoul the circulation with the serum of the blood of a poisoned horse is what we would naturally expect, unwholesome for sick or well folk. Two brothers, law students at Boston University, a freshman and a senior; the younger man was taken ill with some throat symptoms, was given antitoxin, and was dead within forty-eight hours. The brother who had slept with him was given the drug for prevention. His heartbeat dropped below fifty in short order, and his condition was so depressed that the doctor didn't dare give him any more. "I wouldn't have taken it anyway, if he wanted me to," said the young man.

Ernest Langerhaus, the young son of Dr. Langerhaus, medical director of the Moabite Hospital, in Berlin, was killed in perfect health by an injection of Behring's "immunizing serum!" This sad occurrence has convinced one medical man that this serum is best avoided; but must they all be convinced in this way?

While no one could more than the present writer rejoice over the discovery of a sure and speedy cure for diphtheria, still, believing, as he does, that the antitoxin treatment is unhygienic and altogether irrational, he notes with great satisfaction that already there comes from high sources stern opposition to its employment as a remedy for diphtheria.

Says the *Medical Record:* "A paper of the greatest importance was read at a recent meeting of the Berlin Medical Society by Dr. Hansemann. It carries especial weight, because it is announced by an assistant of Professor Virchow, and his work and conclusions are presumably indorsed by the dean of modern pathology."

Dr. Hansemann came out in flat contradiction of the alleged properties and powers of the Behring immunizing serum. He then proceeded to describe the three qualities claimed for the antitoxin, namely, its therapeutic action, its harmlessness and its immunizing power. He said that the present statistics give an erroneous impression (as already shown by Gottstein, in his recently published pamphlet), as many children suffering from lighter forms of throat trouble are now sent to the hospital to be treated with serum, thus swelling the proportion of "cured" cases, which would, he said, otherwise not be higher than the usual average. He said serum injections could by no means be considered harmless, as affections of the kidneys had frequently followed—in one case more severe in type than had ever yet been observed after diphtheria. And, by the way, the same principle applies in the matter of the Pasteur anti-rabies serum.

An editorial in THE MEDICAL BRIEF says: "We call the attention of our readers to the article on antitoxin, in this issue, by Lennox Browne, of London, the greatest laryngologist in the world. He reviews the subject ably and impartially, and proves by unprejudiced, unperverted statistics, that antitoxin is not, and has never been, of the slightest service in the treatment of diphtheria. We hope every doctor will read the article carefully."

In the article alluded to, which is an exhaustive study of every phase of the question, statistical and otherwise, Dr. Browne arrives at the same conclusions as Dr. Hansemann. He alludes to an article in the *British Medical Journal*, and comments upon a portion of it as follows: "I regret to note that both in the article to which I am referring, as well as in others of less authoritative origin, fatalities from inflammation and arrested secretion of the kidneys, from broncho-pneumonia, and from cardio-respiratory paralysis, are all made to occupy a secondary position as a cause of death, albeit they are all a direct result of the poisoning of the system with the toxines of diphtheria." If such views as these are to obtain, surely the very word "antitoxin" is a misnomer.

The *British Medical Journal* cites two cases of death from antitoxin: The first was reported by Dr. Axel Johanessen to the Medical Society of Christiana. The patient was a boy in good health, who received an injection for preventive purposes. He was taken soon after with a sharp diarrhea, grew progressively worse, and died on the tenth day after injection.

THE MEDICAL BRIEF of June, 1896, says: "Deaths from diphtheria serum are multiplying thick and fast. Since the publica-

tion of the Langerhaus case, Dr. Asch has reported through the *Vossische Zeitung* several similar instances, one of them the daughter of a high Prussian medical official who was ill for three months after inoculation. Death should be always considered among the possibilities where a poison is injected directly into the circulation, and reaches the heart before its virulence has been, in any way, diminished. Diphtheria serum is a poison of animal origin, and nothing else. In the majority of cases, it so rouses the system that it is speedily eliminated, but where the heart is congenitally deficient or weakened by a septic disease, the injection of the serum is a most dangerous procedure. Such benefit as may be derived from the antiseptics it contains can not count against the very real dangers lurking in the poisoned horse water."

Another thoughtful physician says: "The major portion of antitoxin's favorable statistics is drawn from cases of diphtheria which 'never went through the formality of occurring.'"

It is absurd to claim that diphtheria is now more prevalent than in former years; that would imply a decline in personal and general sanitation, when we know the reverse to be true. The misleading thing at this time is that about all cases of sore throat are called diphtheritic, and antitoxin is generally employed; hence, the alleged lessened per cent of mortality, though we have to confess that, as shown above, we have epidemics of diphtheria, with more deaths in number since antitoxin than before. It is easy to show how a thirty per cent death-rate is figured out as only six per cent: Say twenty cases of true diphtheria, with eighty cases of more or less severe sore throat; in these one hundred cases six deaths, and called six per cent, when it is really thirty per cent of the actual cases of diphtheria.

[Written for the MEDICAL BRIEF.]

All Licensing Boards are Unconstitutional and Void.

BY R. C. BAYLY, A. M., M. D., D. S. T.,
Decatur, Ill.

The Supreme Court of Illinois has decided that the Pharmacy Act of 1899 is void. No person in the State could compound medicines or sell at retail drugs or medicines without a license from the State board.

The act is declared to be invalid on the ground of discrimination. The Court says: "A law which thus invests any board or body of officials with a discretion which is purely arbitrary, and which may be exercised in the interests of a favored few, is invalid. The Constitution of the State says that the Legislature shall never grant to any corporation, association, or individual any special or exclusive privileges, immunity or franchise whatever." The act to regulate the practice of medicine in Illinois has no more foundation, in law, than that of pharmacy. The fact is, no man or body of men can regulate the practice of medicine but physicians themselves. The practice of medicine does not come within the province of legislative authority. And as to the statement by those who put on foot the act that the people asked them for protection against medical quacks, it is false. No legislature was ever called upon to put a tax upon the people for the suppression of quacks. The Legislature of Illinois enacted an anti-trust law, with this proviso: "Penalties against consolidation shall not be held to apply to live stock and agricultural products in the hands of the producer or raiser." Such an exception, says the Supreme Court, in declaring the law unconstitutional, "Is absolutely forbidden by the fourteenth amendment to the Federal Constitution."

The Court further said: "No legislature can divide those in trade into two classes, and make criminals of those in one class while allowing another and favored class engaged in trade to do the same thing with impunity."

The Medical Practice Acts divide practitioners of medicine into two classes, and makes criminals of the one class for doing

that which the other class may do with impunity. In almost every State, one class of physicians is permitted to practice medicine without passing a technical or other examination, appointed by the State. They are simply required to file a diploma with the clerk of the county in which they propose to do business. All who attempt to compete with them on equal terms are made criminals in the sight of the law. Such discrimination, or exception of this kind, is "absolutely forbidden by the fourteenth amendment."

And if a discrimination, or exception of this kind, is "absolutely forbidden in one trade or business, it is, by all rules of legal interpretation, equally forbidden in all trades and avocations." The professional man has never been made an exception to the general rule by the National Government or the United States Supreme Court. The States only have attempted to do these devilish things. On this subject Mr. Justice Field said: "With the adoption of the amendment the power of the States to oppress any one under any pretence, or in any form, was forever ended, and henceforth all persons within their jurisdiction could claim equal protection under the laws. The fact is, and the law is, that no State, even with process of law, shall deny to any one within its jurisdiction the equal protection of the laws."

In 1892, Mr. Justice Harlan, on behalf of himself and Mr. Justice Brewer, said: "I fully concur with Mr. Justice Field that since the adoption of the fourteenth amendment no one of the fundamental rights of life, liberty or property, recognized and guaranteed by the Constitution of the United States, can be denied or abridged by a State in respect to any person within its jurisdiction."

Since the publication of the "Legal Status of Doctors Everywhere Under the Flag," quite all the courts have decided that the position therein declared is correct whenever the gross illegality of the Medical Practice Acts have been adjudicated; and it is confidently believed by all thinking, free people, who are sufficiently educated on the subject, that the tax-payers of the States will put a stop to all legislation in support of arbitrary State boards that have been established contrary to law and the State Constitution for the support of political doctors who, not having qualifications to make a living by practice, have resorted to political fraud to get bread out of the public crib.

These statements of law and facts show that the so-called Medical Practice Acts and examining boards now in the hands of the men that work them for greed, are a menace to life, liberty and property, and have already ruined hundreds of physicians and their families.

An old doctor, who had practiced his profession honorably and successfully in an Eastern city, undertook to settle in the West, where land was cheap, and there continue the practice for a living, spent what he had, and the medical board of examiners, refusing to allow him to enjoy his professional rights, denied him a certificate, and, as a free, law-abiding citizen under the Constitution and laws, with his wife, in their old days, died for want of the necessities of life. Thousands of doctors have suffered the same way to gratify the pretext of "protecting the dear people."

Examination Questions and Answers Missouri Medical Examining Board.

ANATOMY—Answered by Hansell Crenshaw, M. D.

1. Give description with points of ossification of (a) parietal, (b) frontal, (c) occipital bones and (d) femur.

ANSWER.—This question is fully four times too exhaustive. (a) The parietal bone is a quadrilateral curved plate, having an internal surface, four borders, and four angles. Features of the internal surface: (1) concave surface, (2) meningeal grooves, (3) eminences and depressions for brain convolutions, (4) pachionian depressions, (5) lateral sinus groove. (6) perietal foramen, (7) superior longitudinal sinus groove. Features of external surface: (1) convex surface, (2) parietal eminence, (3) temporal ridges, (4) parietal foramen. Superior border: (1) serrated to join the opposite bone, (2) grooved on its under aspect for superior longitudinal sinus. Inferior border: (1) bevelled externally in front, to be overlapped by the great sphenoidal wing, and the squamous portion of the temporal bone, (2) serrated posteriorly to join the mastoid part of the temporal. Anterior border: (1) external serrations above for the frontal bone, (2) internal serrations below, also for the frontal. Posterior border: Serrated for the occipital bone. Angles: (1) the anterior inferior is

the most prominent, while (2) the two upper angles participate in closing the anterior and posterior fontanelles. Ossification—from a single central nucleus, beginning about the seventh week. (b) The frontal bone consists of a vertical and a horizontal plate, each having an internal and an external surface and border. Features of the external surface of the vertical plate: (1) Convex surface, (2) two frontal eminences, (3) nasal eminence, (4) superciliary ridges, (5) metopic suture. Features of the internal surface of the vertical plate: (1) concave surface, (2) frontal sulcus and crest, (3) foramen ceacum, (4) pacchionian depressions, (5) meningeal grooves. Features of the external surface of the horizontal plate: (1) The ethmoidal notch separates this surface into two orbital plates, (2) the orbital plates are triangular and concave, (3) the margins of the ethmoidal notch present broken ethmoidal cells, (4) the nasal spine projects from the anterior end of the ethmoidal notch, (5) the lachrymal fossæ. Features of the internal surface of the horizontal plate: (1) Two convex surfaces separated by ethmoidal notch, (2) undulations for the convolutions of the cerebrum. Borders—the border of the vertical plate is (1) semi-circular, (2) beveled interually above to overlap the parietal bones, (3) beveled internally below to underlap the parietal bones, (4) thickened at the lower ends to join the great sphenoidal wings. The posterior border of the horizontal plate articulates (1) with the lesser sphenoidal wings, and (2) in the ethmoidal notch with the ethmoid bones. Ossification—from two nuclei at the frontal eminences, beginning about the eighth week. (c) The occipital bone is a curved diamond-shaped plate, having an internal surface, an external surface, four borders, and four angles. Features of the external surface: (1) Convex surface, (2) external occipital protuberance, (3) external occipital crest, (4) superior and inferior curved lines, (5) the foramen magnum transmitting the medulla oblongata and membranes, spinal accessory nerves, vertebral arteries, spinal arteries, and check ligaments, (6) anterior condyloid foramina, transmitting the twelfth nerves and meningeal arteries, (7) the posterior condyloid foramina, (8) the pharyngeal ridge, (9) the condyles. Features of the internal surface: (1) Concave surface, (2) inner openings of all foramina noted on external surface, (3) a crucial grooved ridge for lateral and longitudinal sinuses, dividing the surface into four fossæ, (4) internal occipital protuberance. Borders: (1) The superior borders join the parietal bones forming the lambdoid sutures, (2) inferior borders articulate with temporal bone, and are marked halfway by jugular processes. Angles: These are superior, two lateral, and inferior. Inferior angle constitutes the bassilar process, which is continuous with the sphenoid bone. Ossification—from four centers beginning about the eighth week. (d) The femur is a long bone, consisting of an upper extremity, a lower extremity, and a shaft. Upper extremity: It comprises a head, neck, greater trochanter and lesser trochanter. The head, directed upward, inward, and forward, is hemispherical, and coated with cartilage. It articulates with the acetabulum, and presents a small fossa at about the center of the articular surface for the ligamentum teres. The neck is a strong bar, serving to join the head to the shaft at an angle, approximately, one hundred and twenty-five degrees. Its vertical diameter is greater than its thickness, and it is widest where it joins the shaft. Its junction with the shaft is marked anteriorly by a ridge which terminates above in the tubercle. Posteriorly, the intertrochantic ridge crosses the widest part of the neck. In front of the upper part of this line is the digital fossa. The trochanter major is a large cuboid process surmounting the shaft, so as to overhang the digital fossa. Its outer surface is rounded, and presents an oblique line passing from the upper back angle to the lower front angle. This process presents, also, an oblong anterior surface, a superior border and a posterior border, the latter being the upper part of the intertrochanteric ridge. The trochanter minor is a prominent process situated at the back of the shaft, about two and a half inches below the greater trochanter. (Second appearance of a description of the upper extremity of the femur in this journal). Features of the lower extremity: (1) The cartilage-covered condyles, (2) inter-condyloid notch, (3) articulation with the tibia and patella. Features of the shaft: (1) Cylindrical shape, (2) linea aspera behind, (3) internal and external supra-condylar lines being lower expansions of the linea aspera, (4) glutea ridge and linea quadrati, being upper expansions of the linea aspera, (5) nutrient foramen. Ossification—from one primary and four epithysil centers, beginning in the seventh week.

2. Describe superficial and deep palmar arches, and the brachial artery—giving branches and relationships.

ANSWER.—The superficial palmar arch is a loop, formed by the anastomosis of the superficial branch of the ulnar artery with the volar branch of the radial artery. The convexity of the arch is toward the clefts of the fingers. The junction with the volar artery is just above the cleft of the thumb. The arch in front lies behind the skin and superficial fascia, being crossed from within outward by the palmaris brevis, palmar branch of ulnar nerve, palmar fascia, and palmar branch of median nerve. Behind it rests upon the flexor tendons, muscles of the little finger, and branches of the ulnar of median nerves. Branches—four digital, muscular and cutaneous. A line drawn across the palm level with the cleft of the thumb, roughly locates the arch. The deep palmar arch is a loop, formed by the anastamosis or the terminal branch of the radial artery with the deep branch of the ulnar; this arch is covered by the deep flexor tendons, and lies one-half inch nearer the wrist than the superficial arch; its branches are three palmar interosseous, recurrent carpal, posterior perforating. The brachial artery is a continuation

of the axillary, and passes down the arm from the teres major to center of the bend of the elbow; important relations—in front, skin and superficial fascia, the median nerve in the middle third of the arm, median basilic vein at lower part. Behind—triceps, Coracobrachialis, musculo-spiral nerve, superior profunda artery. Laterally—Median nerve is on the outer side above and inner side below. Ulnar and internal cutaneous nerves are an internal relation above. The basilic vein is a little to the inner side. Branches—superior profunda, inferior profunda, anastomatica magna, nutrient, muscular, terminal (namely, radial and ulnar arteries).

3. Describe brachial plexus and great sciatic nerve?

ANSWER.—(The formation of the brachial plexus is best shown by a diagram, and I advise candidates to submit a labeled diagram, instead of a description). (1) The brachial plexus nearest the median line consists of the parallel trunks of the fifth cervical, sixth cervical, seventh cervical, eighth cervical, first thoracic, second thoracic, and third thoracic nerves. (2) Passing outward, the fifth and sixth cervical unite, the eighth cervical and first thoracic unite, the seventh cervical divides, and a communicating branch joins the first and second thoracic. (3) An inch further out the upper division of the seventh cervical has joined the trunk formed by the union of the fifth and sixth cervical, while said trunk has given off a large branch, which passes down to unite with the lower division of the seventh cervical, and with a small branch from the eighth cervical. Thus the plexus at this point consists of three large trunks or cords—the upper one formed by the fifth, sixth, and upper half of the seventh cervical nerve; the middle and deeper one, formed by the lower division of the seventh cervical, a large branch from the united fifth and sixth cervical, and a small branch from the eighth cervical; and the lower one formed by the union of the eighth cervical and first thoracic; while below these three trunks are the second thoracic and third thoracic, or intercostal branches. (4) Further out, the upper cord divides into the musculo-cutaneous nerve, and the outer head of the median nerve: the lower cord divides into the inner head of the median nerve, the ulnar nerve, the internal cutaneous nerve, and the nerve of Wrisberg; while the middle trunk divides into the circumflex and musculo-spiral nerves. The two lower thoracic, or intercostal nerves, join to form a loop which connects with the nerve of Wrisberg. "The great sciatic nerve is the continuation of the upper band of the sacral plexus." It passes from the pelvis through the sacro-sciatic foramen, descends through the gluteal muscles, passing between the great trochanter and ischial tuberosity, and thus down the back of the thigh, terminating in the popliteal space, by dividing into the external and internal popliteal. It gives off muscular branches to the biceps, semi-membranosus and aducta magnus.

4. Describe the portal circulation.

5. Name flexor muscles of hand, extensor muscles of same.

ANSWER. — Flexors — flexor carpi radialis, flexor carpi ulnaris, flexor carpi radialis longoir, palmaris longus. Under certain circumstances the following may be included: Flexor sublimis digitorum, flexor profundus digitorum, flexor longus policis, flexor brevis policis. Extensors—extensor carpi radialis longoir, extensor carpi radialis brevoir, extensor carpi ulnaris. Secondarily, the extensor ossis metacarpi polisis, extensor communis digitorum, extensor minimi digiti, extensor longus polisis, extensor brevis polisis.

NOTE.—Modern anatomists do not cassify these muscles as flexors and extensors of the hand, however.

6. Describe Scarpa's triangle, popliteal space.

ANSWER.—Scarpa's triangle is an area on the front of the thigh, bounded as follows: At the base by Poupart's ligament, internally by the adductor longus, externally by the sartorius; superficially, by the skin and fascia; underneath, by the iliacus, psoas, pectineus, adductor longus. Important contents—Femoral artery and vein, and anterior crural nerve. The popliteal space is a trapezoid space behind the knee joint, bounded externally by the tendon of biceps femoris above, and by the outer head of the gastrocnemius below; and bounded internally by the inner hamstring tendon above, and by the inner head of the gastrocnemius below. Important contents: Popliteal artery, vein and nerves.

7. Describe (a) superior longitudinal sinus, (b) lateral sinus, (c) torcular herophili.

ANSWER.—(a) The superior longitudinal sinus is a venous channel, resting in a groove which passes from the crista galli backward along the inner surface of the skull to the internal occipital protuberance. The groove is converted into a canal by fringed processes from the dura mater, called the falx cerebri. (b) The lateral sinuses are similar channels which pass from the internal occipital protuberance outward and forward to the jugular foramina. (c) The torcular herophili is a depression at the point of confluence of the lateral and longitudinal sinuses.

8. Give a short description of pericardium.

ANSWER.—The pericardium is a fibrous sac which envelops the heart. It is lined with an endothelial membrane, which is reflected onto the surface of the heart.

9. Give a short description of pleura.

ANSWER.—The pleura is a double fibrous sac enveloping the lung. One layer of the pleura is attached to the chest wall, while the other layer is reflected onto the surface of the lung. The opposing surfaces of these layers are endothelial, and secrete a serous fluid.

10. Give anatomy of kidney.

ANSWER.—The kidney consists of an outer fibro-muscular capsule, a cortex, and a medullary portion. In the cortex are the capillary tangles, known as the glomeruli, which receive

bules begin from pouches around the glomeruli and the tubes, after a tortuous course toward the center of the kidney, dip down as the loopes of Henle, return to the cortex, and empty into large, straight collecting tubes, which empty by clusters into the central cavity or pelvis of the kidney. This pelvis connects with the ureters, which convey the urine to the bladder. The medullary portion of the kidney is made up, largely, of the collecting tubes.

CHEMISTRY—Answered by Hansell Crenshaw, M. D.

1. (a) Give specific gravity of albuminated urine. (b) Also two tests for albumen in the urine.

ANSWER.—(a) Above 1.025. (b) Boil suspected urine, to precipitate albumen, and add a few drops of nitric acid to distinguish precipitate from phosphates. Or add urine gradually above a strata of nitric acid, to produce albuminous ring at point of contact.

2. (a) What are the antidotes for bichloride of mercury? (b) Treatment (chemically) of poisoning from same.

ANSWER.—(a and b) Albumen, as white of egg.

3. Give properties of nitrous oxide, or "laughing gas."

ANSWER.—Invisible, sweetish, inflammable gas, capable of producing temporary anesthesia.

4. What is the chemical composition of pancreatic juice?

ANSWER.—Pancreatic juice is above ninety per cent water, and contains the following organic ferments, besides sodium chloride and other inorganic salts: Trypsin, steapsin and amylopsin.

5. Give chemical characteristics of hydrate of chloral.

ANSWER.—It is a neutral, unstable, organic compound, containing water of crystallization, and classed as a chlorine derivative of acetic aldehyde.

PRACTICE—Answered by Hansell Crenshaw, M. D.

1. Give etiology, symptoms and treatment in pyelitis.

ANSWER.—Cause may be renal calculus, extension from urethritis or cystitis, tuberculosis, infectious fevers, exposures, etc. Symptoms: Lumbar pain, pus cells, red corpuscles, mucus, etc., in the urine. Treatment: Rest in bed, liquid diet, diuretics, saline cathartics.

2. Give etiology, symptoms and treatment of acute ascending (Landry's) paralysis.

ANSWER.—Cause: Probably degeneration of motor nerve centers, beginning first with those controlling the lower extremities. Symptoms: Palsy, beginning in the feet and extending upward, so as to involve all the muscles within a week, when the medulla is affected, and the patient dies.

3. Give etiology, symptoms and treatment of neumothorax.

ANSWER.—Cause: Rupture or perforation of the pleural sac from any cause, such as traumatism, tuberculosis, malignant disease, etc. Symptoms: Bulging of intercostal spaces, sudden pain, dyspnea, cyanosis, etc. Treatment: Adhesive strapping of chest, stimulants, and symptomatic treatment.

4. Give etiology, symptoms and treatment of dilatation of the heart.

ANSWER.—Cause: Any condition putting excessive work on the heart, such as athletics, mitral or tricuspid insufficiency, aortic stenosis, etc. Symptoms: Displacement of apex beat from the median line, shortness of breath, enlarged cardiac dullness, etc. Treatment: Rest and exclusion of excitement. Loss of compensation calls for digitalis.

5. How would you diagnose cerebral hemorrhage?

ANSWER.—Diagnostic signs are sudden convulsion or unconsciousness, flushed face and blue lips, hemiplegia, coma, lowered temperature, etc.

6. Give treatment and general management in such case.

ANSWER.—I would prescribe rest in bed, with head elevated; ice cap, symptomatic treatment, and prohibition of stimulants.

7. What are the most reliable signs of death?

ANSWER.—Cessation of the heart's action. Redness under a ligature around the finger indicates that the heart is still acting, though possibly too lightly to be otherwise observed.

8. What is meant by sympathetic disturbance?

ANSWER.—Communication of abnormality from one organ to another by means of nervous connection. For instance, the inflammation of the right eye following injury, etc., to the left eye.

9. Discuss autoinfection.

ANSWER.—Autoinfection refers, principally, to the absorption from the alimentary tract of poisons developed therein during digestion, which poisons are normally not absorbed. The symptoms are headache, vertigo, nausea, lassitude, insomnia, etc. The treatment is fasting, then light diet; intestinal antiseptics, such as salol and eliminants, such as calomel.

10. Give symptoms and treatment of Graves' or Basedow's disease.

ANSWER.—Symptoms: Palpitation, goiter, exophthalmos, tremors, Græfe's sign. Treatment: Rest, avoidance of excitement; also thyroid extract, bromides, digitalis, and, sometimes, operative procedures.—*State Board Journal of America.*

(To be continued.)

Inclosed find one dollar for THE MEDICAL BRIEF for one year. I don't want to miss a copy, as the BRIEF is useful information, and every copy is worth the price. —C. M. THARP, M. D., Kingston Mines, Ill.

Book Notices.

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, and the kindred branches, with their pronunciation, derivation, and definition. Including much Collateral Information of an Encyclopedic Character. By W. A. Newman Dorland, A. M., M. D., Assistant Obstetrician to the University of Pennsylvania Hospital, etc. Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc., of Bacilli, Bacteria, Diplococci, Micrococci, Streptococci, Ptomains, Leucomains; Weights and Measures; Eponymic Tables of Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc. Fourth edition, revised and enlarged. Philadelphia and London: W. B. Saunders Co. Price, flexible morocco, $4.50; with thumb index, $5.00.

This work has had a wonderful sale, and richly deserves it, and here comes a new edition with two thousand new words. It is complete and should have the praise that such works merit. Secure a copy and take our word for it that you will be pleased.

REFRACTION OF THE EYE. Its Diagnosis and the Correction of Its Errors. With a Chapter on the Use of Prisms. By A. Stanford Morton, M. B., F. R. C. S. (Eng.), Surgeon to the Moorfields Ophthalmic Hospital; Ophthalmic Surgeon to the Great Northern Central and to the Italian Hospitals, etc. Seventh edition. Philadelphia: P. Blakiston's Son & Co. Price, $1.00.

A work of this nature will enable the general practitioner to diagnose these conditions of the eye, and when they get beyond the general practitioner's treatment it would be well to consult a specialist.

THE MEDICAL EPITOME SERIES. NOSE AND THROAT. By J. B. Ferguson, M. D., of the New York Post-Graduate Medical School. Philadelphia and New York: Lea Brothers & Co. Price, $1.00.

The object of this work is to present in concise form a practical knowledge of the diagnosis and treatment of the various diseases ordinarily found in the nose and throat. That this has been accomplished for the use of the undergraduate and post-graduate student is readily apparent.

ATLAS AND TEXT-BOOK OF HUMAN ANATOMY. By Dr. Johannes Sobotta, Professor of Anatomy in the University of Würzburg. Edited, with additions, by J. Playfair McMurrich, A. M., Ph. D., Professor of Anatomy in the University of Michigan. In two volumes. Volume I, Bones, Ligaments, Joints and Muscles, with three hundred and twenty illustrations, mostly in colors. Volume II, the Viscera, Including the Heart, with two hundred and fourteen illustrations, mostly in colors. Philadelphia and London: W. B. Saunders Co. Price $6.00 per volume in cloth, and in half-morocco, $7.00 per volume.

These volumes are the richest in colored illustrations and in text of any work that has ever appeared on our review table. It would be superfluous to say what one could expect in a work on human anatomy, but we must say, in justice to this work, that nothing is lacking to appeal to the most critical student of medicine. It must be seen to be fully appreciated.

A MANUAL OF PRESCRIPTION WRITING. With a Full Explanation of the Methods of the New York Obstetrical Society. Revised by Edward Cox Mann, M. D., Lecturer on Obstetrics Medical Department of the University of Buffalo, Fellow of the Buffalo Academy of Medicine. Sixth edition, revised, enlarged and corrected acording to the U. S. Pharmacopœia of 1906. New York and London: G. P. Putnam's Sons. Price, $1.00.

When a book has reached its sixth edition, it would seem that it was really needed. It has been revised to conform to existing conditions, and should hold its former popularity, and does not call for any effulgent comment from us. It is fixed in the minds of all who have seen it.

AIDS TO MEDICAL DIAGNOSIS. By Arthur Whiting, M. D., M. R. C. P., Physician to the Tottenham Hospital and Assistant Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest. Lecturer in and Dean of the Northeast London Post-graduate College. New York: William Wood & Co. Price $1.00.

This work is intended for those who already possess a knowledge of systematic medicine, whether advanced medical students or post-graduates. This book will aid materially in cultivating the ability to diagnose properly. Proper diagnosis is half the battle against disease.

THE PRACTICAL MEDICINE SERIES, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of Gustavus P. Head, M. D., Professor of Laryngology and Rhinology Chicago Post-Graduate Medical School. Vol. X, Skin and Venereal Diseases, Nervous and Mental Diseases. Edited by W. L. Baum, M. D., Hugh T. Patrick, M. D., William Healy, A. B., M. D. Chicago: The Year Book Publishers. Price, $1.25; series of ten volumes, $10.00.

While this series is published primarily for the general practitioner, at the same time the arrangements are such that separate volumes on special subjects can be purchased if the complete set is not desired. The entire ten volumes in a library certainly is a great acquisition for reference.

AIDS TO THE DIAGNOSIS AND TREATMENT OF DISEASES OF CHILDREN. By John McCaw, M. D., R. U. I., L. R. C. P. (Edin.), Physician to the Belfast Hospital for Sick Children. Third Edition. New York: Wm. Wood & Co. Price $1.25.

The favorable reception from the press that this work received in the former editions, shows that this one should be more royally entertained because the author has enlarged its scope by adding much new matter. There is nothing so encouraging to an author than an urgent request for a new edition of a work that merits its continuance by the approval of the profession and the press. It certainly has merit.

ESSENTIALS OF OBSTETRICS. By Charles Jewett, A. M., M. D., Sc. D., Professor of Obstetrics and Gynecology in the Long Island College Hospital, etc., assisted by Harold F. Jewett, M. D. Third edition, revised and enlarged. Eighty illustrations and five colored plates. Philadelphia and New York: Lea Brothers & Co. Price $2.25.

This book will serve a beneficial purpose to the student who desires the essential facts in obstetrics, and is fully in keeping with the practical teaching in his college course. A thorough reading of this volume will lend aid in examinations. We commend it to all our student friends, and we have quite a few.

AIDS IN DENTAL SURGERY. By Arthur S. Underwood, M. R. C. S., L. S. D. (Eng.), and Douglas Gabell, M. R. C. S., L. R. C. P. (Lond.), L. D. S. (Eng.). Second edition. New York: William Wood & Co. Price $1.00.

In this edition two new chapters on Bacteriology and the Hygiene of the Mouth have been introduced, and the whole work has been brought up to date. This is an aid to the physician and dentist.

LEADERS FOR THE USE OF SULPHUR, with Comparisons. By E. B. Nash, M. D., author of Leaders in Homeopathic Therapeutics, Reginal Leaders, and Leaders in Typhoid Fever. Philadelphia: Boericke & Tafel. Price, $1.10.

The author lays great stress on the constitutional virtue of sulphur, and says that Hahnemann placed a high estimate on it as the chief antipsoric. It would be well for physicians to read up on the subject of particular remedies, and thus gain much knowledge as to its utility.

SAUNDERS' POCKET MEDICAL FORMULARY. By William M. Powell, M. D., Author of "Essentials of Diseases of Children;" Member of Philadelphia Pathologic Society. Containing one thousand eight hundred and thirty-one formulas from the best known authorities. With an appendix containing Posologic Tables, Formulas and Doses for Hypodermic Medication, Poisons and their Antidotes, Diameters of the Female Pelvis and Fetal Head, Obstetric Table, Diet-lists, Materials and Drugs used in Antiseptic Surgery, Treatment of Asyphyxia from Drowning, Surgical Remembrancer, Tables of Incompatibles, Eruptive Fevers, etc., etc. Eighth edition, adapted to the new (1905) Pharmacopœia. Philadelphia and London: W. B. Saunders Company. In flexible morocco, with side index, wallet and flap, $1.75.

TROPICAL MEDICINE. With Special Reference to the West Indies, Central America, Hawaii and the Philippines. Including a General Consideration of Tropical Hygiene. By Thomas W. Jackson, M. D., Lecturer on Tropical Medicine, Jefferson Medical College, Philadelphia; Member of the American Society of Tropical Medicine; Lately Captain and Assistant Surgeon United States Volunteers. One hundred and six illustrations. Philadelphia: P. Blakiston's Son & Co. Price, $4.00.

THE ELEMENTS OF THE SCIENCE OF NUTRITION. By Graham Lusk, Ph. D., M. A., F. R. S. (Edin.), Professor of Physiology at the University and Bellevue Hospital Medical College, New York City. Illustrated. Philadelphia and London: W. B. Saunders Co. Price, $2.50.

Editorial.

Chemistry—Its Advances.

The history of chemistry, proper, begins with Robert Boyle, who taught, as its main object, the acquisition of a knowledge of the composition of bodies. The conception of this aim marks the date from which chemistry may be regarded as a science. This merit belongs to an Anglo-Saxon (Boyle). Next in line comes a Frenchman, named Lavoisier, who gave the stepping-stone of advance. Then down through the ages to Paracelsus, Van Helmont de la Böe Sylvius, Tachenius, and others of note, came the period of medical, or iatro-chemistry, and then from the middle of the seventeenth century iatro-chemistry gave way to other branches. Physical chemistry, with the accompanying doctrine of affinity, has made immense strides, and has greatly broadened its foundations during the last two decades. At last the key that opened the whole advance is combined in the elegant pharmaceuticals of today.

What Food is Needed?

Doctor, suppose you have a patient who is troubled with indigestion, so that when he eats food it passes off by the bowels practically unchanged, and the patient remains weak. The bowels are tender and congested; moving too frequently.

You would prescribe medicine for this case, of course, but do you really know what kind of food is best for him? Are you prepared to tell the family just what they should use, and how to prepare it? Some foods are easier of assimilation than others, and the method of preparation still further affects this. When digestion

and assimilation are almost at a standstill such knowledge is at a premium.

It is as much a part of the practitioner's duty to instruct the family about the patient's food as about how to give the medicine, and the practical details of preparation enter largely into the question of results.

The doctor may say that he is neither a nurse nor a cook, that his business is to practice medicine. But the doctor has to press all kinds of material into service as nurses and cooks, and if he knows enough of both to instruct his helpers so that they may co-operate successfully with him, so much the better for patient and doctor.

If you should ask a Chinese doctor what food would be best for the above patient, it is a foregone conclusion that he would say: "Give him boiled rice, and nothing else until the digestive organs are restored to a normal condition." Is this correct?

Now is a good time to ask and to think about this before you are confronted with the actual emergency. What food is needed to tide this patient over his season of weakness, and to set him on his feet once more?

The "Good Man."

There was a man in town yesterday, who formerly worked in Atchison for a hundred dollars a month. He now receives a salary of ten thousand dollars a year, and he doesn't work as hard as he did.

This man is no great genius; he is simply a "good man," and there are thousands of such. Being a "good man" means that a man is industrious, loyal, intelligent and well-behaved. It is easier to be a "good man" than it is to be a bad one. There is a scarcity of "good men," and those who are patient and work away the best they can are always recognized and substantially rewarded. The man who never does his share, who is willing to impose on his office or shop associates, never comes to the front.

The point we desire to emphasize is that it is easier to be a "good man" than it is to be a bad one. You must live, so why not live in the easiest way? The easiest way is to be a "good man." That is, to do your work faithfully, intelligently and honestly and treat yourself and others right.—*Exchange.*

The above teaches the lesson that good men are always in demand.

The good doctor is the one who refuses to be prejudiced, either for or against anything, or to let others govern him. Who reads all sides of a question, and comes to his own conclusions. In his use of remedies the good doctor is not influenced by what others may say about them, but applies the test of merit. When a remedy serves him well he will keep on using it. The good doctor is after results; he wants to cure his patients, and ridiculous distinctions of a sentimental nature can not stop him from using remedies which he knows by experience are good.

Some of the arguments against established remedies, whose worth time and experience have proved thousands of times, are so far-fetched that nothing but a determined and self-interested effort to prejudice the doctor can account for them.

The doctor whose good, common sense controls him in all things is the man who does an ever-increasing practice, and succeeds simply because he deserves to.

Speaks for Itself.

We have received an inquiry from an old doctor friend of ours asking why we do not deny the lies that are told about THE MEDICAL BRIEF and its editor. In reply will say that we do not do so for the reason that THE MEDICAL BRIEF speaks for itself. Compare the BRIEF with any journal that has a lying article in it, and you will find the BRIEF does not suffer from the comparison. As for the editor, lies do not do him any harm; in fact, we doubt whether they ever do anyone harm, from the fact that the liar always overdoes it.

The Real Reason.

In the case of the ethpharmal proprietaries of established reputation, a dollar preparation usually costs the retail druggist about sixty cents a bottle, whilst the so-called pharmacopeia substitutes cost only a few cents. Of course, the latter have no virtue, but the druggist

cares nothing about that; the profit that he makes is the real reason why the druggist recommends the imitation instead of the original. No intelligent physician will prescribe these worthless substitutes.

Bossism.

Bossism is now prevalent in all trades and professions. When a man or a set of men want to boss you, it's always graft. The more ignorant a man is, the easier he is to boss—the more intelligent a man is, the harder he is to boss. By proving itself so hard to boss, the medical profession has shown that it is composed of a very intelligent class, as a rule.

How Kind.

How kind the grafters are to want to persuade you to let them boss you for nothing.

If the druggist is to dictate to the doctor what he shall prescribe, what's the use of doctors?

[Written for the MEDICAL BRIEF.]

Valvular Disease of the Heart.

BY H. K. DUNKLEE, M. D., PH. D.,

Professor of Theory and Practice of Medicine in the Denver Homeopathic Medical College. Denver, Colo.

Since the valves of the heart are so situated as to be circumscribed by a circle the size of a large receiver of the stethoscope, it is impossible to determine in many cases which valves cause a murmur heard faintly in all parts of the precordial region. In order to locate the lesion it is necessary to fix the point of greatest intensity of the murmur, and with which sound of the heart it occurs.

The reason a murmur, due to certain valvular lesions, can be heard with greater distinctness at a given point, is anatomical. Sound is heard with greatest distinctness through a solid medium, hence the column of blood having passed the valves, forms the best medium for conveying the murmur.

The aorta connected with the left ventricle passes to the right and above the heart, coming nearest to the surface near the second intercostal space at the right border of the sternum. This is the proper place to auscult the aortic semilunar valves. The descending aorta passes to the left of the spine, and the aortic murmur can be heard over the course of both the thoracic and abdominal aorta.

The pulmonary artery, connected with the right ventricle, comes nearest to the surface at the upper part of the second intercostal space at the left of the sternum. By manipulating the stethoscope the exact spot is easily located.

The mitral valve is best ausculted at the apex, and the sound is conveyed to the region of the axilla through a rib.

The tricuspid valves may be ausculted best over the body of the sternum, above the ensiform cartilage.

It is more easily remembered by observing that we listen to the outlet of the ventricles above and to the outlet of the auricles below; or, in other words, we auscult the upper portion of the heart from below, and the lower portion from above the center of the heart.

In the case of the outlet of the ventricles there is another cross—that is, for the left ventricle we listen to the right, and for the right ventricle we listen to the left of the sternum. The reason is apparent when the distribution of the blood vessels is taken into consideration.

When the point of greatest intensity has been located, we ascertain with which sound of the heart the murmur occurs. Following the first sound of the heart, the ventricles are contracting, or in a state of systole; that is, the blood is passing out of the ventricle. Therefore, a murmur heard with greatest intensity at either the aortic or pulmonary areas, must be due to obstruction to the current of blood in its normal direction. If heard with greatest intensity at the mitral, or tricuspid areas, it must be due to leaky valves or regurgitant in character.

Following the second sound of the heart —the ventricles in a state of diastole—the blood is passing into the ventricles. If at the mitral, or tricuspid areas, a murmur is of greatest intensity, there must be an obstruction to the current of blood in its normal direction. If it occurs at the aortic, or pulmonary areas, it must be due to leaky valves or a regurgitant murmur.

The mitral is most often affected. When mitral regurgitation is the form of the lesion, the circulation in the pulmonary capillaries is impeded. Shortness of breath is a prominent symptom. The circulation of the right ventricle is embarrassed, and the ascending vena cava is in a state of passive congestion.

As the hepatic vein empties into the ascending vena cava, it becomes passively congested, and in turn the radicles of the hepatic, the sublobular, and finally the intralobular. The lobular and interlobular are not over-filled by the backset, but contain less blood than normally. On account of the center of the lobule being surcharged with blood in the intralobular vein, it has a dark appearance. The periphery has a lighter appearance. The name nutmeg liver was applied to this condition.

The portal vein receives the blood from the gastro-intestinal canal. The gastric from the stomach, the splenic from the spleen, the superior mesenteric from the small intestines and a portion of the colon, and the inferior mesenteric from the balance of the colon, and through the superior hemorrhoidal branches, from the upper part of the rectum. The middle and inferior hemorrhoidal veins empty into the internal iliac and ascending vena cava. This is the most dependent anastomosis between the portal and general circulation.

Disease of the liver, as cirrhosis, causes passive congestion of the portal system. The effect of passive congestion of the gastric vein is gastric catarrh, and in some cases, hematemesis. The effect of passive congestion of the mesenterics is intestinal catarrh. Diarrhea is present in most cases, but diarrhea may alternate with constipation. The hemorrhoidal veins are surcharged with blood, and hemorrhoids are commonly present.

The effect of passive congestion, due to heart lesion, is the same on the radicles of the portal vein as from cirrhosis of the liver. Passive congestion of the ascending vena cava is always present in case of heart lesion, and the effects are more extensive than from cirrhosis of the liver in not being confined to the portal circulation. The middle and inferior hemorrhoidal veins empty into the internal iliac, a branch of the ascending vena cava, and can not relieve the congested superior hemorrhoidal, a branch of the portal system, as in cirrhosis of the liver, since the ascending vena cava is congested, in heart lesion, the same as the portal vein. This makes it clear why hemorrhoids are more troublesome in valvular lesion than in cirrhosis or other disease of the liver. In every marked case of hemorrhoids, it is advisable to examine the heart.

Around the spinal cord, within the spinal canal, a portion of the space is occupied by the cerebro-spinal fluid, and a portion by the network of veins which empty into the ascending vena cava. In passive congestion of the ascending vena cava, the veins, over-filled with blood, encroach upon the space normally occupied by the cerebro-spinal fluid. The cerebro-spinal fluid is forced into the ventricles at the base of the brain. As the cerebro-spinal fluid fills the ventricles fuller than normal, the cranium being non-elastic, equal space must be made by forcing the blood from the cerebral vessels. This produces a partial anemia of the brain, and has a tendency to produce fainting spells, and even syncope.

Since the renal vein empties into the ascending vena cava, valvular lesion produces passive congestion of the kidneys. The quantity of urine is lessened, and albuminuria is present.

Dropsy, due to heart lesion, begins in the feet. When due to primary renal disease, it appears as a puffiness under the eyes. When due to embarrassed portal circulation alone, as in cirrhosis of the liver, it first appears as ascites.

Clayton Block.

Can Infant's Cry be Heard in Utero?

BY C. A. BUTTON, M. D.,
Holland, N. Y.

I wish to briefly answer Dr. Watts, in June BRIEF, as to his query, by asking: Can the fetus cry before its lungs have been inflated? Of course, asphyxiation would follow breathing in utero.

[Written for the MEDICAL BRIEF.]

The Evolution of Insanity.

BY ROBERT JONES, M. D., M. R. C. P., F. R. C. S.,
Resident Physician and Superintendent, London County Asylum, Claybury; President of the Medico-Psychological Association of Great Britain and Ireland.
London, England.

NO. II.

What do we know about the causation of insanity? We are aware of the fact that heredity plays a most potent part in the transmission of insanity. A history of insanity in the ancestors determines a tendency to this in the descendants. We know, also, that the spread of venereal disease is responsible for increasing certain forms of insanity of a most hopeless character as to recovery, and that overstimulation, in many directions, induced by modern social conditions, contributes to insanity. Especially do we know that intemperance in the use of alcohol is a contributory factor, and statistics collected from many sources, and for a term of years, present an almost unchanged average incidence of insanity through alcohol. And although several antecedents may share in the production of insanity, it is definitely ascertained and agreed that one of the antecedents may be the proximate cause, and may be the direct agent in producing the fully-developed disease. An average of twenty-two per cent of men and ten per cent of women who are insane in London owe their insanity to alcoholic excess.

Attention may be specially called to the diminishing birthrate as further evidence of the love of selfish pleasure, and the shunning of parental responsibility incident upon so-called progress; and not only is there a diminishing birth-rate, but, unconnected with this, marriages are contracted later. In 1901 the birth-rate for England and Wales was 28.5 per 1,000 living, then the lowest rate since the civil register was established, and 1.4 per 1,000 below the mean rate in the ten years immediately preceding. In 1905 this had fallen to 27.6, while for London the rate had fallen to 27.1 per 1,000. This rate has been declining for many years, but never before 1898 had it fallen below 30 per 1,000. Civilization means the association of men and women in towns, which only the rich can circumvent, their wealth enabling them to obtain ready access to the country. City life means artificial desires and their gratification; but civilization also implies progress, which proceeds at the expense of the less fit. A higher standard is fixed, and those who are unable to attain it are left behind to sink lower and lower.

The growth of insanity is undeniably a matter of considerable public importance, and few subjects have of late more employed the pen of every class of critics than the legal curative, custodial, and even the preventive aspects of insanity. Overdrawn and unjust statements have

been made that the insane today are under the care of officials who have neither received the necessary training for conducting scientific investigations, nor have the inclination to pursue them. Medical officers of asylums are stated to be physicians only in name, for they devote neither thought nor time to professional work. The asylum service is held up as a scarcely conceivable career for a young man of promise, or for a person of real capacity. Moreover, it is stated to be a service which has practically excluded insanity from the area of scientific investigation. It is suggested that a special hospital would render unnecessary "the provision of a constantly increasing number of huge buildings for the life-long incarceration of thousands of men and women who are now annually suffered to drift into hopeless incurability," and who accumulate *ex hypothesi* from the failure of asylum physicians to cure them.

Is the treatment of insanity today the shame and reproach which our critics assert? I venture to think that these statements are not only inaccurate, but they are also detrimental to the position we claim to hold in the larger medical world outside our asylums.

To begin with, our present institutions for the care and treatment of the insane are the evolutionary growth of sympathy and unabated humanitarian zeal for curative as well as custodial interests, and it may be truly stated that they are the most up-to-date nursing institutions to be found in any country. Again, we all recognize that diseases of the mind are primarily and essentially an expression of diseases of the body, and that their classification should be based upon general pathology.

The practice of our art depends upon the anatomist, the physiologist, the histologist and the general pathologist, and we share in the knowledge and the discoveries made in the whole field of medicine, and our treatment is that which appertains to all medical men. We claim for ourselves the whole study of medicine, as it forms a part and belongs to the whole profession. Are the biochemical changes in the synapses or the neurones able to explain to us the nature of a mental judgment, or even of epilepsy? Or are those Protean changes described as hysteria definitely ascertained?

Do we know the conditions underlying the nature of delirium as it accompanies pneumonia, hyper-pyrexia, hyperemia and the specific fevers? If the explanation of some of these conditions, which form a part of the domain of general medicine, is at present undiscovered, I hardly think the failure to discover their essential cause lies at our door. I do not say that we ourselves are satisfied with our present results; on the contrary, we desire to attain further improvement, but we are doing our best in the light of our present knowledge. It is not fair to compare our asylums with general hospitals, and to state that in them we only treat symptoms, although in insanity the symptom often transcends in importance the underlying physical abnormality, and when a patient is soothed by remedies fitted to allay the irritability of a diseased brain that remedy is properly administered, and who will venture to say that this treatment of symptoms is empiric or wrong?

The physician who neglects to treat symptoms may be shunning a responsibility which we, as physicians in asylums, are bound to undertake for our patient, who is not responsible for his own acts. We have to see that food is taken when delusions forbid and command otherwise; we have to see that patients are properly clothed who prefer nudity, and that they take exercise when disinclination and restiveness are extreme, as those of us who are continuously familiar with insanity apprehend.

In the Claybury asylum, with a record of 10,945 cases (4,937 males and 6,008 females), the recovery rate for twelve complete years, including 1905, works out at 40.99 per cent of the total admissions (males 37.85 and females 44.28); but early in the last century John Haslam, of Pembroke Hall, Cambridge Apothecary to Bethlem Hospital, relates an experience of 8,874 cases (4,042 males and 4,832 females), and extending over forty-six years in the old Bethlem Hospital at Moorfields, and he states that among his cases of mania 67 per cent recovered. In all the asylums in London for the last year the corresponding recovery rate for cases of mania was only 34 per cent,

whereas in melancholia it fell to 27 per cent. On the other hand, the general death rate among the insane has considerably diminished, and in the quinquennium already referred to the percentage of deaths to the daily average number resident in England and Wales was the lowest recorded for thirty years, viz.: 8.87 per cent.

Having analyzed the recovery rate, and noticed its fall within recent years, let us now compare the varieties of insanity as they are known today with those of which we had knowledge a century ago. Of these, epilepsy appears to have undergone but little change; it is still the intractable neurosis it always was in regard to cure; whilst general paralysis, on the other hand, has become more common. John Haslam was the first to describe this disease, although Esquirol had already noted the extreme gravity of those cases in which dementia was complicated with paralysis. Baillarger remarked in much later times, of this discovery, that it was one of the greatest steps of advancement made in the history of mental disease. It is only fair to suppose, however, that the disease was not then the scourge and the reproach to our treatment that it is today.

In my own experience, for 1905, at Claybury, a proportion of 36.5 per cent of the total deaths were from general paralysis of the insane. The time of onset of general paralysis after syphilitic infection appears also to be shorter than formerly. In a recent average the period is given as about ten years, whereas past records give an average of fifteen years, a fact which tends to show one of two things, viz., either a diminished resistance of the individual to the effects of competition, or an increased "stress" through the conditions of modern life in which the stimuli are both more numerous and more complicated. It is certainly not syphilis alone which is the cause of general paralysis, for in the insane population of the Straits Settlements Dr. W. Gilmore Ellis, a competent observer, states that general paralysis is exceptional there, although syphilis is rampant; probably the Malay race has not reached the stage of evolution in civilization at which "stress" is felt. It is further asserted by those in a position to form a judgment that syphilis is not more common today than it was a century ago, although general paralysis appears to be on the increase. The subtle and lethal effects of syphilis upon the nervous system are a matter of every-day experience, and it may be that the anti-syphilitic treatment of today which has caused the almost complete disappearance of rupial sores, periostitis and necrosis, has, in some manner, at present unknown, so altered the nutritive plasma that the most highly evolved cell (the neuron) reflects its ravages before cells of baser quality become affected. We are able to say fairly definitely that syphilis is an almost constant antecedent of general paralysis, and yet we all say that syphilis is preventable. Why, therefore, not prevented? Whilst conscientious objectors and other faddists make themselves heard, the legislature is silent about infection from this disease, which saps the energy and vitality not only of the actual victim, but also of many innocent descendants.

What did the early physicians know of the condition now so often referred to as "dementia præcox?" Then apparently so rare, but now so common that it attacks prematurely our most promising and educated youth, the brain-worker rather than the manual laborer; but now in young men rather than women, and it is a disease so incurable that it tends to fill our asylums with hopelessly insane patients.

Haslam refers to it as "a species of insanity sometimes occurring about the time of puberty, especially in those who have possessed a good capacity, a lively disposition, and in females more than in males. Their faculties are gradually obliterated until they are at last complete and incurable idiots." Although premature dementia, as such, is not referred to in the Lunacy Commissioners' Report, the statistics for the last quarter of a century support the assertion that it is more common than formerly. These cases almost invariably commence in depression, and it is justifiable to conclude they were classed as melancholia.

Senile insanity, which shows the wreckage due to long-continued stress, has apparently undergone a remarkable increase, partly due, it is acknowledged,

to increased registration. In some districts, senile, or, I would call it pre-senile, insanity, has increased from eleven to twenty per cent of the total admitted into asylums within the last sixteen years.

It is interesting to note that the congenital varieties of mental deficiency show but little increase, according to asylum statistics. These are teratological variations not controlled by any natural laws, and they make themselves apparent by arrest of development often accompanied by physical stigmata. These varieties, which exist in every country, and among every race, are the least reflection upon civilization. They occur among animals, and are familiar to all observers of comparative natural history. In the records of the most barbarous and least civilized of races there occur two forms of psychic anomalies, viz.: the congenital and the toxic, the latter due to some poison, such as occurs from alcohol in our own country, and this latter form has, of late years, aroused much interest, as it is especially one of the preventable varieties.

A hundred years ago practically nothing was known about insanity, and at this time its treatment had been relinquished by the faculty, and fallen into the hands of charlatans. In 1750 a man was described as a conjuror who "cured" insanity. Nevertheless there were able and learned men during this century who interested themselves in mental diseases. The writings of William Perfect, in 1770, described cures from epilepsy, and particularly referred to idleness and gluttony as the causes of insanity—there is a debauchery of inaction as well as of repletion! There are overwhelming statistics today demonstrating that idleness and drink and idleness and insanity are closely connected, and the list of employments of persons of all ranks in asylums supports this view. The writings of Joseph Mason Cox, of Fishponds, in 1804, referred to the mental effects of inebriating potations, and he stated these were due to the circulation of poisons about the head. He called especial attention to the fact that drunken sires were succeeded by insane children.

Alexander Crichton, physician to the Westminster Hospital, London, published, in 1798, two most interesting volumes upon the psychological origin of insanity, and he referred particularly to the effect of the passions in this respect. Thomas Arnold, of Leicester, in 1806, published observations on the nature of insanity. Davis, of Sheffield, translated Pinel's works. John Monro, of Bethlem, and William Battie, also published works about this period, the latter stating that insanity might be cured if the treatment were timely and properly effected. Pargeter, in 1792, offered a classification of insanity, and included in this either maniacal disorders characterized by excitement or those accompanied by collapse. He referred at considerable length to the disturbed emotions as being a cause of insanity, and he named four volumes which, in his opinion, had a most unfavorable influence in causing a mental breakdown, viz.: Wesley's *Journal*, Watt's *Hymns*, the *Pilgrim's Progress* and the *Fiery Furnace of Affliction*, a book the title of which indicates its character. It is especially noteworthy that he describes those who marry, having an hereditary history of insanity, as enemies of their country.

It will be noticed that I have hitherto said little of heredity as a causative factor in insanity. It is not that there is nothing to say. On the contrary, heredity is the most important, as well as the most powerful, antecedent in insanity, but the prominence recently given to this question and the numerous discussions upon "Mendelism" forbid my encroaching further on the reader's patience.

It is certain that permanent progress is a question of breeding quite as much as it is of pedagogy, and of a healthy germ-plasm as much as of training. However much influence the environment may exercise over the individual the nature of the offspring is without doubt and essentially a matter of inheritance. In some of the States of America this question has been boldly met with legislative suggestions, and I confess I feel that in eugenics are to be found the chief remedies for the amelioration of social pathology, but how these are to be applied is a matter of detail. Some are ready with legal restrictions and penal awards, whilst others suggest inculcating prin-

ciples as to the duties to be fulfilled by those who would look for health and healthy families.

The highest function of medical science is the prevention of disease, *i. e.*, the adoption of special measures which are known through experience to be protective against injurious influences; and of all known diseases there is not one in which there is either a greater need of prevention or one which permits of more effectual limitation by precautionary measures when taken in the early stages than insanity. Hence we need statutory authority to treat incipient insanity as other diseases are treated, viz.: with full freedom to the physician and proper and adequate safeguards for the interests of the patient. Such means would prove to be a most valuable auxiliary towards prevention. I am of the opinion that those who undertake the care of the insane in the incipient stages should be especially sanctioned by recognized authority so to do; but I do not believe in public bodies undertaking the care of cases making high payments, as this can be better done by private enterprise and without the "red tape" so dear to public authorities.

In regard to insanity as in other diseases, the neglect of ordinary hygienic rules, and the failure to observe natural laws are inevitably and remorselessly punished. Nature is a good friend, but a bad enemy, for she never forgives a wrong, and she is again wholly selfish—perhaps, more correctly, wholly just—for she invariably decides the race to the swift and the battle to the strong. It is in the observance of a proper health code and by an adherence to temperance in all things, nay temperance in temperance itself, that insanity can best be prevented.

If only the evils of alcohol and venereal disease were disposed of, half the problem of insanity would disappear with them. Many suggestions on the lines of reclamation, education and restriction have been made for fighting intemperance, but hitherto they have not been distinguished for their wisdom or practical statesmanship.

The whole of the so-called "defective class" have a right to be protected against themselves, and the control which they lack should be supplied to them from without; at the same time, society has a right to be protected from the transmission of their defective qualities to future generations. I have no sympathy with the crude and barbarous mutilations proposed by indiscreet and fanatical persons who are devoid of any quality of sympathy or patience necessary to enlightened reform. It is certain that some defectives can be assisted to become in a great measure self-supporting, and it is possible to reinstate others of them in the ranks of the wholly self-sustaining.

It appears to me necessary to subdivide and classify the whole of the defective classes, and if possible to bring them all under one great department of State so that in youth they may be notified and registered, in adolescence be strictly observed, and in maturer years those of them still supervised who have not succeeded in taking their place in the community as contributors to its welfare, and in this way be saved from a life of crime, vice or any of the forms of pauperism. There should be adequate provision for their bodily comforts without extravagance, and such happiness as they are individually capable of, accompanied by a guarantee that society shall not suffer from their defects.

I am of opinion that insanity, which, of all illnesses, inspires terror beyond any other, and causes a sense of helplessness, might be lessened if the hospitals of our cities (whether associated with a medical school or not) were to initiate out-patient departments, where patients could apply for advice and submit to treatment for mental symptoms without loss of liberty. Where this experiment has been tried it has proved most satisfactory. Moreover, our public asylums, built and supported by rate-payers, should give them some relief and benefit in return. They should be the centers for disseminating, through their medical officers and nurses as missioners, a health-conscience and a creed which should reform the districts they serve. Each of our asylums should be a center for clinical instruction. It should be a school where any qualified medical practitioner could refresh his knowledge of the subject of insanity in all its bearings, and where the medical staff should

give advice to any applicant suffering from premonitory symptoms of incipient insanity, and power should be given by law to take such cases in for treatment, if necessary, as voluntary boarders.

An asylum should be the place where the principles of eugenics should be widely disseminated, for surely it is wiser and better to make every effort to arrest insanity before it has reached the stage of certificates, than to wait until it has been legally established. The law of the land empowers the medical man to deprive his fellow-citizen of his liberty; and upon a written statement a citizen may be incarcerated until he can show that he is entitled to his restoration. To no other subject in the State is a similar power given to dispossess an individual of his liberty, to disfranchise him, to alter his position towards his friends, and his responsibility to the law, and so to disturb his social relations that the greatest distress is caused to his relatives. Surely this power imposes upon the medical man the duty of being acquainted with his work, and every facility should be given by public bodies for students and medical men to receive full and adequate clinical and systematic instruction in insanity. It is for this reason that I would strongly support the proposed scheme for the establishment of "reception houses," although I think that the erection of an acute mental hospital within the grounds of the asylum is a most excellent and admirable proposal, and one which is expected to yield the most beneficial results.

[Written for the MEDICAL BRIEF.]

The Choice of Treatment for Fibromyoma of the Uterus.

BY J. INGLIS PARSONS, M. D., M. R. C. P., M. R. C. S.,

Surgeon to the Chelsea Hospital for Women. London, England.

The great variety in the size, situation and symptoms produced by these tumors, together with the difference in age, general health and social position of the patients, make the choice of treatment a difficult problem, and one requiring much judgment and experience.

In order to discuss the question adequately, I propose to consider the cases under seven different groups:

Group 1.—Cases which present no symptoms, and are discovered accidentally.—Under these conditions no operation is permissible, but the patient should be told of her condition, and warned that the tumors may give trouble if the growth continues. As far as it is possible, hygienic measures should be advised, and medicine be given to prevent any increase in growth. Since the tumors are found chiefly in women who have not had children, or have gone a long period without a child, it is possible they are partly the result of a baffled desire on the part of the sexual organs to reproduce the species. On this basis I advise measures to restrict the activity of the ovaries. No simulants should be allowed, the meat diet is reduced to a minimum, saline aperients are taken regularly to reduce the congestion of the pelvic organs, and bromide of potassium is given for four or five days before and after the menstruation, when the activity of the sexual organs is at its maximum. The patient is advised to avoid all erotic literature and conversation, and occupy her mind with some practical object in life, and to take regular physical exercise in the fresh air.

In thyroid extract we have a drug which appears to have direct influence in some patients over the growth of the fibromyoma.

The notes of the following case bear this out: A nurse, aged forty-two; single woman, came to me in July, 1903, complaining of nausea, severe pain in the pelvis, walking or standing; much worse during menstruation. The bladder was irritable, caused frequent micturition, and pain on defecation. Menstruation was regular, and the loss normal, less than year ago. She was thin, pale and delicate. On examination the uterus was found enlarged by fibromata. The fundus reached within two inches of the umbilicus. There was much distortion of the uterus; the cervix being twisted round and upwards to the left, almost out of reach, making electrical treatment impossible. She refused operation and preferred to try medicinal treatment. I gave her thyroid extract and iron between men-

struation, and during the period ergotin and ammonium bromide. In six months she had improved greatly. The pains and nausea had gone; she had put on weight and color, and could do her work with comfort, while the tumor had decreased and was five inches from the umbilicus.

We must draw a distinction between private and hospital patients. The latter can not afford to be long away from work, or spare the time necessary for a course of electricity, so that when medicines fail operation becomes necessary. With private patients it is different.

Group 2.—Moderate enlargement of the uterus by fibromyoma, with severe menorrhagia, but without pressure symptoms, although the patient may complain of pains.—Under these conditions, if the hemorrhage and pain can be abolished, the patient is restored to health. Since the female pelvis and abdomen have been designed to accommodate the enlarged uterus of pregnancy, it is not the size of the uterus and tumors that cause the symptoms, or we should never come across patients with tumors, but without symptoms.

Thyroid extract may be tried for these cases. To control the hemorrhage large doses of ergot may be given, but it rarely does much good. Chloride of calcium may also be tried during menstruation in doses of thirty grains, three or four times a day. It acts by increasing the coagulability of the blood. Viburnum prunifolium sometimes helps, as does suprarenal extract.

When the treatment already described has been tried and failed, we have two resources left. The use of the constant current after Apostoli's method, or operation. Each has its defects, but the balance between the two has altered of late years, owing to the reduction in mortality from operation.

The advantages of electricity are these: It is practically free from risk, when blunt electrodes are used, and no puncturing is done. I have been using it for fifteen years, and never lost a patient. It stops the hemorrhage, and takes away the pains in ninety-five per cent of this class of cases. No anesthetic and no nursing home are required, so, for private patients it is less expensive than an operation, and the patient still retains her sexual functions. In addition to this, it improves the patient's digestion, and they put on weight. It also helps to cure any constipation that may be present; a patient under my treatment went up from five stone to seven stone in three months.

Its disadvantages are that it takes up a great deal of the surgeon's time, compared to an operation, and the remuneration is much less. It is tedious to the patient, and does not remove her tumors, although it stops the growth and abolishes the symptoms for two or three years, and in many cases does so permanently.

To take the other side, the risk of the operation in this class is very small, but is still more than with electricity. An operation is more expensive to the patient and much less trouble to the surgeon. At the end of a few weeks it is done with, and over, although the patient may take some months to get strong. It gets rid of the tumors, and prevents further trouble, but at the expense of the patient's sexual functions, since the menopause comes on in a few years, even when the ovaries are left behind. Operation has this drawback, that it may be followed by a neutral hernia or adhesion of intestine to the stump or abdominal cicatrix.

It may be urged that the percentage of successes by electricity is placed too high. I can speak only from my own experience. In cases coming under this category the hemorrhage can be stopped in at least ninety-five per cent.

One of the reasons why failure with electricity takes place is that the surgeon expects improvement to come too soon. In half the cases there is no improvement in the hemorrhage until the treatment is nearly, or quite finished. There may even be an increase in the loss at first, but the pains begin to go away sooner.

In November, 1900, I had a patient aged thirty-eight, who, for over a year, had profuse loss, increasing every month. Menstruation went on for fourteen days, and she required eighty diapers. There was great tenderness and pain in the pelvis, with profound anemia. On examination the uterus was found uniformly enlarged with fibroids, and reached within one and a half inches of the umbilicus.

The sound passed four and a half inches. Thirty applications were given; improvement set in only after the treatment was finished. The pains disappeared, the hemorrhage was reduced to normal, and the patient has been quite regular since. This is one out of many cases.

Another point to be remembered is this: Many women are most anxious to become mothers. With one or two small fibromata in the body of the uterus there is nothing to prevent conception when the hemorrhage has stopped, and although many of the patients are sterile, a fair proportion become pregnant, and have living children in spite of the tumors. So desirable a result is always possible after electricity, but is impossible after hysterectomy.

In one of my earlier papers I demonstrated by experiment the fact that there is no molecular disintegration between the poles of a constant current, and, therefore, we must not expect the tumors to disappear; this prediction has been since verified in practice. Many neglect to use a treatment which is of great value, and will do what nothing else can do.

When it is impossible to apply electricity, a fair trial should be given to curetting. The improvement from this in reducing hemorrhage often lasts for six months. Some patients who are anxious to have children prefer to have this done several times rather than face hysterectomy, unless urgently called for. When curetting fails and electricity can not be used, we have still two operations before us, hysterectomy, or removal of the appendages. The former is the operation for choice, while the ovaries are left behind, but it sometimes happens that a patient's strength is so much reduced that the minor operation offers the best chance of life. In this group, with only a slight enlargement in the size of the uterus, there is no difficulty in completely removing both appendages. Or it may happen, as it once did to me, that the patient takes the anesthetic very badly. Only last year I began an abdominal section with a view to hysterectomy, when the patient's pulse and respiration showed signs of failure, probably due to extreme anemia; by the injection of strychnine and other measures, she rallied sufficiently for me to remove the appendages. She is now well, and has not menstruated again.

In my experience, the results from this operation have been successful when the appendages have been completely and not partially removed.

Group 3.—Small tumors producing pressure symptoms without menorrhagia.—When the bladder in these cases is affected, I find that electricity does not cure it. Why, I do not know.

If the pressure is on the bowel, with small tumors in the body, it can only be produced by retroversion. After the uterus is restored to its place, a Hodge pessary can usually be found to keep it there, and electricity can be used to restrain the growth of the tumors and take away the pains and tenderness. The only successful remedy for a bad case of pressure on the bladder is hysterectomy.

Or it may be that pressure symptoms are caused by the projection of a single sub-peritoneal fibroid without much enlargement of the uterus. The proper operation then, if it can be carried out, is a myomectomy. On January 3, 1903, I saw in consultation a lady, aged twenty-three, who suffered from intermittent pains in the abdomen, and pelvis aggravated by menstruation or active exercise. A single subperitoneal fibroid was found, and removed, leaving the uterus and ovaries intact. She made a rapid recovery, and has been in good health since.

Group 4.—General enlargement with pains and hemorrhage resembling the enlargement up to the fifth or sixth month of pregnancy.—The value of electricity and curetting appear to diminish as the tumors increase in size. In regard to the former, it can easily be understood that a current of one hundred M. A., passing through a tumor of one pound in weight, will have a quarter the effect when passed through a tumor weighing four pounds. There is also more likelihood of a distorted uterine canal and cavity, and difficulty in applying the electrode properly. For the same reason curetting can not often be thoroughly carried out.

In 1896 I saw a case of general enlargement of this kind on account of profuse menorrhagia. She was thirty-six years of age, and had two children, and was so weak from hemorrhage she could not

stand. I stopped the loss completely for five years, and she felt very well, and the tumor was most distinctly diminished in size, but the edema of the ankles never went away completely. In 1901 she had hemorrhage from the bowel, produced, I believe, by the pressure of the tumor above. This also was stopped by electricity. Since then she has kept well. Although this patient has been well for six years, she has not attained the permanent relief from electrical treatment which has so often followed in cases that come under Group No. 2. As the mortality from hysterectomy is so much reduced, I should advise operation for this group, and if this were refused I should try electricity.

There can be no doubt of the advantage of hysterectomy in this group over removal of the appendages. In the first place, the size of the tumor draws the appendages up, and puts them on the stretch, so that it is difficult to remove them completely, and unless this is done, the operation fails. Even when it succeeds, the tumor left behind is liable to sag about the pelvis and cause discomfort.

Group 5.—Tumors forming a round mass, nearly filling the pelvis, and sometimes impacted.—For these cases hysterectomy is the best treatment, and the sooner it is done the better, for we may arrive at a point where, from pressure on the bowel, ureters or bladder, the patient's condition rapidly deteriorates, and with it the resisting power necessary to withstand the shock of the operation.

Impaction, as a rule, is due to the tumor projecting under the sacral prominence. When it grows under and distends the broad ligament, we may have a most serious operation. In a recent case I found a large tumor filling the pelvis, and extending above the pubes to the umbilicus, while the uterus, normal in size, was on the left, and jammed up against the pelvic wall. The bladder was separated from the uterus, intimately adherent in front, and a piece of it was removed with the tumor. The opening was carefully sewn up, and the bladder drained. The large oozing space left in the broad ligament after removal of the tumor was treated by hot sponges, and then laced together with silk. Beyond symptoms of shock, she made an excellent recovery, and she is now well and free from symptoms.

Group 6.—Very large tumors, more or less filling the abdomen.—On account of the size of these tumors it is better to operate than apply electricity. Although the latter will take away the pains and stop the hemorrhage, it does not restrain the growth of the tumors enough, and after two years has to be repeated. Another point is that the patient may be a single woman, to whom the swelling of the abdomen is a serious drawback. The slight amount of shrinking in large tumors from the application of electricity is not sufficient to alter the general appearance. On the other hand, the removal of one of these large tumors with numerous adhesions, entails considerable risk. We must also remember that the growth of fibromyoma is much slower than that of an ovarian cyst, and is by no means progressive. Having attained a certain size, they sometimes remain stationary, and in a few cases may show signs of retrogression.

In November, 1896, a patient came to me with a large fibromyoma filling the abdomen, and reaching to the ribs. I advised operation, which she refused. Electricity was tried. The pains and menorrhagia were stopped, and for two years she was able to do her work as a dressmaker. 1898 the treatment was repeated. She has kept well since; has had no return of the pains or menorrhagia. I saw her recently, and the menopause appears to be coming on, but the tumor is bigger, and may have to be removed. It is remarkable that this patient should have kept so well for eight years, considering the large size the tumor had attained before she came for treatment. It emphasizes what I stated before that the female pelvis and abdomen are very tolerant of a mass inside them, if it resembles in shape the pregnant uterus.

The difficulties found in operating on these cases are sometimes great. For instance, in one case the rectum and part of the sigmoid flexure were drawn up and intimately adherent to the back of a large fibrocystic tumor, which I removed. It was impossible to strip it off. I had to leave a portion of the capsule attached to the bowel, and get the tumor away as I

best could. There was not enough peritoneum left to cover in the floor of the pelvis. The patient recovered in spite of these drawbacks, and is now well.

Group 7.—The relation of the menopause to fibroids.—There are two points for consideration:

(1) Is the menopause delayed beyond the usual age?

(2) Do the tumors cease to grow or shrink after the menopause?

If a patient comes to us over the age of forty, and her sufferings are not great, she might prefer to go on bearing them if she knew that there would be a cessation in a few years rather than run the risk of hysterectomy.

My experience shows that the menopause is nearly always delayed, and in many cases for as much as five to seven years. This applies particularly to the fibromata with menorrhagia, so that a patient of, say forty-two, may expect another ten years of trouble unless something is done to relieve her.

Supposing the patient is, say fifty years old, will the tumor continue to grow after the menopause? So far as my experience goes, I should say that the number of cases is small where the growth goes on, and is certainly not more than five per cent, if as much.

I find the amount of diminution from the menopause varies much, sometimes amounting to one-half, and in other cases to one-third. It is less in proportion in the case of big tumors, and also in very hard, old-standing tumors having a large proportion of fibrous tissue.

I have been able to trace three cases of fibromyoma treated by electricity which have gone through the menopause:

Case 1.—In 1888 I treated a governess, aged forty-four, at the hospital. The uterus was enlarged, hard and nodular, and reached within two inches of the umbilicus. Menstruation was profuse; lasting fourteen days, and had caused so much anemia that she was unable to earn her living. The uterine canal was distorted, and it was difficult to pass the electrode. Thirty applications were given, and a course of iron at the same time. By March, 1889, she was regular, using only eight diapers. March, 1890, keeping very well. November, 1893, is sometimes irregular, but never loses much; feeling very well. August, 1896, has seen nothing for fifteen months. Age fifty-five. The tumor is much smaller, and can hardly be felt above the pubes. This patient, who came for treatment at forty-four, still had ten years of menstruation before her.

Case 2.—In 1891, a woman aged thirty-five complained of profuse menstruation, which began four years previously. She was anemic. The uterus was found to be enlarged, hard and nodular, and reached to midway between the pubes and the umbilicus. Fourteen applications were given, and the hemorrhage reduced one-half, and her pains disappeared. She kept well for two years. In 1893 the tumor showed signs of growing; eleven applications were given. She kept well for five years, then the tumor began to grow again. In 1899 it reached the umbilicus, and she began to lose more. I saw her in June, 1904, she had seen nothing for eight months; felt well; free from pain. Tumor about the size it was before menopause came on.

Case 3.—A married woman, aged forty-one, was seen by me in 1896, on account of pain and swelling in the abdomen and profuse loss during menstruation. The uterus was hard, nodular and enlarged, and reached within three inches of the umbilicus. Thirty-three applications were given, and the loss reduced to normal. The pains disappeared, and the tumor was reduced in size by one inch. She kept well for two years, when the pains returned, so nine more applications were given. For the next six years she kept well. I saw her in October, 1904; menstruation had then ceased for six months. She was looking well; was free from pain and other symptoms. The tumor, on examination, was found to be reduced in size by one-half.

Inclosed find one dollar for the BRIEF, which makes about twenty-three or -four dollars that I have paid for the BRIEF, for I have been a constant subscriber since 1882, and I like the BRIEF.—B. F. GREEN, M. D., Bloom, Ky.

[Written for the MEDICAL BRIEF.]

Opium Eating and Smoking.

BY DONALD MACLAREN, M. A., M. D.,
London, England.

NO. I.

Some years ago I had the privilege of hearing a paper on Opium, read by the late Surgeon-General Sir William Moore, K. C. I. E., at the Imperial Institute, London. I was subsequently fortunate enough to obtain a copy of the address, and as it is but little known, I have ventured to make an abstract of it, feeling assured that it will prove of interest to the readers of THE MEDICAL BRIEF. It is, perhaps, hardly necessary for me to say that Sir William Moore spent the greater part of his life in India, and was universally regarded as the great authority on everything appertaining to drugs and medicines in that country. I have not slavishly adhered to the original paper, which is of considerable length, but have extracted those portions which, at the present time, seem to be of the greatest value to students of this important subject. In some few instances I have ventured to modify the phraseology adopted, so as to bring it in accord with modern nomenclature. This has been especially the case in the spelling of the names of the active principles contained in the drug. These alterations, however, are few; nothing of importance has been added, and the spirit of the paper has been scrupulously maintained throughout.

Opium is the juice which exudes from incisions made in the head or capsule of the poppy. But this juice is a very complex substance, and different samples vary in composition. The most important constituents are morphine, codeine, anarcotine and thebaine. Morphine and codeine in medicinal doses, are narcotic, while anarcotine possesses considerable antiperiodic powers, or powers like quinine, against periodical fevers, such as ague. Thebaine is a tetanizer, and belongs to the same pharmacological group as strychnine and brucine.

Opium, if taken in sufficient quantity, is deleterious; but this is not the use, it is the abuse, of opium—a remark which is applicable to other things. A person may feel altogether better for a glass or two of wine, and altogether worse for excess. Even a baby may have, and often does have, too much of that harmless fluid, milk, which makes it sick, while it thrives on a smaller quantity. Tea is a fruitful source of dyspepsia and of "nerves," if taken in large quantities or wrongly prepared. So is tobacco. Even rice is a fruitful cause of bowel complaint, if eaten too new. In short, what source of enjoyment is there—nay! what necessary of life—which, though in moderation, harmless or beneficial, is not hurtful in excess? But opium is not only deleterious but also poisonous, if taken in sufficient quantity. As De Quincey observed: "If you take a good deal of it, you must do what is disagreeable to any person of regular habit, viz., die." But many other things which we use contain poisons; tea, tobacco and coffee, for instances. Now, this reminds me of a paragraph in a provincial paper which illustrates the ignorance prevailing with reference to opium. In some papers on the subject I observed that opium, used moderately, was not more poisonous than several other things. The editor said, they were perfectly surprised at Sir William Moore's statement, and triumphantly added, opium not poisonous! Why, an inquest was held last week on a child who died from an overdose of opium.

It is not, however, only about opium that dense ignorance prevails as regards Indian matters. A Bristol divine told his hearers at a meeting in support of Indian missions, that a Zenana (the female quarters of a residence) was a kind of bazaar, and that the unwearied missionaries spent a large proportion of their time within its precincts prosecuting the good work. As ridiculous as if he had said that clergymen in this country lived chiefly in ladies' chambers. At Salford, at a missionary meeting, a reverend gentleman is reported as essaying to describe the manners and customs of the Indians. He said there are social distinctions which are called caste, and one caste will never speak to the other (which is quite untrue). The low-caste men are known as coolies, and their women folk as sweepers, because they are employed to sweep the streets, which again is false. The morality of these people, both men and

women, may be judged from the fact that they go about with their feet and legs bare. Well, so do numerous Scotch girls. Many of the higher class women, the speaker said, may be seen bathing in the tanks, or *talookas*, as they are called. A taluka not being a tank, but a small district. Again this keen observer of Indian life informed his hearers that high-caste native ladies are very chary of showing their faces, and for this purpose they use a large fan called a punkah—as ridiculous as to assert that European ladies use a window-curtain instead of a fan. Those accquainted with India will at once see that either this reverend gentleman was very ignorant, or intentionally deceptive. As with other things, so with opium. The desire for some stimulant always has been a characteristic of humanity. In the earliest times Noah planted a vineyard, and our Lord did not disdain wine. There is little doubt that the *nepenthe* of Homer was hemp, and that when bright Helen mixed the "mirth-inspiring bowl," some part of the hemp plant, "so friendly to the joys of life," was used by the fair compoundress.

From Juvenal, Perseus, and other old writers, we know that men in their time did not live without stimulants. The natives of the South Sea Islands not only ferment the milk of the cocoanut, but have their *ava* or *kava* prepared in a disgusting manner, which need not be particularized. A compound of like nature has been described as used in Tibet. The Englishman drinks gin, beer, port or porter; or, happily, a good many now claret; the German takes beer; the Frenchman absinthe; the Scotchman whisky; the Irishman ether. There is also the morphinomaine, which, it is stated, murders numbers of Parisians.

The tribes of the Central Asian steppes, and the wanderers on the Himalayan slopes, and Easterns generally, finding opium handy to pack and carry, and obtainable economically, being the produce of the adjacent plains, take this form of stimulant. So do Turks, Persians, Arabians, Slavs, Albanians, not a few Greeks, Malays, Hindoos and Chinese. And, what is more, many of these nationalities have been addicted to the use of opium for centuries past.

The reasons why eastern people so generally use opium are various. First, it is a product of eastern lands, as Persia, Turkey and China. Second, the ban placed on spirits by eastern religions must be regarded as a cause. Third, malarious fevers prevail mostly in eastern countries, and opium, since the days of Pliny, has been regarded as a prophylactic against such maladies; and is, indeed, used as such by residents in the fen districts of this country. Fourth, eastern nations are generally less energetic than inhabitants of a colder clime, are more indolently inclined, and opium is just the agent to administer to such attributes. Fifth, a more or less vegetable diet is usual, and often there is scarcity of food. Opium enables people to do with less food than they would otherwise require; the same may be said of tea, as used by many poor people in this country. Last, opium is cheaper than wine or spirits.

Although the use of opium in India dates from time immemorial, the Mahomedan invasions, and the spread of Islamism in India gave great impetus to the habit of using opium. The use of wines and spirits being prohibited, the Mahomedans, finding opium a product of the country, took kindly to the habit. But there are also other reasons for the permanency of the habit. Numbers are born of ill-nourished parents, they work hard under a tropical sun, and they live on meager diet. And this is not so much the result of want of means—for the Indian peasantry were never so prosperous as they are now—but it is the result of climate, habit, custom, food and religious observances. Many, as a consequence of their manner of life, are latently, if not patently, scorbutic, and they are so prone to bowel affections that diarrhea has been called *morbus bengalensis*. They are still more prone to *tup* or *bukkar* (fever), a fever which often does not resemble any of the types described in medical text-books, but is the same character of fever as the fever of prolonged over-exertion, written of by Dr. Knott, of Dublin, or the fatigue fever of Mons. Peter. Again, the working classes of India have few means of recreation. They have not, as working men in England have, theaters, music halls, free libraries, lecture rooms, clubs, parks and gin

palaces. The Indian laboror has one creative comfort—the pipe. It is these conditions, climatic, dietetic, social and country produce which impels to the use of opium, as almost a necessary of life. As a recent writer observes:

"The inhabitants of eastern countries live under conditions of life special and peculiar to them; conditions of climate, race, etc., of which we have no experience whatever. Now for any set of men in Britain to argue that this or that is not needed in India or China because it is not needed in England, seems a very irrational proceeding. This is precisely what the anti-opiumists are doing. How can they pretend to know what a Hindu or a Chinaman does or does not require in the way of a sedative? It is a race question entirely. Anti-opiumists always have the opium-smoking den of East London or New York in their mind's eye. This is about as rational as if a Hindu argued about the alcohol consumption of decent middle-class people in England from reports of the squalor and misery seen around the gin shops of a Liverpool slum."

It is often asked why Europeans in the tropics did not usually take to smoking opium. Now, an European, from his youth upwards, has been in the habit of seeing wine and spirits used, as an Indian from his youth upwards has been in the habit of seeing opium used. And it is a characteristic of Europeans, and especially of Britons, to pursue their habits and customs in whatever country or climate they may be resident. Moreover, smoking opium takes too much time, and is a troublesome business, requiring a pipe, a lamp and instruments to manipulate the opium, or, rather, *chandul* with. For it is not crude opium which is smoked, but a preparation of opium called *chandul*, or *chandoo*, which is a decoction of opium of about the consistence of very thick treacle, and which, for the purpose of sale and smoking, is poured into little china bowls. When a customer comes into an opium shop, he takes a bowl of *chandul*, an iron wire or spoon, and a pipe, and finding a vacant space, reclines on his elbow to smoke. There are two kinds of pipes used. One, the best imported from China, and costing about four rupees. The stem is a hollow tube about a foot and a half long, having fixed on the side nearly at the end opposite the mouthpiece a porcelain bowl. This is conical in shape, the base of the cone being external, and the apex fitting into the pipe-stem. But the base of the cone is closed, excepting a very small orifice in the center. The Bombay-made article, which is used in the greatest numbers, is altogether an inferior implement. There is a straight wooden stem, to the end of which, or to the side of which, is fixed a small porcelain receptacle perforated by a small hole in the base.

Between every two persons there is a small lamp burning. The smoker dips the end of his iron wire, which is flattened like a spoon, into his bowl of *chandul*, and, by twisting it around, causes a small mass of *chandul* the size of a large pea to adhere. This he inserts into, or rather over, the small aperture in the bowl of the pipe described above. Then, putting the end of the pipe-stem into his mouth, he applies the *chandul* to the flame of the lamp. The *chandul* burns and frizzles, and while the *chandul* burns the smoke is drawn up. The morsel of *chandul* is thus disposed of in a few whiffs. There are six or eight smokes in a bowl, and the price varies from four pies to an anna or more, according to the size of a bowl.

Sir William Moore has some personal experience of opium smoking, and says: "Being desirous of accommodating myself to circumstances, and on the principle *flat experimentum in corpore vili*, after considerable trouble in finding a clean pipe, I essayed the process, and had a pretty good dose of *chandul* smoke (which I have often since repeated). But it had no more effect on me than if I had smoked so much chopped hay or tea leaves." He continues:

The anti-opiumists make a great point of the fact that Chinamen, when they smoke opium, lie down to do it, and John Bull is called upon to believe in the terrible power of a stimulant or narcotic (for opium is both, according to the amount taken) which cannot be imbibed standing or sitting. But *chandul* may be smoked sitting or standing, as well as in any other posture. To smoke sitting, however, would require a chair and a table for the

lamp, for which there would not be room in opium houses. The most convenient manner of smoking is to recline, supported by the elbow, and it is convenience, custom, and the fact that poor natives do not use chairs or tables, nor possess them, which has led to the practice of lying down to smoke, and *not* the overpowering nature of the agent. It may be recollected that it was the custom of the Romans to recline at their banquets.

Sir George Birdwood holds *chandul*-smoking to be a strictly harmless indulgence, and he attributes this to chemical changes which the opium undergoes in the combustion when smoked, by which much of the narcotic principles of the opium are destroyed. I fully agree with Sir George Birdwood that the habitual smoking of *chandul* in moderation is not deleterious, and I also say that in many instances it is beneficial. But as everything in this world has a drawback, so *chandul* may be used to excess, when the reverse is the case. And unfortunately, as with liquor, so with opium, there are people who can not refrain from taking more than does them good.

But opium is prepared and smoked in quite a different manner. The opium thus prepared has several names, one of which, very commonly used, is *muddut*. The word *muddut* in the vernacular means "help," "aid," "assistance," and the very name itself may be in some degree accepted as an index of what the natives think of this manner of using opium. *Muddut* is prepared from *chandul* and dried bran. Small balls of it are smoked from the native pipe, known as the "hubble-bubble." As no lamp is used, there is no greater convenience from lying than from sitting, so *muddut* is usually smoked in the latter posture. Contrary to what is seen at a *chandul* house, some at the *muddut* house smoke outside the shop. The explanation has been partly given in the posture for smoking adopted; but another reason is that the smoke from the *muddut* pipe is more dense, and would be more irritating in a confined space. If bran can not be obtained, or when people are very poor, they use cow-dung to mix with the opium. Cow-dung, as all Anglo-Indians know, is extensively used by natives for fuel, as, when dry, it burns very readily.

The worst and most deleterious preparation of opium for smoking is known as tye-chandoo, and is composed of the refuse of opium pipes, the refuse of opium gungah or bhang, and bad tobacco. Tobacco smokers know the difference between good, bad or adulterated tobacco. And respecting wine and spirits, as the wine merchant said on his death-bed, as the best advice he could give to his son: "Remember, my son, wine is made of everything; sometimes, even of grapes." So it is with opium, which is often credited with injurious effects which should be attributed to adulteration. The advice the lamented Sir Andrew Clark gave to a patient, viz.: "Well, if you must drink, drink only the very best wine," is applicable to the use of opium.

Many people do not smoke, but take opium in the shape of *umal-pawnee*, or opium water, which is a solution of opium in water. Others consume the crude opium, usually in the form of pills. This is the most injurious manner of using opium. For when crude opium is taken all the active principles are introduced into the stomach. Opium taken into the stomach lessens both secretions and movements of that organ, and so checks digestion. The opium has to be digested and absorbed before it passes into the system. And there is not the destructive agency of fire, as when it is smoked. Opium is also taken in the form of sweetmeats, and it is sometimes mixed with *charus*, the wax of the *cannabis indica* plant, or with *majun*, an electuary made of charus and spices. Some persons smoke the native *beeree*, or cigarette, which is composed of a small quantity of tobacco wrapped round with plantain leaf, and which may be previously soaked in opium water.

We are told that using opium is wicked, immoral and destructive to health. I have often smoked opium, and I really do not see where the wickedness and immorality come in. Morals, however, differ in different countries. What would be considered immoral in countries where opium is used (the European dance, for instance), does not seem to be so considered in this country.

[Written for the MEDICAL BRIEF.]

Puerperal Insanity.

BY GERSHOM HYDE HILL, A. M., M. D.,

Professor of Mental Diseases in the Drake University College of Medicine. Des Moines, Iowa; Superintendent of "The Retreat" for Nervous and Mental Cases, etc. Des Moines, Iowa.

Mental derangement has, for a long time, been called puerperal insanity, if it appears within six weeks after childbirth, and if confinement seems to be the exciting cause of the trouble.

Etiology.—Instability in the nervous system, and an inherited tendency toward mental alienation, are a predisposing cause to this, as well as to other forms of insanity. Anxiety at the time of labor, and disappointment concerning the outcome, may cause the mind to wander from its moorings; the presence of company in the bed-chamber, or mental disturbance caused in any other manner, may produce a profound effect upon the patient, since the mind is often in a weak and susceptible condition immediately after labor. This is illustrated by unusual irritability in the disposition of lower animals, which are watching over new-born offspring. Inability to secure needed rest and sleep and composure of mind after labor may cause the mental faculties to give way. If the infant is not welcomed by mother or relatives; if mother and child are not suitably and sufficiently cared for at this critical time; if extreme anxiety worries the mind of the mother as to the future welfare of herself or of her child, such conditions may cause the mind to wander.

The physical causes of puerperal insanity are prolonged, painful and exhausting labor; great loss of blood, infection of blood by retained placenta, or any other condition producing sepsis.

Pathology.—There is seldom any gross lesion of the brain or any particular disease in the organ of the mind to produce this sort of derangement. Puerperal insanity is of the functional sort, due either to a neurasthenic condition or an anemic condition of the brain, or to a septic condition of the blood.

Symptoms.—These may be the manifestations of a despondent and hopeless mind, like those which characterize melancholia, or the patient may be excitable and talkative and restless; flighty, exhibiting a mild delirium, and revealing transitory delusions or hallucinations, such as we see in cases of mania; or, in the third place, the variation of the mind from its normal standard may be by dullness, apathy, languor, indifference, lack of interest in self or child or environment, amounting, in some cases, to complete stupidity and sheer listlessness concerning evacuations. Such a case of puerperal insanity would be like one of dementia.

Delirium is seldom a symptom of insanity, but this condition of the mind usually indicates a toxic condition of the blood, and is likely to produce the form of insanity which we call puerperal mania; an anemic condition, or an exhausted condition, of the body is more likely to develop into melancholia or dementia.

Diagnosis.—The fact that the mind of the patient is affected will be readily recognized by the physician if the derangement occurs at the time of labor or immediately afterward, before he is discharged, but if the after-care of the patient is insufficient, or improper, or given by ignorant or superstitious persons, and if the wandering of the mental faculties is insidious in its manifestation, and if the patient is suffering from bodily weakness, or if there is, in fact, something serious to worry about, the impaired condition of the mind in a puerperal case may run along for days and weeks without being appreciated, and without receiving proper attention. If the condition is despondency, it will very properly be charged up to physical weakness, so the fact that it amounts to insanity will not be realized by relatives. Even if the patient is somewhat disorderly, it is hoped and expected that the trouble will disappear soon as the patient gets stronger, physically. If there is present the carelessness of dementia, the mental condition is also charged up to physical weakness, and is expected to soon disappear.

Prognosis.—Since puerperal insanity is, for the most part, a functional disorder, and since, in many instances, there seems to be an adequate exciting cause for the derangement, these cases may be regarded as acute, and curable. Most of them, if

fairly well managed at home, under the direction and medication of the attending physician, will, in a few weeks, or a few months, be completely restored to health, and to a normal condition of mind.

Treatment.—In this disease, like any other, the first indication is to remove the cause of the trouble. The patient must be well-nursed, in a quiet place; preferably by an experienced and judicious person who is not a relative. The child must be weaned, and kept apart from the mother, as far as practicable. The vagina and uterus must be kept clean, and in an aseptic condition; the rectum must be emptied daily; great pains must be taken to have the patient well-nourished with simple, nutritious, easily-digested food. Oftentimes it will be impracticable to administer anything except liquid diet. An abundance of sleep at regular intervals must be secured, and a wholesome influence exercised over the mind of the patient. When a normal condition of the body has returned, then exercise in the open air, diversion of the attention, a resuming of domestic duties, gradually and moderately, should be undertaken.

Such persons are steadied and greatly encouraged by having a nurse who will serve as a co-laborer and companion until the patient is fully capable of taking charge of the affairs of her own household.

If the facilities at home are altogether inadequate and unsuitable; if the husband can not afford to pay the attending physician for frequent visits and the wages of a suitable nurse, then it may be necessary to place such a case of puerperal insanity in a State hospital for treatment, although the patient would recover at home, in a few months, if properly cared for. Women who are strongly predisposed to insanity, and when the puerperal condition is simply "the last straw which breaks the camel's back," or when the physical condition, if bad, and when the cause of insanity, which develops at the time, or soon after the child is born, is of such a nature that it can not be removed, then the prognosis is unfavorable, and the mental derangement is likely to prove permanent.

Equitable Building.

[Written for the MEDICAL BRIEF.]

Some Later Views on Tuberculosis.

BY SOLON R. TOWNE, A. M., M. D.,
Professor of Hygiene and State Medicine in the University of Nebraska.
Omaha, Neb.

Sanatorium methods of pure air, selected food and prescribed exercise are a success in the treatment of tuberculosis, provided the patient is reached sufficiently early in the history of the disease, so that an early diagnosis becomes very essential in the control of tuberculosis and its cure. The physician must be the educator of the general public in methods necessary for the control of such a prevalent disease, and a part of his effort at education must be to let the public know how essential is early diagnosis. He must also inform himself as to the most delicate methods which are required to establish an early diagnosis. This, for himself or the public, is to be no easy task. A patient who is, as he thinks, only a little weaker than usual, or a little bit off his appetite, possibly a little short breathed after exercise, is in a condition which, if it be due to beginning tuberculosis, will require much skill to convince him of the gravity of the situation. If you could show him the tuberculous organism under the microscope as coming from his sputum, he would doubtless be easily convinced. But an early diagnosis must be established very much earlier than by the use of the microscope. To wait for confirmation of the disease by means of the microscope is to wait until possibly the patient is beyond cure; or, if not, cured only at very great effort and expense.

Another extremely difficult matter to be met is the unwillingness of a patient, who, having been treated at a sanatorium and recovered his normal weight, feels perfectly well—yet needs weeks or possibly months of sanatorium regimé honestly and faithfully continued before recovery can be sufficiently established to warrant his return to business or his usual employment. All sanatorium workers appreciate this difficulty, and are often unable to meet it in the individual case. Here again the education of the public is needed in order that the indi-

vidual may be impressed with the necessity for these extra months of sanatorium life that seems to him unnecessary. It has often been observed that too great haste in returning to active life induces a worse condition than before, from which recovery is often extremely difficult if not impossible.

Another interesting result of the recent study of the sources of contagion in tuberculosis is now appearing in medical literature. Dr. Koch, at the London Tuberculosis Congress in July, 1901, as all medical men know, expressed the opinion that there was no communicability between the human and the bovine forms of tuberculosis. He undoubtedly made this statement rather hastily, not having been able to communicate human tuberculosis to the bovine race. A positive difference in appearance is readily noted by all observers between these two organisms. By experimentation upon most animals the bovine organism is acknowledged to be more virulent, yet there is coming to the surface now an opinion—perhaps not fully established—that either organism may be cultivated into other forms more or less virulent, by growth in other animals than those from which it was taken. And that type of organism found in a given bird or animal is simply the one to which the given bird or animal has been exposed. Furthermore, for the last four years, at least, beginning, perhaps, with Dr. Ravenel in this country, tuberculosis in the lung is positively shown to have occurred as the result of taking the organism into the digestive tract alone. Some of these observations have been made by the United States Department of Agriculture. Experiments made by Superintendent E. C. Schroeder and his assistant, W. E. Cotton, would seem to prove that ingested tuberculous organisms are the more frequent cause of tuberculosis of the lung in animals, and they believe with Cadeac, a French investigator, that we are making too much of the inhalation theory, and must substitute for it, as a far more common method of infection, the one here mentioned, through the digestive tract.

According to recent dispatches, as late as February first, the British Royal Commission established in 1901, after the famous statement of Dr. Koch, of Berlin, have recently handed in their report, and it is directly in line with the thought here brought out, that in the majority of cases the infection is through the digestive tract. Our own investigators at the Bureau of Animal Industry at Washington also bring out the astonishing fact that the feces of cattle, whether they are affected with advanced tuberculosis, or only very slightly, as shown by the tuberculin reaction, or if they are only fed the bacilli in drinking water, show the presence of the tuberculous bacilli distributed evenly through the entire length of the digestive tract. In these cases the bacilli being virulent, as shown by producing tuberculosis in inoculated guinea pig, even when inoculated with milk soiled with the feces of cows.

Most certainly would it seem from these conclusions that we have made no mistake in dealing, as we have, so effectually with the tuberculous dairy cow. The only conclusion must be that milk, butter and cheese must not be produced from any dairy cow suffering with tuberculosis.

While we can not ignore in any sense the inhalation theory, and must still believe tuberculosis to be in a sense a house disease, we are compelled by these observations to admit that tuberculosis is also a food disease.

[Written for the MEDICAL BRIEF.]

The Early Diagnosis of Gastric Cancer.

BY MACLAY LYON, M. D.,

Professor Diseases of the Stomach and Intestines, Hahnemann Medical College. Kansas City, Mo.

One of the leading authorities on stomach diseases has said that one per cent of all deaths are due to cancer of the stomach. While this statement is possibly a trifle wild, yet the fact remains that there is an alarming number of fatalities from this disease.

It is in the early and accurate diagnosis of this lesion that the only practical results may be obtained. When the tumor is apparent, cachexia present, emaciation progressing and pain unbearable, it is easy to make the diagnosis, but it is prob-

ably too late to help the patient. It is the early diagnosis which yields results; this, before the tumor is as large as a hen egg, before the patient is as yellow as a pumpkin, and before the offensive breath, rapid emaciation and terrible pain are present to startle you, and to set the patient adrift seeking this one and that one in hope of relief, and, perhaps, falling into the hands of that vulture of medical practice, the advertising quack, who guarantees to "cure cancer or money refunded"—maybe.

To make a diagnosis of gastric carcinoma early in the disease, it is necessary to obtain the family history in detail. Some will give a history of mother or grandmother having died of a disease which was said to have been cancer of the stomach. The patient's weight at the time of examination, and three months, six months, and one year previously, is important. The story of the increasing indigestion and the attacks of pain, condition of bowels; and, in fact, each and every symptom of the patient which is peculiar to the patient, should be noted carefully. With the history at hand, the other points in the diagnosis are much more easily obtained, and more trustworthy.

Gastric cancer may be extremely painful, and may be nearly painless; there may be frequent vomiting of blood-streaked mucus, and there may be little or none.

The presence of lactic acid in the vomit in a proportion of 1/1000, or greater, is a diagnostic sign of value, provided the other conditions agree. This may be found before the tumor can be felt. The condition of the gastric juice is similar to that in chronic gastritis. There will be a localized tenderness in cancer, however, and a progressive emaciation. Microscopical examination, if a careful aspiration of stomach contents is made, will reveal the spindle cell of carcinoma. Its arrangement and grouping will determine largely the progress of the invasion. If a culture be made, the Boas-Oppler bacillus will develop, and can be demonstrated.

The presence of succinic acid in the vomit, which looks somewhat like bile, and is often mistaken therefor, is another link in the chain of diagnosis. It is sometimes present in chronic gastritis, but is found in large quantities in cancer. It is supposed to be a product of mold, and is productive of the formation of much gas in the stomach.

Upon very close examination the cachectic hue may be discovered by the physician long before the patient or family realizes its presence.

By chemical and microscopical examination of the vomit, testing for the size, position and shape of the stomach, locating the point of tenderness by external and internal methods; learning the motor sufficiency and glandular condition of the stomach, and comparing it with the history and symptoms, a diagnosis can be made which will be accurate, but which the patient may refuse to believe. Indeed, the average layman will scoff at the idea of such a possibility, unless he is half dead with the disease, and it has been told him repeatedly.

But when such a diagnosis has been made, there is hope. Surgery may cure the condition; diet, hygiene and the indicated remedy will do much, and the adjuvants, as electricity and light rays, all will help.

I believe that gastric cancer is curable under these conditions.

My plea is for a more careful study of the digestive disorders, and more accuracy in diagnosis. We owe it not alone to our patients to discover the disease in time, but to ourselves. The old adage of a stitch in time, holds good in the early diagnosis of gastric cancer.

Static Electricity in Traumatic Paralysis.

BY H. P. JENSEN, M. D.,

Professor of Electro-Therapeutics in the Medical Department of the University of Nebraska. Omaha, Neb.

I have chosen this title in order to call your attention to some cases of traumatic paralysis which I have treated by static electricity. Within the past few years I have succeeded in curing about twenty cases of this form of paralysis, but I shall only describe three cases, since the treatment of these has been more or less simi-

lar, and also because the cases herein described have been referred to me by Dr. Jonas, and the diagnosis does not, therefore, depend on me alone.

Case 1.—H. M. B., aged thirty-two, residing at Rawlins, Wyo., engineer by occupation, presented himself for treatment April 14, 1900, with the following history: About eighteen months previous he sustained a severe injury of the left shoulder and arm, while trying to reverse his engine. The lever, owing to some defect, slipped and caught him by the left wrist, forcing him through the cab window, and pulling him back again. It seemed to him as though his arm were being pulled from its socket. On freeing himself from the reverse lever, he found he was unable to use his arm. He was taken to the hospital at Laramie for treatment, where he remained for six months without improvement; after which time he was sent to the hospital at Denver, Colo., remaining there one year. Here he was finally informed that the arm was lost so far as ever obtaining any use of it was concerned, and amputation advised. This advice was refused by him, and, having heard of the Indianapolis Surgical Institute, decided to visit it and make another effort toward bringing about a cure. On his way, he stopped in Omaha to consult Dr. Jonas, who advised him to try what static electricity would do, and he was sent to me.

I found complete paralysis of the left shoulder, arm and forearm. There was great wasting of the left deltoid muscle, as well as all the muscles of the arm and forearm. The muscles would not respond to the faradic or galvanic current, and reaction to powerful static sparks was barely perceptible. The treatment consisted in static sparks for ten minutes, daily, applied to the forearm, arm and shoulder, as well as up and down the spine. This was followed by a static positive breeze for another ten minutes. In ten days, after commencing treatment, the muscles responded fairly well. In three weeks he was able to move the arm and to raise it from the side of the body to an angle of forty-five degrees. In five weeks he could use the arm in feeding himself. On the sixteenth day of June, 1900, he was discharged cured. When I last heard of him he was again doing duty as a railroad engineer.

Case 2.—F. S., aged twelve and a half years. At the request of Dr. Jonas, presented herself for treatment December 22, 1902, with the following history: In June, 1902, she fell down stairs injuring the left elbow. Two physicians were called. One diagnosed a dislocation of the left elbow joint. She was chloroformed, and an effort made to reduce the dislocation by traction. The physician placed his heel in the axilla and manipulated the arm for about two hours. Another physician, called in consultation, pronounced the dislocation reduced. When the patient recovered from the anesthetic she found the arm paralyzed.

When I saw her the arm was much in the condition of Case 1, except that the static sparks gave her pain, and she refused to be treated by this modality. I then tried the galvanic and faradic currents for about two months, with no result. I was about to send her home, when I succeeded in persuading her to again permit the use of the static current. The sparks were painful, and they also failed to move the muscles to any great extent. I then determined to try the wave current; this seemed to act better, and gave hopes of success. One day, in using this modality, I forgot to have the Leyden jars in circuit, and was greatly surprised to find that the muscles could be moved with great facility, and considerable power. After this I used this modified wave current daily, and within three weeks I was gratified to be able to discharge the patient with good use of her arm.

Case 3.—L. F. H., aged seventy years, referred to me by Dr. Jonas, with the following history: The fall previous, while engaged in hauling hay, he attempted to help the team by pushing against the hind wheel. The ground was slippery, and the horses missed their footing, permitting the wagon to run suddenly backward, throwing him under the wheels, injuring his right arm and shoulder. On getting up, he found his arm very painful and useless. When I saw him the arm and fingers were much swollen; movement almost *nil*, and the pain was so great that sleep was impossible. The

treatment instituted in this case was static sparks, given for about fifteen minutes at each sitting, daily. April 29th, three weeks after beginning the treatment, the arm was very much improved; pain was entirely relieved, and some motion was obtained. At this time, hearing that his wife was about to die, he was obliged to hurry home, and treatment was ended for the time being. I did not see him again until last September, when he called to show me that improvement had continued, and to express his gratitude for my services.

My reason for calling attention to these cases is because I believe that this method of treatment is not generally recognized by the profession; or, at least, it is not given the prominence which it deserves.

A Plea for the Better Understanding of the Principles of Laboratory Diagnosis.

BY H. M. GOODMAN, M. D.,

Professor of Medical Chemistry and Clinical Professor of Diseases of the Chest in the University of Louisville, Medical Department.
Louisville, Ky.

It is certainly a most deplorable fact that many of our most prominent practitioners are either absolutely ignorant of, or totally indifferent to the methods of laboratory diagnosis. We may account for this to some extent when we consider that many who are still engaged in active practice graduated at a time when our knowledge of this important department of physical diagnosis was in its infancy, but it unfortunately applies to just as many who have had ample instruction under competent teachers. Yet, in spite of such advantages, their lack of interest to properly appreciate the most ordinary tests is simply appalling. While it is true that many new and complicated methods have been introduced, and numerous instruments of precision involving principles difficult to understand have been added to the physician's armamentarium, and it has been discovered that there are other things in the urine that produce exactly the same results with test reagents as the substance whose presence we are endeavoring to determine, or that certain harmless bacteria have many of the morphological characteristics of the pathogenic bacteria, it does not follow that we should cease to continue the search for other means of differentiating them. I doubt very much if the patient would rest the diagnosis of his case with that physician who asserts that he can find albumin by the heat and nitric acid test, or sugar with Fehling's solution, to the exclusion of all other tests for these substances, provided that the patient knew beforehand of the doctor's limited knowledge of the subject. I also very much doubt if the aforesaid patient would willingly submit his case to that practitioner for treatment if he knew that the chemical tests were performed by some medical student or recent graduate. I have, on many occasions, seen physicians when testing urine for albumin, simply boil the specimen; and others with a quasi-scientific flourish, add a few drops of nitric acid and proceed to boil the specimen, seemingly indifferent to the fact that something else aside from albumin may be precipitated from urine by heat alone, or that serum albumin, if present, may, in the presence of nitric acid, form an acid albumin which is not precipitated by boiling the specimen. Other difficult, misleading and improperly conducted tests are daily made for the purpose of ascertaining the presence or absence of sugar. We must bear in mind that there are substances other than dextrose that reduce the salts of copper, or that produce effects similar to those of sugar with other reagents. If the urine contain pentose, which may reduce the salts of copper, form osazones with phenyl hydrazine, does it not necessarily follow that we should be able to differentiate that substance from dextrose by appropriate tests, rather than to make an otherwise healthy person unhappy, and to subject him to unnecessary medical treatment for a condition of disease that does not exist?

If we are to depend upon the ability of others to do this work for us, is it not

easier to submit the specimen for examination to an expert, rather than to a second or third-year medical student, or recent graduate whose ability to differentiate the findings in the urine, both of a microscopical and chemical nature is questionable, and whose knowledge of these findings in relation to the clinical findings of the case is certainly very obscure and immature? Who among us would think of depending upon the knowledge of a student or recent graduate to diagnose a case of typhoid fever, or to tell us whether a certain enlargement in the female abdomen was due to pregnancy or to some condition of disease? Yet we unhesitatingly consign both our reputations and the lives of our patients to the crude manipulations of the student for an "expert" opinion upon the microscopic and chemical findings of the urine, and various other secretions and excretions of the body. The analogy is the same. We are willing to admit that we are unable to make a differential diagnosis of certain lesions in the pulmonary or pelvic viscera, and must, perforce, call to our aid an experienced diagnostician; so should we admit our inefficiency and submit our specimen to the examination of one whose knowledge and judgment we can depend upon.

In my opinion there is no reason why every physician and specialist engaged in the practice of medicine should not have sufficient knowledge of chemical and microscopical technique to enable him to determine the presence or absence of abnormal ingredients, the nature and character of the urinary sediments and the method employed in the staining, and recognizing the various pathogenic bacteria. The time-honored excuse that the busy practitioner has no opportunity for the study of clinical diagnosis is not true, and that man who is willing to hide himself behind this screen of ignorance not only risks his own reputation but jeopardizes the lives of hundreds of innocent persons who intrust their health into his keeping.

I will admit that it costs money; it takes time; it costs many hours of weary research, but in the end it will bring money and reputation to him who endeavors, by his own efforts, to use the methods and instruments of precision to arrive at an exact understanding of his patients' diseases.

Diagnosis should come first; therapeutics and the scalpel afterwards.

How the Family Physician May Become a Safe Counselor in Diseases of the Eye

BY JOHN E. MINNEY, M. D.,

Professor of Ophthalmology and Otology in the Kansas]Medical College; Oculist and Aurist A. T. & S. Fe Ry., and the C. R. I. & P. Ry. Topeka, Kan.

The family doctor is called upon to distinguish and treat all ailments of the human body. He sees these cases first—anything and everything, from alopecia to ingrowing toe nail. The family doctor is a man of many parts. It is impossible for him to be an expert in all diseases, but there are a few salient points in the specialties that he can master, and in this way he can become a safe counselor in special ailments. This is particularly true of diseases of the eye.

There are two diseases of the eye which are easily learned; two of the most deadly and destructive to sight, viz.: iritis and glaucoma. A physician who will learn to diagnose these two conditions is a comparatively safe man to treat eye diseases.

There are more eyes lost from the failure to diagnose these two diseases by the general practitioner in their early stages than any other form of eye disease. The damage is done usually early in the disease, and when a specialist is finally consulted, the destruction is often complete. Iritis will form adhesions within a few hours that are difficult to break up. A glaucomatous eye may be permanently destroyed within a few hours, or at least within twenty-four or forty-eight hours. The characteristic symptoms of iritis are pain, photophobia, contracted pupils, turbid aqueous, red, rosy ring around the cornea. The treatment is atropin, locally. In seventy-five per cent of the cases iritis is of syphilitic origin, and a mixed treatment, combined with the atropin is indicated.

In glaucoma we have usually pain, increased tension or hardening of the eyeball; a dilated pupil, rings of light around a lamp flame, temporary loss of sight, with recovery, and then eventually total loss of vision. The treatment is eserin; hot fomentation; if the pain is excruciating, hypodermic injections of morphine. And in both cases rest of the eye.

The prognosis of iritis is good when seen early, even of syphilitic origin. The cause of glaucoma is unknown, and its prognosis always guarded. If eserin does not relieve, a broad iridectomy should be done. In glaucoma the pupil is dilated, which is a characteristic symptom, with hardening of the globe. In iritis the characteristic symptom is a contracted pupil, with red, rosy ring. In glaucoma atropin is strictly contraindicated; it favors the increase of the disease. In iritis atropin is the remedy.

Rigidity of the Os.

BY J. T. BRYAN, M. D.,

Professor of Obstetrics, Embryology and Clinical Pedology in the Southwestern Homeopathic Medical College and Hospital.
Louisville, Ky.

Rigidity of the os is one of the most, if not the most, frequent causes of dystocia, and to which, with perhaps one exception—the injudicious use of ergot—is due the majority of cases of lacerated cervix.

There are three varieties of rigidity of the os.

1. The anatomical; that form found in miscarriages, premature deliveries and old primiparæ, dependent upon a lack of thorough softening of the cervix.

The diagnosis of this variety rests upon the condition of the cervix as revealed to the examining finger. The os is found thick, tough and heavy, non-sensitive.

The treatment resolves itself into promoting ease and comfort, as far as possible, and safety to the mother, by the use, if needs be, of anodynes; the hot sitz bath, or the hot douche of simple sterile water adds greatly in the softening process. Time and patience are necessary factors in caring properly for this condition.

The second variety of rigidity of the os, the spasmodic, is found especially in those highly nervous patients that have not been taught self-control. The examining finger finds the os, which is more or less hot and febrile, and usually thin, quick to respond to its touch; the most exciting cause is undue manipulation and too frequent examination.

This condition is treated by the hot sitz bath of from fifteen to twenty minutes' duration. Of the internal remedies cimicifuga is indicated by the history of ovarian irritation, rheumatic affections, chorea in early life, vertigo, and occipital headaches. Belladonna is indicated by the congested condition of the head, face; os extremely irritable; hot and dry, and the patient of the full plethoric type, subject to frequent congestive headaches. Pulsatilla adapted to the blonde phlegmatic individual; tearful and despondent, and who is subject to catarrhal discharges, especially if there be a history of otorrhea and conjunctival troubles in childhood. Chamomilla for the mean, spiteful, impatient individual. The bryonia patient is similar in her mentality to the chamomilla patient, but is more determined, and often vindictive. She gives you a history of constipation, and rheumatic tendency affecting the fibrous tissues.

These remedies I prescribe in the 3x potency, with the exception of chamomilla, which I administer in the 30th. I would not say that these remedies invariably cure the condition, and are all that is needed, for, at times, I am forced to resort to chloroform inhalation, or to belladonna or opium suppositories.

The third variety, the pathological, embraces the rigidity due to any pathological condition of the os, or cervix, such as hypertrophic elongation, contractions from cicatrices, small fibroids, atresia or contractions from escharotics, cancer, etc.

The diagnosis is easily made from the physical condition present and revealed to the examining finger. The treatment is largely mechanical; dilatation being assisted by the Barnes' water bag, or the fingers, either before or after incisions. Seldom, however, is it necessary to incise the os. Where you have a cancerous con-

dition to deal with incision is made through the healthy portion of the cervix, severe hemorrhage being less likely at this point than through the diseased portion. In prophylactic treatment I administer such remedies as cimicifuga, caulophyllum, pulsatilla and sepia during the last weeks of pregnancy, prescribed upon their specific indications; these will do much to prevent the development of the spasmodic variety, to favor vital dilatation, and to that extent prevent the anatomical. I question the effect of these drugs upon the pathological form.

[Written for the MEDICAL BRIEF.]

Complications and Accidents Following Tooth Extraction.

BY CLYDE DAVIS, B. S., M. D., D. D. S.,

Dean of Lincoln Dental College Associated with the University of Nebraska; Professor of Operative Dentistry in Same.
Lincoln, Neb.

Fracture of Other Teeth Through Striking Them With Forceps.—When a tooth which you are attempting to extract suddenly loosens, it is unfortunate if the forceps come in contact with other teeth, and their injury could only result through carelessness. If the necessary amount of caution is taken beforehand, it can be avoided. This accident is most likely to occur in the extraction of the third inferior molars and inferior bicuspids, as the direction of the force necessary for their extraction is in a line which would bring the forceps against these upper teeth, if the tooth is suddenly loosened.

One of the principal precautions is to see that the patient's head and the muscles of the arm you are using are fully under control. The muscles of the arm are under better control when the tooth to be extracted is near the operator's body. Another precaution is to take a piece of flexible dark-colored rubber tubing about three inches long, and of about one-half to three-quarters-inch bare. Split this with a knife half its length. Slip the rubber tubing over the forceps, allowing the unsplit portion to cover the hinge of the forceps, and part of the beaks, and allowing the split portions to extend upon the handles of the forceps separately, wrapping them securely to each handle with strong linen or silk thread. Thus wrapped, if the forceps should accidentally strike the upper teeth they will not be fractured.

Laceration of Soft Tissues.—The laceration of soft tissues of the mouth may be prevented by severing them at the neck of the tooth from the alveolar border, and placing the forceps beneath this. I do not think it necessary to in any case impinge upon or pinch the soft tissues with the forceps. If room is needed for the beaks of forceps, sever the soft tissues from the periosteum, and leave them intact to form flaps for covering the wound.

There is also danger of pinching the lips with the hinge of the forceps. The joints being made at right angles, and shutting very closely, but little force is required to entirely sever the impinged portion from the lip. This can be avoided by seeing that the lips do not touch the forceps at this point.

There is danger of still another injury to the lips by allowing them to overlap the other teeth, and by pressure with the fingers or handles of the forceps, or through the teeth suddenly leaving the socket, striking the teeth in the other jaw, with the lips between. A little care on these points will save great annoyance to patients and chagrin to the operator.

After Pains of Tooth Extraction.—When the nervous system has been wrought up to a high tension through continued pain, the mere removal of the teeth, thereby severing the nerve of its pulp near the apical foramen, does not, in all cases, immediately relieve the pain, and patients will sometimes complain of toothache after the tooth has been removed. Sometimes this will last only a few moments, in other cases for hours, and patients will complain of certain pains in the process formerly occupied by teeth, after wearing an artificial denture for years. They declare these pains identical with those suffered when they were possessed of these organs.

Such phenomena, with reference to the nerves, are also illustrated by what surgeons tell us of persons having aches and pains which seem to be in their fingers

or toes long after these members have been amputated.

Where the pain is long continued there is little to do but resort to general treatment. Most frequently troubles of this nature are of short duration, lasting but a few moments, or hours, at most. Great relief may be given by injecting into each root-socket a few drops of a preparation known to the dental profession as Heaven's cordial. The formula is as follows:

℞ Alcohol ..... 1 ounce.
Chloroform ..... 2 ounces.
Sulphuric Ether ..... ¾ ounce.
Gum Camphor ..... ½ ounce.
Laudanum ..... ⅛ ounce.
Oil of Cloves ..... ½ drachm.
M.

This will also be found to be a good toothache remedy.

Should Teeth be Extracted While Aching?—Some of our authorities advise that we should not extract teeth while they are still aching, having in mind some of the very troublesome cases of neuralgia that sometimes follow the extraction of an aching tooth.

It is generally believed by the dental profession that this is improper advice and poor practice, since there seems to be no better time than the present for the removal of a tooth which can be made of no further service. Advice to allow an aching tooth to remain in the mouth while you attempt to stop the pain, will not be charitably received, and in most instances the patient will go directly from your office to another, and have the tooth removed. The cases are so few in which the pain is prolonged beyond a reasonable length of time, that we do not hesitate to extract a worthless tooth at any time, unless the patient's health would forbid. The fact that a tooth is badly ulcerated and seated in a pus pocket, is no more reason for allowing it to remain than you would refuse to lance an abscess on the plea that you desired nature to take its course. In a bad case of the formation of acute alveolar abscess the tooth itself is almost invariably the excitant cause. The sooner the cause of the pathological disturbance is removed the less far-reaching are the ill-results.

Taking Cold in the Teeth—Every practitioner is asked, after the extraction of a tooth, if there is danger of taking cold in the wound. It is also the belief of the laity that when they have the formation of an acute alveolar abscess, or the revival of a chronic one, they have taken cold. Patients, upon your taking exception to this view, will say that their physician said such was the case. This is not a wise plan, for it advises patients directly opposite to the truth, for no physician believes that an alveolar abscess is the result of taking cold.

Resorption—As in the case of other hard tissues of the body, absorption of the alveolar process is of two kinds: physiological and pathological. Physiological absorption of the hard tissues is that absorption resultant upon the performance of an organic function in an organism in a state of health, the products of which are excreted. As an illustration, I would cite the removal of the alveolar process, retaining the temporary teeth, which is afterwards replaced by the permanent process; also the removal of the permanent process after the permanent teeth have been removed, leaving the jaw much smaller, as it is found in extreme old age.

Pathological absorption of the hard tissues is that resultant upon a pathological action in an organism in a state of disease, some of the products of which are exfoliated. As an illustration, I would cite the removal of the hard tissues in the body resultant upon a destructive pathological action, such as the formation of abscess within a bony cavity.

The absorption of the process around the roots of the deciduous teeth, as well as the absorption of the roots themselves, is physiological absorption, and just as long as this process continues, with the adjacent tissues in a state of health, it is normally accomplished. If, for any reason, physiological absorption is interrupted by a pathological condition, physiological absorption ceases. This explains why the roots of temporary teeth are not always absorbed. For, if the pulp in a temporary tooth dies, there is always a little inflammation, or, perhaps, an abscess at the base of the root, and nature ceases her work, and any subsequent absorption, either of the alveolar process or the roots of these temporary teeth, would be pathological. The oncoming permanent teeth may check physiological ab-

sorption in the deciduous teeth by pressing upon or coming in contact with the remaining roots of the temporary teeth, and again nature ceases her work. For this reason I do not believe in the theory advanced by some authorities—that a temporary tooth should not be removed unless it is loose or decayed. Allow this in nowise to interfere with extraction. If the patient has arrived at the proper age, and this is the next tooth in order to be replaced, extract it, paying no attention to the lack of absorption, as some pathological trouble may have checked it.

The absorption of the alveolar process after the removal of a permanent tooth, or the entire denture, is physiological, and nature's way of grading up the mouth to an even and level surface. I do not think the Creator, when constructing the architecture of the oral cavity, had in his mind the wearing of an artificial denture, and he has provided for the possibility of leaving the mouth in such a condition that food can be masticated. This could only be accomplished by the removal of the sharp portions of the alveolar process left standing after the loss of the teeth, and then thickening the membrane over the alveolar ridge.

Therefore, we have the drawing away of this, which can be called the superstructure of the maxillæ, as a foundation for the support of these useful organs.

Richards Block.

Homeopathic Indications for a Few of the More Important Drugs in Eye and Ear Diseases.

BY ELBERT B. SWERDFEGER, M, D.,

Professor and Demonstrator of Anatomy; Chief of Eye, Ear, Nose and Throat Clinic. Denver, Colo.

The men who are the most successful in their practice in this specialty are those who give the greatest attention to detail, and prescribe for their patient as a complex being, rather than as an individual consisting only of eyes and ears.

In order to illustrate what I wish to convey, I will describe a case at the clinic some years ago: Mrs. N., married, aged thirty-eight, with the following history: For the past four or five years had several ulcers on one or the other eye; each ulcer making its appearance following a death in the family, or grief or anxiety. Upon examination I found a deep ulcer on the outer portion of the cornea of the right eye, with photophobia, marked lachrymation, excruciating pain. The present attack followed the attendance on a very sick child. Patient always worried greatly. She was given the regular routine local treatment for such conditions. Internally, she was given ignatia. This drug was not given because it has such marked effects upon the eye, but because it is one of the greatest known remedies for the relief of morbid conditions, whether found in the eye or elsewhere. The woman was cured in a few weeks, and for over three years she has had no return of the trouble.

In taking up drugs under a special heading, one can give but a few of the important indications that have been found clinically to be of the greatest use.

Agaricus.—This drug produces jerking, twitching and trembling of various muscles or sets of muscles, also burning and itching. Hence we find it useful in diplopia, asthenopia from prolonged strain, spasms of accommodation, twitching of eyelids and eyeballs. There is no drug in our *materia medica* which equals it in the treatment of after-results of frost-bitten ears or toes, where they itch and burn.

Allium Cepa.—We have all worked over a strong onion, and had our eyes filled with non-excoriating tears, and our nose secreting acrid discharges. When we find such a condition existing in a patient, allium cepa will relieve it. We frequently find the above conditions in hay fever.

Apis Mel.—Those of us who have been stung by a bee know there is a great deal of stinging, as well as burning and edema with this drug. In the eye it is useful when the lids are edematous, are everted, inflamed, sting and burn; conjunctiva, bright red and puffy. Hot lachrymation, sudden, piercing pains. Keratitis, with intense chemosis of ocular conjunctiva.

Arg. Nit.—A deep-acting drug, with marked effects on the whole nervous system, and on the mucous membranes. Patient has an old, pale, bluish appearance.

There is blurred vision, photophobia; worse in a close, warm room. Inner canthi swollen and red. Purulent ophthalmia, having an abundant, thick discharge, eyes shifting. One of the very best drugs in ophthalmia neonatorum.

Aurum Met.—Here is a drug that attacks the blood, glands and bones, and produces a condition simulating mercurial, or syphilitic poisoning. This drug produces a morbid condition of the mind. Patient is hopeless, despondent; talks and thinks of committing suicide, and seeks every opportunity to accomplish self-destruction. All of the symptoms of this drug are worse in cold weather, and at night. As this drug attacks the bones, it is one of the best drugs in caries of the ossicles and the mastoid. Frequently useful in obstinate fetid otorrheas, whether following grippe, scarlatina, or from any other cause. In the eye we find extreme photophobia. Either diplopia, or only the lower half of objects visible. Vascular cornea. Pains seem to come from without and pass inward.

Belladonna.—A drug that produces active congestion. On the nerves, it produces a perverted condition, with twitching, convulsions and pains. In any typical belladonna condition, there is always a hot, red skin, flushed face, glaring eyes, dilated pupils, throbbing carotids, mental excitement. Pains come and go suddenly. In the eyes there are throbbing, dilated pupils; eyes feel swollen and protruding, diplopia. In the ears we find bulging membrana tympani, otitis media, throbbing, beating pains; all of which are worse with the head down, or the patient lying down. Hearing very acute. The child cries out in sleep.

Calcareas.—These are some of the chief tissue remedies which are especially indicated in tardy dentition, with the troubles incident to that period. Bone disease, nonunion of fractured bones, anemias, chronic wasting diseases. These symptoms are aggravated from changes in the weather, and generally have a numbness and a crawling or creeping sensation. Patients perspire easily; enlargement of glands; in other words, a nice picture of a scrofulous condition. In eye diseases, or any condition which may present itself having the above set of symptoms.

Capsicum.—We find this drug most often indicated in persons of lax fiber, or weak from diminished vitality. They are generally persons who are fat, indolent and opposed to physical exertion. Mind easily disturbed. In the ears we are apt to get a burning, stinging, swelling pain. Mastoiditis, tenderness over the petrous bone. Extremely sensitive to touch. Added to this there are the above general symptoms, and usually a general chilliness.

Conium.—A drug rendered classical by Plato's graphic description of its employment in the death of Socrates. If taken to excess, it produces an ascending paralysis, which ends in death by failure of respiration; sudden loss of strength, of walking; these conditions are frequently found in the aged, or those whose vitality has been depleted by some disease. In the eyes we have photophobia, excessive lachrymation; worse by artificial light; paralysis of one or more of the ocular muscles; inflammation of the conjunctiva, or cornea. A peculiar thing is that a slight laceration or abrasion will cause the most intense photophobia and lachrymation.

Graphites.—This drug is an antipsoria. It is especially active in patients who are stout, fair complexioned, with a tendency to constipation. Fat, chilly and easily exhausted; indication for graphites.

Eyes.—Ophthalmia, with intolerance of artificial light. Eyelids red and swollen. Blepharitis marginalis. Eczema of lids. Fissure of canthi, particularly the outer. Zincum—the inner.

In the ears there is dryness of inner ear, cracking when chewing; hissing. hardness of hearing. Thin, white, scaly exfoliation covering membrana tympani. Fissures and eruptions behind the ears, which ooze out a thin, sticky, glutinous exudate. Patient worse at night. If a woman, better during and immediately after menstruation.

Hepar Sulph.—This drug suits those of a scrofulous or lymphatic constitution. There is always great sensitiveness to all impressions. This drug is always thought of, either where pus has formed or where it looks as though it would occur. If given early enough, will very often abort the pus formation. Under the general

symptoms there is generally chilliness, hypersensitiveness, pains are splinter-like; craving for sour and strong things. A feeling as if a cool wind were blowing on the part affected. Hepar is a good drug to be used in corneal ulcers, iritis, purulent conjunctivitis, with marked chemosis. Profuse discharges, great sensitiveness to touch and air. Objects appear red, and too large. This is as near a specific for hypopyon as any drug is a specific for any morbid condition—a fact I have seen verified time and again. The ears have a thick scurf on and behind them. In chronic suppurative otitis media the pus is thick and very offensive. All conditions are *worse* from dry cold, from mercury, touch or lying on painful side. Better in damp weather, warmth and eating.

Kali Mur.—This being a potash, we find the characteristic weakness, anemia, soft pulse, coldness, general depression, sensitiveness to all climatic changes and intolerance to cold weather, the same as all of the potashes.

This drug is particularly useful in catarrhal affections which have fibrinous exudations and glandular swellings. White or gray coating on base of tongue. Expectorations thick, white and tenacious, are strong indications.

In the ear, this is one of the chief drugs in treating catarrhal conditions. All lymphatic glands around the ear swollen. Membrane tympani has a whitish appearance. Tinnitus aurium with snapping and noises in the ear. Kali mur. and merc. dulc. are two of the most prominent drugs in treating chronic catarrhal conditions, and their local indications are quite similar, consequently one needs to be guided very largely on general instead of local appearances.

Ledums.—When this drug is indicated we always find a lack of animal heat, and at the same time find that artificial heat is nearly, if not quite, unbearable. In contused wounds, with marked extravasation of blood, this will be found particularly useful. Injuries to the lids, conjunctiva, aqueous or vitreous, where there is this marked extravasation, will be very much benefited by being given ledum. This I have seen demonstrated numbers of times.

Lycopodium.—Almost invariably when this drug is indicated there will be found to be some involvement of urinary or digestive apparatus. Symptoms usually begin on right side, and extend toward the left, and are worse from four to eight P. M. Particularly useful in persons intellectually keen and musculary weak.

In the affections of the eyes we find it ranks first in number of cases cured of hemeralopia. Likewise, it is the drug of first choice in hemiopia, in which only the left half of the object is seen.

Merc. Dulc.—(Calomel).—This is one of the most used, also the most abused, drugs that we have in our *materia medica*, because every organ and every tissue in the body is affected, to a greater or lesser degree. Whenever calomel is indicated the symptoms are worse at night, from warmth, from damp, cold or rainy weather, and when perspiring.

In catarrhal conditions of the eye and ear, this is a handmaid of kali mur., and while the local conditions of the two drugs are quite similar, there need to be no mistakes made in the prescribing of either, if the general symptoms are taken into account.

Mezerium.—An important drug for neuralgia, especially about face and head. An extremely indicative symptom is: "The ears feel as if too open; as if the tympanum were exposed to the cold air, and it blew into the ear." This symptom has been repeatedly confirmed by every careful prescriber.

Natrum Mur.—Chilliness, great emaciation, weakness and anemia are all prominent symptoms. All mucous secretions richly charged with salt. The eyes feel bruised. Headaches of students. Muscular weakness being prominent, we find it useful in exophoria, when asthenopic symptoms have not been relieved by the wearing of properly-fitted glasses. This, I have verified many times. Letters run together; see sparks, profuse acrid lachrymation. If accommodative asthenopia, ruta is the drug most likely indicated.

Paris Quadrifolia.—A drug of not very wide range of action; the head symptoms being most marked. Eyes have "pain in the eyes as if pulled into the head; sensation as if thread drew from the eye into

the middle of occiput." This is rather an uncommon symptom, yet, when met, gives the key to a remedy which gives definite results beyond the relief of the symptoms alone. While yet in college I saw my preceptor, Dr. David A. Strickler, verify this at different times.

Psorinum.—Debility, independent of any organic disease. Lack of reaction when well-chosen remedies fail to act. Psorinum patients and all their secretions have a filthy odor. Skin looks dirty, and has intolerable itching.

Eyes.—Agglutination of lids. Blepharitis. Chronic ophthalmia that constantly recurs. Secretions, acrid and foul.

Ears.—Raw, red; oozing scabs around the ears. Offensive discharge from eczema around ears. Intolerably itching. In chronic suppurative otitis media, where the pus is so offensive that it is sickening to the aurist, I well remember my first verification of this last statement. It was in a boy about six years old that had a discharging ear for nearly a year, which so far had resisted all apparently well-directed and indicated treatment. This boy began to improve in a very few days after beginning to take two tablets, t. i. d. of psorinum, 30x. Since that time I have experienced a number of similar cases, with like pleasing results.

Pulsatilla.—A drug could be no better named than this. Any one that has ever seen the "wind-flower" swaying in the breeze, need not be very imaginative to think of a patient as being changeable, contradictory, sad, laughing, crying; when talking, begins weeping. Patient is thirstless, peevish, chilly; better outdoors. Worse from rich, fat food, though always craving sweets and pastries.

Eyes.—Discharge thick and yellow. Lids inflamed, nightly agglutination. Styes, especially of upper lids. Sub-acute conjunctivitis; particularly if patient is suffering from some gastric disturbance.

Rhus Tox.—Patient always shifting position. Worse in cold, wet, rainy weather, at night, during rest, when lying on back, or right side. Better, warmth, dry weather; motion, or when changing position.

Eyes.—Orbital cellulitis, pustular inflammations, phlyctenulas conjunctivitis. Iritis, after exposure to cold and dampness, especially when there is any rheumatic tendencies.

Ruta Graveoleus.—This drug acts upon the fibrous tissues of the body, periosteum, cartilages and tendons.

Eyes.—Here we find asthenopia from weakness of the ciliary muscle, accommodative asthenopia, which is usually shown by sensation of heat and fire in the eyes and an aching while reading. "Aching in and over the eyes." When such cases do not receive the relief expected from glasses, ruta will relieve a large percentage of them. Very recently I had a number of cases, all coming at nearly the same time, on whom I proved the above statement. In the eyes ruta corresponds closely to conium, which has more photophobia; to argentum nit., which has more of a catarrhal conjunctivitis. It applies to accommodative asthenopia, thus differing from natrum mur., which applies to muscular asthenopia, especially a weakness of the internal muscle.

Zincum.—This drug acts profoundly upon the cerebro-spinal system, producing a condition of erythrism in the brain, medulla oblongata and the spinal cord.

Eyes.—Inflammation and redness of conjunctiva; worse in inner canthi. Cases that show a tendency for the conjunctiva to become involved near the inner canthi are almost surely relieved by zincum. This drug has a great reputation for its beneficial effects in cases of pterygium, a fact that I have never verified.

Masonic Temple.

New Medical College Opened.

The Hippocratean College of Medicine, one of the few medical night schools in the United States, was formally established recently, with appropriate ceremonies, in the College building, 3412 Morgan street, St. Louis. The officers of the college are: Doctors Joseph E. Chambers, President; George Feigenbaum, Vice-President; Solomon S. Kohn, Treasurer; Emory Lanphear, Dean; A. H. Ohmann-Dumesnil, Vice-Dean; Albert W. Koch, Secretary.

[Written for the MEDICAL BRIEF.]

A Modification of the Tait Operation.

BY N. O. HARRELSON, M. D.,
Gynecologist to St. Joseph's Hospital; Surgeon-in-Chief, Swedish Hospital.
Kansas City, Mo.

There are probably no two surgeons in practice who follow out exactly the same technique and modifications in this rather delicate branch of plastic surgery, yet we get our ideas from the same fundamental principles, and all obtain results more or less perfect.

During the time I have been engaged in this special field of surgery, my methods have been revolutionized numerous times.

Briefly, the procedure that I have found most simple and practical in the majority of cases, consists of a modified Tait, so far as the flap-splitting is concerned. When the mucous membrane flap has been dissected up and the upper margin is slightly elevated, it presents the appearance of an ellipse. It is well to select the limits of the flap by the degree of closure you wish to make. I usually go above the carunculæ myrtiformis, because they have already been displaced from their original positions by the force causing the tear. In this method the anatomy of the Bartholin glands is practically ignored, and I have never seen any complications resulting from traumatism.

After the flap is dissected up, grasp same in the center line of the body with long tissue forceps, and push it backward and downward into the vaginal canal, thereby correcting the rectocele. The lower flap is grasped in the same manner, and retracted downward and backward. The wound that once had the appearance of an ellipse, now assumes the shape of two equal triangles, with a common base in the median line of the body. On either side of this denuded area, you will observe in plain view the fragmentary remains of the principal muscles that go to form the perineal body, among them being the levator ani, and anal sphincter, provided the tear extends to that point. The others are of small importance.

By this method of dissection, these muscles and their associates are thoroughly exposed, which enables you to place a through-and-through suture. It is immaterial at what point you take the initial suture.

I grasp on either side, with a small tenaculum forceps, the retracted remains of muscle and fascia, including the anal sphincter, if it is involved in the tear, and use a continuous catgut suture, which is buried, until the torn remains of muscle and fascia are thoroughly brought in apposition in the median line. This obliterates the ever-present rectocele. After that, or before, as the operator chooses, I run sweep sutures of silk-worm gut through the skin and muscle to, but not through, the vaginal mucous membrane, which is shoved into the vagina by a forceps held in the hand of an assistant.

The only reason for using the silk-worm gut suture is simply to support the buried catgut suture, upon which the success of the operation absolutely depends. All operations upon the perineum, during the child-bearing period, which destroy tissue should be discouraged and never employed before the menopause. The result of any successful operation should be the restoration of function, doing away with cystocele, thereby aiding in the relief of constipation, curing vaginal subinvolution by restoration of circulation and relief of tension.

I have employed the following operation over two hundred times in my own practice, and in that of others, and believe it to be the most practical method with which I am familiar.

After-Treatment.—I use once a day a vaginal irrigation of an antiseptic solution, permitting the patient, after the first twenty-four hours, to pass urine at will, having the nurse to douche the wound externally after each urination, to avoid the dangers of infection. The nozzle used should not be too large; a No. 10 female glass catheter, attached to a fountain syringe, is the most practical. I have never observed any ill-effects from the patient passing urine over the wound after twenty-four hours. I never remove the sutures before the twelfth or sixteenth day, because, if they are removed too soon, too much tension is thrown on the buried sutures, causing the torn muscles to separate, and leaving a concealed tear covered by the skin, and your patient is then in no better condition than before you operated.

Rialto Building.

Gastrotomy.

The death of the celebrated surgeon, Dr. Bernays, suggests to us that a reproduction of a justly celebrated case—in fact, the introduction of his career as a fearless and successful surgeon—would not be amiss, as many of our readers of today were not then in practice. This article was written for THE MEDICAL BRIEF, and published January, 1887:

Gastrotomy for the Removal of a Swallowed Knife—Recovery of the Patient—With Illustrations.

BY AUGUSTUS C. BERNAYS,

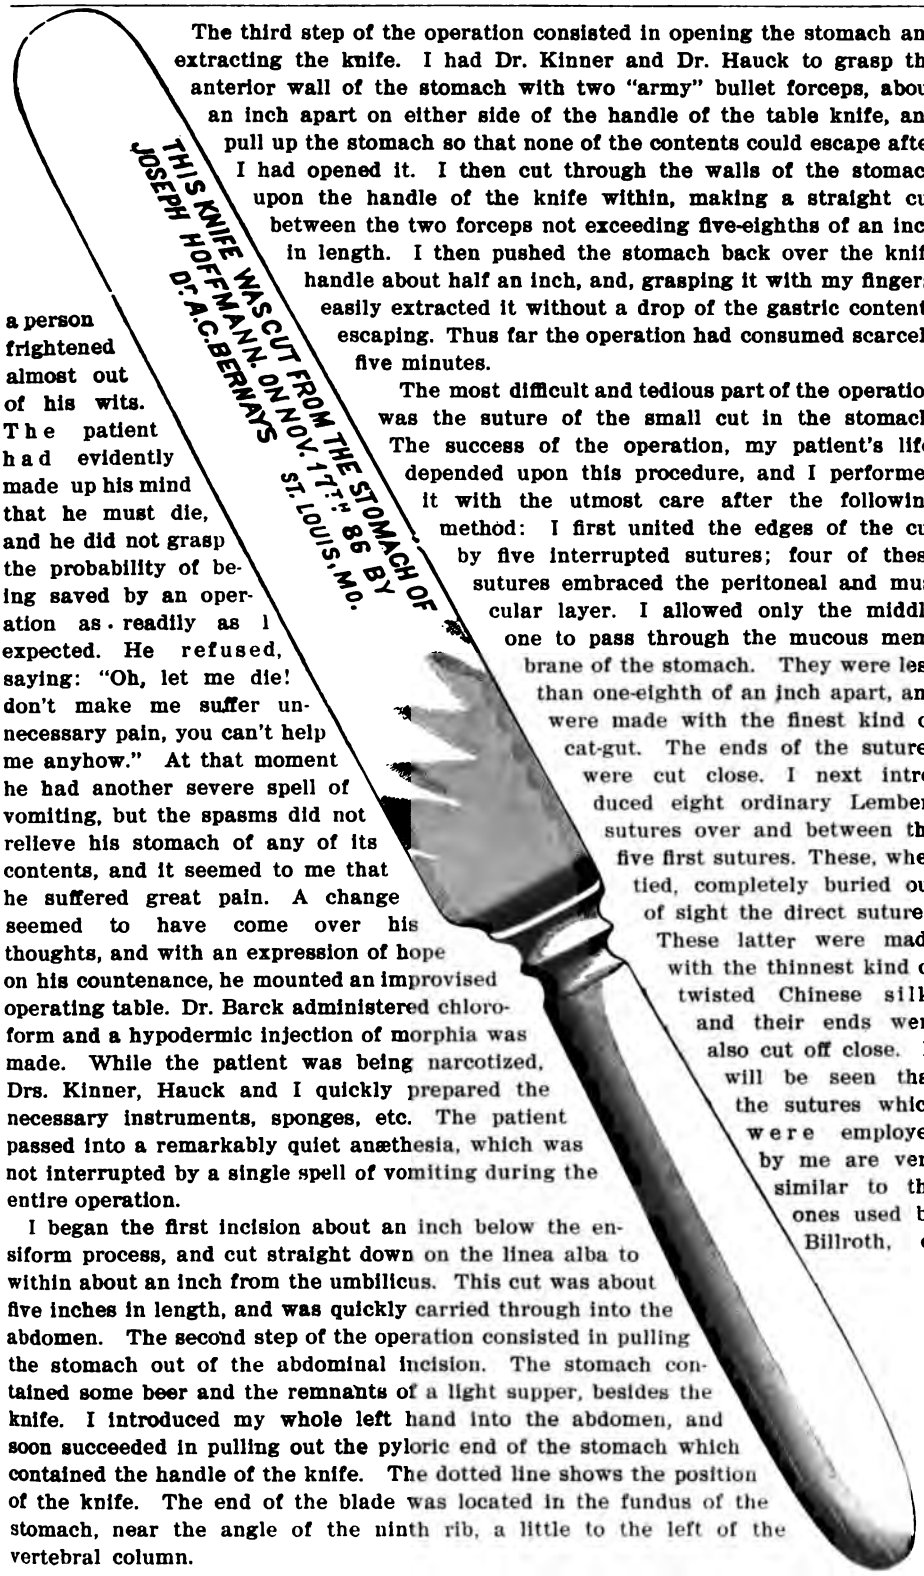
A. M., M. D., Heidelberg; M. R. C. S., England F. R. M. S., London; Member German Society Surgeons, Berlin; Professor of Anatomy St. Louis College Physicians and Surgeons.

In compliance with your request, I submit the following report of a most remarkable case for the benefit of your many thousands of subscribers:

Joseph Hoffmann, a German tailor, aged thirty-eight, was amusing his wife and children with various tricks and funny performances, at his home, No. 1207 South Broadway, on the evening of November 17, 1886. They were sitting around a table and, being somewhat exhilarated, Hoffmann intended to close his entertainment by his *chef d'œuvre*, of sword-swallowing, in which performance he is an expert. He had frequently pushed pokers, canes and handles of ladles down his gullet before, but on this evening he chose an ordinary caseknife (see Fig. 2, which is a fac-smile of the one used). He intended to make the knife disappear in his throat and then pull it out with his fingers, after the spectators had sufficiently admired his skill and daring. The first act of this program succeeded admirably, the artist pushed the knife down into his œsophagus, handle foremost, his chin being raised and head thrown back, so that the canal into which the knife was pushed formed a straight line. Suddenly, while in this position, the knife escaped the control of the performer. Amid the agonizing screams of the family and of the victim, the knife was carried down into the stomach by the contractions of the pharyngeal and œsophageal muscles. It was swallowed exactly in the same way as any other substance which is introduced into the fauces. The screams in Hoffmann's dwelling attracted the neighbors and the policeman on the beat. The latter telegraphed for an ambulance, intending to remove Hoffmann to the City Hospital, whilst others summoned medical aid. The first medical man to arrive was the family physician, Dr. Hugo Kinner, one of the busiest practitioners of the South Side. After he had assured himself of the con-

dition of his patient he quieted him, and stepping to the nearest telephone, sent for me. Dr. Kinner and I were soon in earnest consultation by means of the electric current, and it was settled that I should drive down to Hoffmann's residence, see him at once and come prepared to operate. The well known oculist, Dr. Chas. Barck, and Dr. Eugene Hauck, accompanied me to the scene of the accident.

When we arrived at the house, Hoffmann was having a violent spell of vomiting, and presented the appearance of



The third step of the operation consisted in opening the stomach and extracting the knife. I had Dr. Kinner and Dr. Hauck to grasp the anterior wall of the stomach with two "army" bullet forceps, about an inch apart on either side of the handle of the table knife, and pull up the stomach so that none of the contents could escape after I had opened it. I then cut through the walls of the stomach upon the handle of the knife within, making a straight cut between the two forceps not exceeding five-eighths of an inch in length. I then pushed the stomach back over the knife handle about half an inch, and, grasping it with my fingers, easily extracted it without a drop of the gastric contents escaping. Thus far the operation had consumed scarcely five minutes.

The most difficult and tedious part of the operation was the suture of the small cut in the stomach. The success of the operation, my patient's life, depended upon this procedure, and I performed it with the utmost care after the following method: I first united the edges of the cut by five interrupted sutures; four of these sutures embraced the peritoneal and muscular layer. I allowed only the middle one to pass through the mucous membrane of the stomach. They were less than one-eighth of an inch apart, and were made with the finest kind of cat-gut. The ends of the sutures were cut close. I next introduced eight ordinary Lembert sutures over and between the five first sutures. These, when tied, completely buried out of sight the direct sutures. These latter were made with the thinnest kind of twisted Chinese silk, and their ends were also cut off close. It will be seen that the sutures which were employed by me are very similar to the ones used by Billroth, of

a person frightened almost out of his wits. The patient had evidently made up his mind that he must die, and he did not grasp the probability of being saved by an operation as readily as I expected. He refused, saying: "Oh, let me die! don't make me suffer unnecessary pain, you can't help me anyhow." At that moment he had another severe spell of vomiting, but the spasms did not relieve his stomach of any of its contents, and it seemed to me that he suffered great pain. A change seemed to have come over his thoughts, and with an expression of hope on his countenance, he mounted an improvised operating table. Dr. Barck administered chloroform and a hypodermic injection of morphia was made. While the patient was being narcotized, Drs. Kinner, Hauck and I quickly prepared the necessary instruments, sponges, etc. The patient passed into a remarkably quiet anæthesia, which was not interrupted by a single spell of vomiting during the entire operation.

I began the first incision about an inch below the ensiform process, and cut straight down on the linea alba to within about an inch from the umbilicus. This cut was about five inches in length, and was quickly carried through into the abdomen. The second step of the operation consisted in pulling the stomach out of the abdominal incision. The stomach contained some beer and the remnants of a light supper, besides the knife. I introduced my whole left hand into the abdomen, and soon succeeded in pulling out the pyloric end of the stomach which contained the handle of the knife. The dotted line shows the position of the knife. The end of the blade was located in the fundus of the stomach, near the angle of the ninth rib, a little to the left of the vertebral column.

Table of Gastrotomies for the Removal of Foreign Bodies.

Case No.	Name of Operator.	Literature and Bibliography.	Patient—Age and Station.	Nature of the Foreign Body.	Length of time the object was retained in the Stomach.	Physical Condition of Patient before the Operation.	THE OPERATION.	AFTER-TREATMENT AND REMARKS.	FINAL RESULTS.
1	DANIEL SCHWABE, in Kœnigsberg, Prussia, 1635.	Baldinger's New Magazine for Physicians, Vol. XIII. 1791. Page 567 *Berlin Clinical Weekly*. No. 7, 1883. Hart Knochs Old and New Prussia. 1684.	A. Gruenheyde, farmer, 22 yrs of age.	Table knife, 18 ctm long, 15 ctm. broad (6¼ in. in length).	41 days.	No serious inconvenience.	Incision one and a half inches below and parallel to the ribs on the left side. Stomach pulled up by means of a curved needle Stomach cut through on the point of the swallowed knife. The incision "snapped shut" after the knife had been extracted. Abdominal incision closed by five sutures. Operation without anæsthetics	Removed external sutures on second and third day. Bloody urine, and stools during first days. Wound washed with wine—strict diet during two weeks. Wound entirely healed during this time.	The patient lived many years, enjoying perfect health.
2	TILANUS, of Leyden, 1848.	Ort, Diss. contin. casum gastrotomiae cet. Lugduni, Batavor, 1853 Adelmann, *Prague Quarterly Review of Practical Medicine*, Vol. 131, 1876, page 80.	Insane girl in the town of Zuepthen, 32 yrs old.	Silver fork, 21 ctm. long, and some pieces of crockery of triangular shape, 2 ctm. in their greatest diameter.	3 days	Very weak patient. Great difficulty of swallowing. Diagnosis is proven by sounds and by examination of region of the stomach.	Patient is anæsthetized with ether. Incision only about 3 inches in length in linea alba. Stomach is drawn forth with two forceps, an opening, one inch in length into the anterior wall of the stomach, causing considerable hemorrhage. Finding of the fork and crockery consumes time and is found very troublesome. The stomach is closed by 5 stitches, the ends of which were conducted and allowed to hang out of the lower angle of the abdominal incision. The latter was closed by a simple suture.	Vomiting of greenish fluid, pain and tympanites during first and second days. Feeble and high pulse on the second day, death on the third.	*Post-Mortem* shows plastic material which has caused a conglomeration and adhesion between the stomach, liver and abdominal parietes. The incision in the stomach entirely closed. The stomach much distended. The upper third of the œsophagus is much lacerated and perforated opposite the larynx A pus-sinus extends along the lobe of the thyroid body.
3	BELL, of Wapello, Iowa, 1855.	*The American Journal of the Medical Sciences*, 1855, July No., p. 272.	Male, aged 27.	A bar of lead 9 inches long, 1-5 inch in diameter.	9 days	No serious inconvenience at first. Vomiting on the eighth day and great prostration. The foreign body can not be detected with certainty.	An incision beginning near the umbilicus extends directly outward towards the point of the second false rib, about four inches long. The bar is extracted with a forceps through an incision which is made upon the foreign body. The contraction of the stomach suffices to close the opening. Prolapse of some intestines during the operation. Abdomen closed by the interrupted suture.	Some symptoms of gastritis. The after treatment consisted of morphine injections, two venesections and enemata. External wound healed in 5 days. Patient entirely recovered in 2 weeks.	Complete recovery.
4	LEON LABBÉ, in Paris, 1876.	*Gazette Hebdom* Second Series. XIII(XXIII) 18, 1876, p. 278.	Lausseur, male clerk, aged 18.	Fork, five-pronged; German silver.	2 years and 10 days.	No serious inconvenience for 6 months. Later on bad attacks of syncope and severe symptoms of gastralgia.	Futile attempts were made by external applications to cause adhesions between stomach and abdominal parietes Laparotomy parallel to the ribs less than two inches in length. Stomach pulled out by means of forceps. Attached to the abdominal incision by sutures before opening it. The fork was then extracted with a polypus forceps	A strong collodium cuirass was applied over the abdomen. Allowed solid food after fifth day. Wound healed nicely, excepting over the gastric fistula.	Patient dismissed on the 15th day, but a small fistula leading into the stomach was still open.

5	KOCHER, in Bern, 1883.	*Correspondenz-blatt fur Schweizer Ærzte.* 1883. Nos. 23 and 24.	Male, 37 years old.	Piece of a broken instrument called coin catcher.	1 day.	No serious inconvenience.	Oblique incision 2 ctm. from edge of ribs. Stomach secured by two loops of thread. Incision into stomach over an inch long. Coin extractor easily removed; incision closed by 10 Lembert sutures.	Careful diet, no fever, wound heals kindly.	Complete recovery.
6	GUSSENBAUER of Prague, 1883.	*Vienna Medical Weekly*, 1883, No. 51 and 52.	Professional sword swallower, 19 yrs old.	Broken sword blade 10¾ in. in length. Broken end sharp.	2 days.	Great pain, emettics, and hanging by the feet are tried. Fever, vomiting, singultus.	Operation is very difficult; the sword blade is extracted with great difficulty after the stomach was opened.	Death in two days, of septic peritonitis.	Autopsy revealed the fact that the point of the sword had perforated the stomach, and the broken end had perforated the œsophagus.
7	SCHOFNBORN, in Kœnigsberg 1883.	*V. Langenbeck's Archiv. of Surgery*, Vol. 29, page 609.	Girl, 15 years old.	Hair tumor, kidney-shaped and hard.	About 4 years.	Vomiting, a freely movable tumor in the left hypochondriac region.	Laparotomy in the linea alba. Tumor found loose in the stomach. The incision into the stomach was made parallel to the major curvature Sixty-five Madelung's intestinal sutures were employed to close the stomach.	First intention of all sutures. Dismissed from hospital after 3 weeks.	Complete recovery.
8	THORNTON, London, 1884.	*Lancet*, 1884. No. 3	Girl, 17 yrs of age.	Hair tumor, weight 2½ lbs.	Several years.	Diagnosis: Abdominal tumor. Great prostration.	Incision into the stomach was closed by several rows of sutures The tumor filled up the entire cavity of the stomach.	A sponge was left in the abdomen, but removed on the second day. Patient had parotitis of both glands.	Final complete recovery.
9	BILLROTH, Vienna, 1885.	V. Hacker, Operations on the stomach in Prof Billroth's Clinic, from 1880 to 1885. Vienna: Published by Teplitz & Deutsche.	Girl, 19 yrs of age.	Artificial denture, 6 teeth.	2 days	But little inconvenience	Incision along the ribs 4¼ inches in length, beginning near ensiform process. The foreign body is very difficult to find, but is finally extracted through a small opening, the stomach being held by two loops of thread. Some ordinary interrupted sutures and a few Lembert sutures in three rows.	The healing process goes on without any feverish reaction. Patient leaves the hospital after five weeks.	Complete recovery.
10	CREDE, Steff Surgeon in Dresden, 1885.	*V. Langenbeck's Archiv. of Surgery*, Vol. 33, page 574, 1886.	F. Mücke, a barber, 24 yrs of age.	Hard rubber denture, eight teeth & clamps	15 days.	Vomiting, insomnia, great nervousness.	Oblique incision 5 inches long parallel to the ribs, beginning near the ensiform process Stomach was drawn out. Foreign body was found near the pylorus Incision into stomach 2 inches long. Three tiers of sutures were used to close the stomach.	No vomiting, no feverish reaction, patient dismissed on the 21st day.	Complete recovery.
11	A.C. BERNAYS, St. Louis, Mo., 1886.	*Medical Brief*, St. Louis, Mo., Jan. 1887.	Jos. Hoffmann, tailor, aged 38.	Silver-plated table knife, 9¼ inches long, (24½ ctms.)	1 hour.	Frequent painful contractions of stomach, but no vomiting.	Incision in linea alba 5 inches long between umbilicus and ensiform process. Stomach drawn out and held by 2 Hegar's kugelzangen. Incision on knife handle about ¼ inch in length; 5 direct interrupted sutures, buried by a row of eight Lembert sutures. Stomach replaced. Abdominal incision closed by 18 sutures.	No vomiting, no fever. First intention; patient left his bed ten days after operation.	Complete recovery.

Vienna, in his operations on the stomach.

I now replaced the stomach in the abdomen. There was little or no bleeding, and the toilet of the abdominal cavity was very simple. The operation was finished by sewing up the external wound in the usual way. I applied about eighteen silk sutures and dressed the wound in the same manner that I am accustomed to, after ovariotomy. The dressings were held in place by an elastic web bandage. The patient was carried to his bed. He rallied quickly after having been under the influence of chloroform about an hour. The knife had been in his stomach less than an hour, before the operation.

The after-treatment was conducted by Dr. Kinner in a most judicious but strict manner, and was followed by a most brilliant result. The patient never vomited at all after the operation; his temperature reached 100° F. only on one occasion, for a short time, and his pulse never exceeded 86. He was given a spoonful of water about every two or three hours during the first four days, but large nutrient enemata of peptonized milk, beef tea, etc., were given three times a day. The entire wound healed by first intention. I removed the stitches on the fifth day. The patient *got up on the tenth day* and was discharged from medical attendance on the fourteenth day. The photograph, from which fig. 1 is copied, was taken on December 6th, nineteen days after the operation. The patient is as well in every respect as he was previous to the accident.

The table which precedes shows that *only ten cases of gastrotomy are recorded* in the history of surgery, which can be compared to the one just described. We must exclude, from comparison with our own, all cases where adhesions had been formed between the stomach and the abdominal walls. In the latter cases, the operation of gastrotomy loses its dangerous features and becomes an operation of little more importance than the opening of an abscess. Including these latter cases, there are twenty-six cases of gastrotomy on record with four deaths. Seven of these, however, are so imperfectly described by the authors that they must be discarded from all tables which lay claim to our consideration for scientific purposes.

The above table requires but little explanation. The facts speak for themselves. The operation shows a surprisingly small number of deaths, the mortality being only eighteen per cent. All the cases have peculiarities, only two are nearly alike, they are the cases of Billroth and Credé. In both of these a set of false teeth was swallowed by the patients while asleep. The lives of both patients were saved by the operation of gastrotomy. This should be a warning for all those who wear artificial dentures, to remove them before retiring.

The distinguishing feature of my own case is: Firstly, the prompt manner in which the operation was performed, the knife having remained in the stomach only about one hour. Secondly, the knife which I removed seems to have been the longest object, which has been successfully removed from the stomach by gastrotomy. Thirdly, there are some minor peculiarities in regard to the method of suture and the employment of antiseptics, which differ from former cases.

[Written for the MEDICAL BRIEF.]

Post-Partum Hemorrhage and Its Treatment.

BY M. CLAYTON THRUSH, PH. M., M. D.,

Demonstrator of Pharmacy, Materia Medica and Prescription Dispensing and Instructor in Therapeutics, Medico-Chirurgical College. Philadelphia, Pa.

Hemorrhage during, or shortly after the third stage of labor, is one of the most trying and dangerous accidents connected with parturition. Its sudden and unexpected occurrence just after the labor appears to be happily terminated, and its alarming effects on the patient, who is often placed in the utmost danger in a few moments, tax the presence of mind and the resources of the practitioner to the utmost, and render it an imperative duty on every one who practices midwifery to make himself thoroughly acquainted with its causes and the preventive and curative treatment.

There is no emergency in obstetrics which leaves less time for reflection and consultation, and the life of the patient will often depend on the prompt and immediate action of the medical attendant. Every one has heard of cases, if he has not had them in his own experience, where, an otherwise normal labor, suddenly terminated with the death of the mother, and this often occurs at the very time it is least expected, and it occurs among the most skillful obstetricians, as well as the practitioner of the average ability. It is one of the most frequent complications of pregnancy, and it is especially common among the upper ranks of society. This is probably due to the effects of civilization and the mode of life of patients of that class whose whole surroundings tend to produce a lax habit of body, which favors uterine inertia, the principal cause of *post-partum* hemorrhage.

The report of the British Registrar General for five years showed three thousand five hundred and twenty-four deaths due to this cause.

Fortunately it is, to a great extent, a preventable accident. It is a curious fact that *post-partum* hemorrhage is much more common in the practice of some medical men than others.

Etiology.—(*a*) *Uterine Inertia:* One of the most common causes is irregular or incomplete contraction of the uterus, following the expulsion of the placenta, and, as a result, there is incomplete closure of the venous sinuses, which are destitute of valves, and if contraction be absent, partial or irregular, it is easy to understand why blood should pour forth in the appalling amount which is sometimes observed. Uterine inertia is often caused by exhaustion following protracted labor.

(*b*) *Extensive laceration of the cervix.*—This condition may be present from this or previous labors, and blood may escape, even if the uterus is satisfactorily contracted.

(*c*) *Over-distention of uterus.*—This is observed when there has been an excessive amount of liquor amnii, or in multiple pregnancies.

(*d*) *Rapid delivery.*—Rapid emptying of the uterus during which there has not been sufficient time for complete separation of the placenta, often tends to the same result. This explains the frequency of hemorrhage following forceps delivery and "precipitate labors."

(*e*) *General condition of the patient.*—The general condition may strongly predispose to it. Then it is more often observed in women who have borne families, especially if they are in a weak and debilitated state, and it is comparatively rare in primipara.

(*f*) *Climate.*—Climate is also a factor, and women debilitated by the relaxing effects of warm climates, are peculiarly prone to it, as is proven by the experience of practitioners in the tropics.

(*g*) *Partial or irregular contraction.*—Another important cause is partial and irregular contraction of the uterus, as "hour-glass" contraction, due to spasmodic contraction of the internal os uteri, by means of which the placenta becomes encysted in the upper portion of the uterus, which is relaxed.

(*h*) *Placental Adhesions.*—These are sometimes a causative factor, and the direct cause of these adhesions is often obscure, but it most probably results from a morbid state of the decidua, which is produced by antecedent disease of the uterine mucous membrane.

(*i*) *"Flooders."* — There are some women who deserve this appellation, as they have the most extraordinary tendency to hemorrhage after labor; do what you may to prevent it.

(*j*) *Malpositions of placenta.*—Such as is observed in partial placenta previa, or where placenta is abnormally low, and near os uteri.

Time of Hemorrhage.—The loss of blood may commence immediately after the birth of the child, before the expulsion of the placenta, or not until some time afterward, when the contracted uterus has relaxed. It may commence gradually or suddenly. There are few sights more appalling to witness than one of the worst cases of *post-partum* hemorrhage.

Treatment.—This can be conveniently divided into preventive and curative. The preventive treatment of *post-partum* hemorrhage should be carefully practiced in every case of labor. If the practitioner makes it a rule to have his attendant

place the hand over the contracting uterus, immediately after the expulsion of the child, until he separates the cord, and then he himself grasps the uterus and holds it, he will find few cases in which the placenta will not be expelled within ten minutes after the birth of the child, and but few cases of *post-partum* hemorrhage will be experienced.

Where there is a known predisposition to hemorrhage, small doses of ergot with strychnine, or other agents, as calcium chloride, or the active principle of the suprarenal glands are often of value, regulating dosage as indicated.

Curative treatment.—As there are only two means which nature adopts in the prevention of *post-partum* hemorrhage, so the remedial measures may also be divided into two classes: (1) those which act by the production of uterine contraction; (2) those which act by producing thrombosis in the vessels. The first are generally used, and the second only resorted to in the worst cases.

Administer ergot or the active principle of the suprarenal gland, hypodermically, in conjunction with diffusible stimulants, such as brandy and ether, according to the condition of the pulse. Bimanual pressure of the uterus should be resorted to at once, and all clots pressed out, and the uterus kneaded to stimulate contraction, keeping it between the two hands all the time. If there is considerable loss of blood, the injection of normal saline solution, either alone or combined with the active principle of the suprarenal gland, is of great value, either by hypodermoclysis, enteroclysis, or intravenous injection, as indicated. The introduction of various agents into the uterus is often of value. Use ice or ice-cold water, or hot water (100° to 120° F.), either alone or with some agent, as the compound solution of cresol, the active principle of the suprarenal gland, or some iron salt in solution. Packing the uterus with gauze or cotton is often of the greatest value.

Electricity, in the faradic current, is often useful. Finally the injection, or application of powerful styptics, such as ferric chlorid or sub-sulphate, matice, iodine and vinegar or acetic acid is often necessary in order to arrest the bleeding.

In conclusion, the following case will illustrate the treatment employed in a severe case of *post-partum* hemorrhage, with recovery:

Mrs. R., age twenty-eight, housewife: Gave birth to healthy child two years ago. This was her first child, and labor was normal, except forceps were required owing to the large child. When sent for, found her in active labor, with cervix dilated, and delivered a normal child, followed in five minutes by placenta, and everything entirely satisfactory. Patient was lying on her back, and, without the slightest warning, about five minutes later there was a terrific gush of blood, which fairly streamed from the vagina, and in a few seconds, before I could introduce my hand to make compression, she was almost in a state of collapse. Notwithstanding manipulation, with resultant contraction of uterus, the hemorrhage abated but slightly, and I at once packed the uterus solid with cotton and gauze at the vaginal outlet, with good and tight binder later over abdomen, after hemorrhage was controlled. By this time patient was blanched, and almost exsanguinated. Administered diffusible stimulants; brandy and strychnine, hypodermically, with ergot, then strong coffee, by mouth and external heat, and patient gradually reacted, when saline solution was given by rectum, and the following combination internally, with excellent results. Cotton tampon was removed next morning.

℞ Calcii Chloridi..... 5 grains.
Sol. (1:1000) of active principle of Suprarenal Glands.....20 minims.
Fluid Ext. Ergot..... ½ drachm.
Elix. Aromat.....q. s. ad..... 1 drachm.

M. Sig.: This dose was administered every two hours for three doses, then every four hours for two days.

[Written for the MEDICAL BRIEF.]

The Needs and Uses of Eye Glasses.

BY W. WHITEHEAD GILFILLAN, M. D.,
Oculist to the City Hospital, French Hospital, Sailors' Snug Harbor, and to the House of Refuge; Consulting Oculist to St. Vincent's Hospital, Staten Island, New York City.

It is not my idea to go very deeply into the subject of refraction or ordering of glasses. This is a subject of which, perhaps, the general medical man knows less of than any other department of medi-

cine; and justly so, too, when one considers the eye to be a special subject by itself. There is probably no other branch of medicine which has been, and is recognized today to be more of a special subject by itself, than diseases of the eye. The work of the specialist in this line is made up largely of testing for refractive errors of patients. In fact, three-quarters of all our work is of this nature. The other quarter is made up of treating external eye diseases, ophthalmoscopic work and operations.

The men who graduate from our large medical schools today have been instructed in a general way in this branch of medicine, as they have been in other special lines. How different this is from twenty years ago, when a man knew nothing about special subjects at graduating. He was busy enough in his two years' course without them.

Refraction, to many, is a very dry subject, and it is not my purpose to bore you with details. It is an exact science so different from many other departments of medicine. The theory of it is quite different from the practical application of it, and there are a number of practical applications of one theory. A man may know the science of refraction from the book very well, but the practical application of it is quite a different thing. To my mind it takes between three to six months, working daily with cases, for a man to become proficient in it.

Probably many of you have test cards in your offices to test a patient's sight roughly. These test types have been found on the examination of many thousands of eyes, to form a standard of sight. The top, or largest letter, which is about the width of the finger, should be seen at a distance of two hundred feet by the normal eye. The usual distance to place the card from the patient is twenty feet; for the sake of convenience, of course, it may be placed closer, if there is not more space, say ten feet. In reporting cases it is usual, however, to have tested at twenty feet, and for that reason we use that distance for testing, when possible. Each line of letters on the card is numbered, as, for instance, the top, two hundred, means, as I have said, should be seen at two hundred feet from the eye. The second line of two letters, is one hundred; meaning it should be seen at one hundred feet away. The third, seventy; the fourth, fifty; then forty, thirty and twenty.

In testing a person for sight, we test the eyes separately by holding a card over one eye. If we did not do this we would not know if there was any difference in the vision of each eye. For instance, a person with one eye which could only read the top line, and the other eye read all the lines of letters, the result in testing both eyes together would be that the patient would read every letter on the card, and one would not know that one eye was so defective.

In this case one eye, the right, we will say, sees only the top letter, the other all; we would make a record that the vision of the right eye was 20/200, or 20/200 of what it ought to see, while the vision of the left is 20/20, or normal sight. If an eye can see the letters on the second line and letters below, we record the vision as 20/100. In the same manner, if an eye can read the sixth line, down which is marked thirty, it would be recorded as 20/30.

If we were testing at a distance of only ten feet, we would write it 10/200, if the eye could only see the top letter. If an eye is so defective in vision that it can not see the top letter at twenty feet, we bring the card closer until it can be seen, say, at five feet. We would then write the vision as 5/200. A better plan is to use the fingers, since they are the same size as the top letters. That is, hold them out in front of one and walk towards the patient until they can tell the number that are held up. The advantage is the number of fingers can be quickly changed and the patient can not fool you as they can with a card, particularly when they know the top letter.

The reasons why a person presents themselves to an oculist for examination for refractive error is usually one of two reasons. Either they do not see well or they have headache, or pain in the eyeball. The first thing we do when a person is to be examined for glasses is to test the vision. Many people complain of headaches, and particularly pain right over the eyes when they engage in any

close work, such as reading, writing, etc. Many of these cases, on examination, will show that the vision is very good; in fact, what we call normal, or 20/20. The trouble in these cases is the astigmatism, which is an uneven curvature of the front of the cornea. That is, one meridian, say the horizontal, is more curved than the other, the perpendicular.

For these cases a cylindrical glass is what is required to equalize things. A glass of this nature refracts only in one meridian. By wearing proper glasses these kind of cases are relieved of their headaches. It is not that the sight in these cases is improved very much, or even at all in some, but it relieves the eye strain to which the eye has been subjected. Astigmatism is supposed to be caused by the unequal pressure of the eyelids on the cornea. This is corneal astigmatism. We may also have astigmatism of the lens of the eye, which is not so common. It often is very surprising what splendid results are gotten by wearing a weak cylindrical glass in these astigmatic cases. A person may have suffered from the most severe frontal headaches, or pain in the back of the head, for a long time, and the vision is normal for distance, but, on examination with the ophthalmometer, we find astigmatism. After a few days' wearing of the proper glasses the headaches subside. It is most important for these people to wear the glasses straight. That is, so that the lenses are not tilted up or down. If they are on wrong, it is as bad as if no glasses were worn. They are sure to have their headaches then, and blame the glasses or oculist.

Other cases may be near-sighted (myopic), or far-sighted (hypermetropic). In near-sighted people the distant vision is apt to be very bad. With a concave spherical glass we can usually improve the sight very much. A patient may have vision in each eye of only 20/200, which, by proper correction, can be brought up to 20/20.

It is the custom in the examination of patients, after the vision is found, to use the ophthalmoscope. By it one is enabled to tell at once if it is near-sightedness or far-sightedness we have to deal with. More important, though, is to see if the eye be healthy. That is, that there is no diseased condition of the inner coats of the eye, the chorioid and retina and the optic nerve.

This nerve is the only one in the body that may be inspected. Eliminating any diseased conditions we can proceed to the test-glasses. About the test-glasses I need not burden you.

Of what I have told you about using the ophthalmoscope is where the difference comes in between the oculist and optician. A person may come to an oculist thinking their sight is bad, and due to some refractive error which can be corrected by proper glasses. The oculist discovers something much more important—the cause, such as choroiditis, retinitis, cataract, atrophy of the optic nerve, or glaucoma. It may be that the person has come in time so that something can be done to relieve matters. The oculist does not have to order glasses for every person that comes into his office. With the optician it is different. A person calls on him and he tests the distant vision, and finds it 20/100, we will say. He uses all kinds of glasses, and at last orders something—possibly a strong magnifying glass—anything to make a sale. Perhaps the person has glaucoma, and in the course of a few days, goes blind. In a short time there will be no hope of restoring sight unless something is done in the way of an operation. Of course, these things do not happen very often, but we, as oculists, see all the bad cases that have been neglected.

There is a bill in the Legislature now to license opticians, so that they may have a standing almost equal to oculists. When a person stops and thinks that an oculist is a graduate of medicine, and has studied four years, and then takes up the eye as a special subject afterwards, it seems strange he should be classed with any one who sells eye-glasses. The relation between the oculist and optician should be the same as between the physician and druggist.

People who get to be forty-five years old, and have never had any trouble with their eyes, find that in the evening, when reading, their eyes get tired, and they become sleepy. The book has to be held a little farther off to see the letters. This condition is what is called presbyopia, or

old sight. The vision for distance may be normal, or 20/20. What is needed is a convex glass which will magnify. The condition of presbyopia is physiological, and not pathological. The muscles which move the lens so as to make the focus for reading distance lose their power. Their place is supplied by the glass. It is necessary always to test a person first for distance to see if they are far-sighted. If they are, the far-sighted glass is added to what may be needed for reading. That is, a person who is not either near-sighted or far-sighted at forty-five will require a +1D glass to read with. If they were far-sighted, say +2D, they would need a +3 to read with. If a person were near-sighted, say —2D, the condition is different. A —1D glass, held against a +1D glass, neutralizes each other, and makes a plain piece of window glass. The person, then, at forty-five, who uses —2D for distance, needs only a —1D to do near work with, and at fifty years needs no glasses at all for close work. Every five years from forty-five on a +1D is required for reading distance. At fifty-five this same person would still be using the —2D for distance and +1D for near.

We come across people eighty or ninety years old who say they never use glasses, and see as well as ever for distance and near. This is easily explained. One eye, we will say the right, is neither far-sighted or near-sighted, and the vision good for distance. The other, or left, is near-sighted, and is used for near work. Of course, these two eyes never can focus together. Take, for example, a man aged thirty-five who has vision of 20/70 in the right eye and 20/100 in the left. The right eye is far-sighted, we will say (+2D), and with that glass brings up the vision to 20/20. The left is myopic —3D. The focus of the eyes is so different that a — glass and a + glass can not be worn with comfort at the same time. It gives one a headache. What we do is to order a + glass for the right and a piece of window glass for the left. At the age of fifty-five he may read without any glasses at all.

Almost any one can wear glasses if they wish to. Very few people have perfect sight from a scientific standpoint. A person may have vision of 20/70 in one eye and 20/50 in the other, and for the kind of employment they are engaged in, it is quite enough, perhaps. There would be little use in putting on glasses and making the vision 20/20, particularly if they have no headaches.

A friend of mine, an oculist, is making an examination of all the eyes of the school children of Tuxedo. Of the one hundred and fifty he has so far examined, he finds one-third with defective vision, and quite a number who read 20/20, but who have eye-strain. It does not seem to me that all of these children require glasses, although many oculists would say they did. A child might have vision of 20/40 in one eye and 20/50 in the other, and still be bright, and learn quickly, and have no head symptoms. Such a case does not require glasses. Most of the cases who had 20/20 vision, and had the head symptoms, would require glasses. Most of these cases are astigmatism. When a person has astigmatic troubles it is not necessary to wear glasses all the time. To use them for close work may be enough. If, however, the headaches continue when a person is walking or sitting around the house it will be necessary to make constant use of them. In other words, any time a person has headaches, wear the glasses. The amount of astigmatism often changes, and sometimes very quickly—that is, in a few months. It may get less or increase. Of course, this change is due to change of contour of the cornea. For this reason a person might have headaches six months after getting glasses and wearing them all the time properly. The change in the cornea would explain the whole trouble.

Of course, a person may be far-sighted or near-sighted and have astigmatism also. In these conditions we correct both with a combination glass of cylindrical and spherical. It has to be ground especially for the case. This kind of glass is much more expensive than a plain cylinder or spherical, which an optician has always in stock.

There is a proposition now before the Board of Education of the city to have all school children's eyes examined for refractive errors, and glasses to be supplied when the parents are too poor to pay for them. It is estimated that there

are sixty thousand children who require glasses. It is a good thing to have glasses when needed, but most of us, I think, are opposed to having the city give away glasses. The best way is to have the children supplied through some hospital or dispensary by private charity, the way it is done at present. Most dispensaries and hospitals have a fund to supply glasses for those too poor to pay.

I have not spoken about the use of cycloplegics or drugs used to paralyze the accommodation in testing for refractive errors. At the present time I hardly ever use them, as I believe, after a long trial of atropine and other drugs, that we get better results without their use. Many men do use them, and swear by their use. The mydriatics usually employed are atropine and homatropine. Cocaine is not used, because it does not completely paralyze accommodation. In London the rule is to use atropine on every refractive patient from fifteen to twenty-five years old. From twenty-five to forty, homatropine. The great objection to the use of these drugs is that it keeps a person away from employment, as they can not use their eyes for close work. It takes a week to ten days for the paralysis of accommodation by atropine to wear away. In homatropine two to three days. The objection to homatropine is that it does not always completely paralyze accommodation.

For instance, a person has vision of 20/20 in each eye, but has headaches. After a four-grain to the ounce solution of sulphate of atropine has been instilled in each eye, drop t. i. d., for one day, the vision is 20/50. By the ophthalmoscope we may find three-fourths of a D of hypermetropia, which, of course, will not be accepted by the patient after the effects of the atropine have worn off. The ophthalmometer is one of the oculist's most valuable instruments. It tells the amount of the corneal astigmatism and the axis of it, which is most important. In a case like this it saves us much trouble, as it lets us know if there is any astigmatic trouble or not. Let us suppose that a patient's vision has only 20/200 after using atropine, and we tested and found no astigmatic trouble, but with a +2½D glass the vision was brought up to 20/40. We would not think of ordering the +2½D glass, but wait until the effects of the mydriatic has worn off. We test again, and find only +1D glass accepted. We order this. Of course, by using the atropine we have found out the total amount of refraction, but the patient will not accept all, as the action of the ciliary muscle prevents this. Only the manifest hypermetropia is corrected, not the latent also. What is the use, then, of using atropine if one gets good results without it? As I showed, we order what the patient accepts after atropine wears off. Why not do it at first? I belong to the school that does.

Of course, people who have had cataracts removed require glasses to see. The lens which is removed has a magnifying power of +9D, usually. If the patient has been wearing +3D glasses before the cataract developed, we add this to the +9D, which would be +12D glass which was needed.

I have recently operated on a patient who, before the cataract developed, wore a —9 D glass. Since the operation no glasses are needed. As +9 and —9D, held together, neutralize matters.

I have only tried in a very slight way to touch on a few points on refraction. If I have made some matters about wearing glasses clear I am glad.

A New Ligature Carrier.

BY ELLERY M. HETHERINGTON, M. D.,
Professor of Diseases of Women and Obstetrics in the University of Kansas.
Kansas City, Mo.

This needle is designed to take the place of the Cleveland needle, and differs from the latter in the following respects:

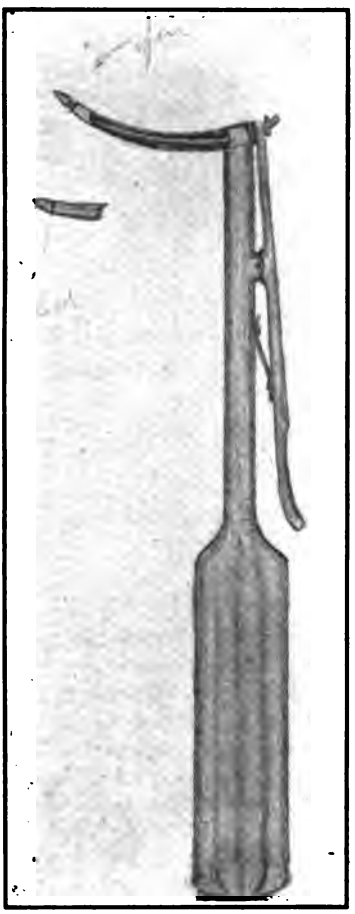
It is not necessary to spread this needle in order to thread it, thus avoiding the possible laceration of tissues through which it passes.

It can be threaded either before puncture or after, and the thread withdrawn with the needle, the same as in the Cleveland needle.

A little spring underneath keeps the needle's eye always open, and which per-

mits the entrance of the ligature without the aid of vision. Then very slight pressure made upon the thread handle presses the thread between two square shoulders, and grasps it very firmly; by releasing the handle the ligature falls of its own accord over the needle, or the ligature is released from the needle automatically.

This needle is nothing more nor less in structure than the trocar and cannula,



the trocar having a head with a small bar passing up through the cannula, which forms a notch in the end of the needle.

The instrument can be made perfectly aseptic by removing the two little thumbscrews.

The inventor has used this needle several times, and has found it absolutely satisfactory.

Its greatest utility is for the passing of sutures through deep structures in the abdominal cavity, where it is impossible to raise the tissues high enough to see the point of the needle to throw the thread or release it. By the guidance of the finger with the needle closed, it can be gently pressed through any tissue, and the handle released, when the needle will open and the ligature be carried down over the end of the finger until you reach the shaft of the needle, when, by sliding the ligature along toward the point of the needle going to the notch, it will follow it, and pressure can then be made upon the handle, and the ligature is caught firmly.

On the other hand, if the needle is removed with the ligature before making a puncture, the ligature can be caught with a pair of forceps, or with the finger in the same manner as it was threaded in the other instance.

If one desires to use the "cobbler's stitch" in the broad ligament, or in any other tissue, one end can be carried through, and the other end threaded and drawn back, just as the shoemaker uses the double waxed end. Or if you wish to increase the utility of the "cobbler's stitch" by making continuous interrupted ligature, it can be done in the manner already referred to by the addition of tying your end before threading the needle to withdraw. The same end can be carried back through the same opening, and the second end tied, and so on from one to another, so that a continuous interrupted ligature can be made with any number of ligatures desired.

A Few Notes on Diagnosis of Injuries of the Extremities.

BY B. D. MATCHAN, M. D.,
Senior Professor of Surgery in the Homeopathic Medical College of the University of Minnesota.
Minneapolis, Minn.

One of the most important surgical subjects to the general practitioner is the accurate diagnosis of injuries to the extremities, as, for instance, dislocations and fractures. I do not believe there is another surgical subject which comes

within the scope of the average practitioner where there is more responsibility.

In order to be accurate in our diagnosis, comparatively accurate, it is necessary that we should become thoroughly familiar with the anatomical landmarks. Landmarks always bear the same positive anatomical relations to each other.

For example: When normal, the olecranon process always bears the same positive relation to the condyles of the humerus. The acromion process bears the same relation to the head of the humerus.

We appreciate when the swelling of the joint is great and there is marked tenderness that it becomes difficult, and sometimes almost impossible, to locate definitely the landmarks. Under those circumstances an anesthetic, of course, is necessary. Landmarks once located, if they bear the same relation with the corresponding landmarks on the opposite extremity, viz.: normal, there can be no displacement of the articulating surfaces entering into the formation of that particular joint, hence dislocation is eliminated.

In fractures, I believe the three most important symptoms are: First, deformity; second, loss of function, and third, a distinctive diagnostic feature which I have found of great value, enabling me many times to make a diagnosis which otherwise might be difficult, is the much impaired or lost sense of transmission of the bone. For example, grasping the suspected injured bone by either extremity; if there is no solution of continuity any manipulation made at one extremity is transmitted directly to the other extremity. If there is solution of continuity it is very much impaired, or entirely lost.

Deformities in surgery mean something more than the name implies. It may be swelling, infiltration, or any deviation from the normal. In cases of fracture deformity means either shortening or deviation of the bone from its normal axis.

Solution of continuity means loss of function.

There is one other symptom always considered very important, yet I think overestimated, because many times it has been impossible to elicit it, viz.: crepitus.

Even in fractures the landmarks become a very important factor in our diagnosis. For instance, in a broken femur, if the distance from one superior spine of the ilium to the inner malleolus is the same on the injured leg as on the opposite one, there is at least no shortening. If there is no deviation in the long axis of the suspected bone, there can be no displacement of the fragments. Yet it is possible under these circumstances to have a tranverse fracture, but if any manipulation that is made at the knee is transmitted directly to the greater trochanter there is no fracture of the shaft.

Hence, a correct knowledge of landmarks, and the exercise of great care in examination, will save us many hours of anxiety, and possibly suits for malpractice.

Diseases of the Breast.

BY ALFRED DE ROULET, B. S., M. D.,

Chicago, Ill.

Formerly Professor of Surgery and Diseases of Women in the Medical Department of Trinity University.

IV. FIBRO-EPITHELIAL TUMORS.

Inasmuch as the mammary gland consists essentially of a conglomeration of epithelial-lined ducts, supported in a fine connective tissue reticulum, all new growths appearing in the breasts partake largely of the characteristics of both tissues. In one tumor the epithelial elements predominate, while in another the connective tissue is more in evidence. A tumor originating in the periductal connective tissue inevitably involves the epithelium of the ducts, while an epithelial tumor, unless it be carcinomatous, can not develop in the breast without including in its structure a considerable quantity of connective tissue. On account of this intimate relationship between the epithelial and the connective tissues, it would seem almost impossible for a pure fibroma, or a pure adenoma to develop in the breast. The efforts of the early surgeons and pathologists to classify breast-

tumors in accordance with the nomenclature applicable to new growths in other organs, resulted in the most hopeless confusion. The first effective effort to bring order out of chaos was made by Ribbert, when, in his classification, he suggested a special group of "fibro-epithelial tumors." Warren has still further simplified matters by defining and restricting the use of the term, and by harmonizing the clinical aspects of the fibro-epithelial tumors with their pathological nomenclature.

included therein by the extending periductal tissues. The fibrous tumors are classified according to the character of the fibrous growth, and the degree of cellular development, into three groups: (*a*) periductal fibroma, (*b*) periductal myxoma, and (*c*) periductal sarcoma. Personally, I am inclined to consider the periductal myxoma an unnecessary refinement of differentiation. These tumors not only occur very infrequently, but such as come under observation are often distinguished with the greatest difficulty from

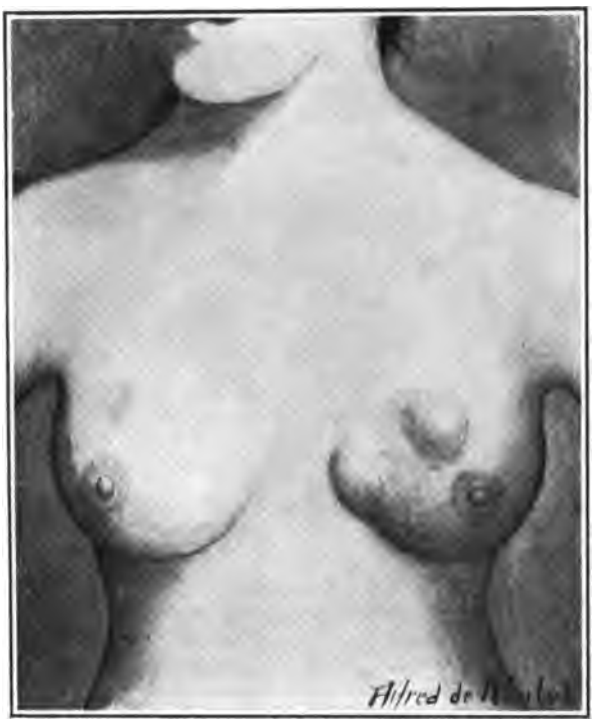

FIG. 1. Periductal Fibromata of Breast.

In Warren's classification these tumors are divided into two distinct groups. (1) the fibrous, and (2) the epithelial, according as the fibrous or the epithelial elements predominate.

The tumors of the fibrous type arise from the periductal connective tissue of the breast, and consist essentially of this tissue, although they contain, more or less incidentally, certain portions of the epithelial structures of the gland, such as distorted ducts and epithelial-lined clefts. These structures do not form an integral constituent of the tumor, but are simply the fibromata on the one hand, or periductal sarcomata on the other.

Periductal Fibroma.—This type of tumor is of comparatively frequent occurrence, comprising rather less than ten per cent of all tumors of the breast, and approximately fifty per cent of all tumors appearing in the breast before the thirtieth year. They are found most commonly in the breasts of women of from twenty to thirty years of age, and rather more frequently in those who are sterile than in those who are prolific. The size of the tumor varies from

that of a filbert to that of an orange, the average being about the size of an English walnut. The tumors are of slow growth, and painless, and may be single or multiple; as a rule, they are found at the periphery, rather than in the central portion of the breast, and are superficial, rather than deep-seated. Not infrequently both breasts are involved. The individual tumor is smooth, rounded, hard, elastic, and freely movable in the breast substance. It does not infiltrate the surrounding tissues; it does not become adherent to the skin; it causes no enlargement of the axillary or supra-clavicular lymphatics, and gives rise to no constitutional symptoms. On section it appears as firmly encapsulated tumor, of a glistening whitish appearance, the cut surface being traversed by numerous irregular fissures and clefts, while cyst formation to a variable extent is occasionally observed.

Periductal Myxoma.—The periductal myxoma are of very infrequent occurrence, and is said to appear somewhat later in life than the periductal fibroma; that is, from the twentieth to the forty-fifth years. As a rule it is somewhat larger than the fibromata, and is of considerably slower growth, although in isolated cases the growth is comparatively rapid. The tumors may be single or multiple, and one or both breasts may be involved. The individual tumor is smooth, rounded, and imparts to the fingers a sensation somewhat resembling that of a slightly wilted potato. The smaller tumors are freely movable in the brea but with the larger tumors the degree mobility is greatly diminished, and adl sions to or ulcerations of the skin a likely to develop, as the result of pressu The axillary glands may become enlarg although such enlargement is by means characteristic of this conditi Pathologically it does not differ appre ably from the periductal fibroma. On s tion it presents a homogenous, ser transparent, whitish stroma containi irregular clefts and cyst cavities.

Periductal Sarcoma.—This tumor is f tunately, quite rare; occurring in appr imately one-half of one per cent of breast tumors. They are found most f quently in the breasts of women of fr

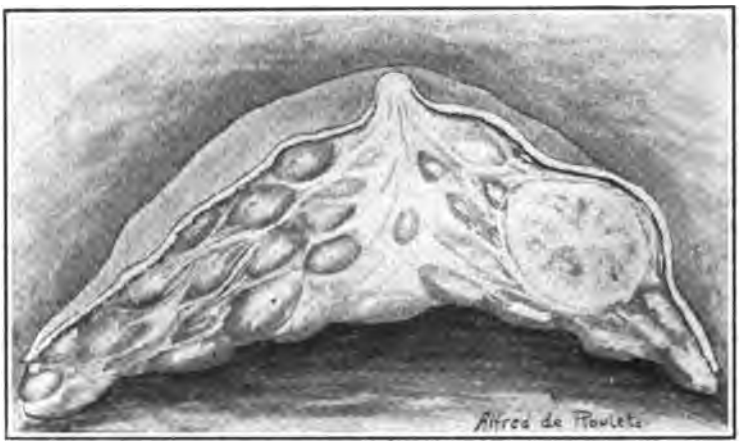

Fig. 2. Section of Breast Showing Periductal Fibroma.

forty to sixty years of age. They devel slowly, and without any appreciable pa and may attain a size ranging from th of an orange to that of a child's he The skin overlying the tumor is usua reddened, but is not necessarily adhere or ulcerated, although there is a stro tendency toward ulceration. The sup ficial veins of the breast are often grea distended. The axillary lymphatics a not usually affected.

The tumor itself is large, hard, lob lated, and surrounded by a very we defined capsule. A large portion, if n the entire breast, is usually involv Pathologically, the periductal sarcoma merely an exaggeration of the periduc fibroma or myxoma, the periductal co nective tissue being so rich in cells as

warrant classification as sarcoma. The relationship between the tumors is very close, and it is very seldom that a periductal sarcoma is found which does not present, in some portion, a typical picture of fibroma. Clinically, the periductal sarcomata are characterized by a comparatively moderate degree of malignancy, and the disturbances which they cause are likely to be more or less local in character.

In a certain proportion of the fibro-epithelial tumors of the breast, the epithelial formation completely overshadows the growth of the periductal tissue, the connective tissue simply constituting a support for the epithelial new growth. Tumors of the type, the cyst adenomata, occur as two distinct varieties, described by Warren: (1) fibro-cystadenomata, and (2) papillary cystadenomata.

The fibro-cystadenoma resembles the periductal fibroma very closely, the clinical findings are almost identical, the growth develops slowly, and without appreciable pain, and occurs most frequently in the periphery of the breasts of women from twenty-five to thirty-five years of age. The tumor itself may be single or multiple, and may range from the size of an almond to that of an orange. It is hard, rounded, elastic and freely movable; does not become adherent, and causes neither dimpling or discoloration of the overlying skin. The nipple is not retracted, and the axillary lymphatics are not affected. On section, the tumor presents a distinct capsule, and a more or less lobular structure, the stroma is white and glistening, but the fissures and clefts are rather more numerous than in the periductal fibroma, otherwise the appearances are almost identical. Microscopically, there is shown decided proliferation of the epithelial cells lining the clefts and cyst cavities.

The Papillary cystadenoma is of comparatively frequent occurrence, and undoubtedly presents the clearest and most characteristic clinical picture of any of the benign tumors of the breast. The tumors may be single or multiple, but unlike the tumors of the fibrous type, are found in the central, rather than the peripheral portion of the breast. They occur most commonly in the breasts of women from forty to sixty years of age, and especially those who have reared large families. The tumor may be so small as to be almost imperceptible on palpation, or it may be so large that it involves the entire breast. On palpation the small tumors feel hard, and more or less rounded; the larger ones may be elastic, or even fluctuating. The growth is slow, and in approximately one-half of all cases is accompanied by a degree of pain sufficient to attract the patient's attention, but not sufficient to cause any particular suffering. The most characteristic symptom is the presence of a serous or sero-sanguineous discharge from the nipple, this symptom being present in from sixty to seventy per cent of all cases. Not infrequently it is the appearance of this discharge which first attracts the attention of the patient to the developing tumor. As a matter of course

FIG. 3. Microscopic Section of Periductal Fibroma.

the presence of the discharge depends upon the patency of the duct leading from the cyst to the nipple. When the duct is patulous pressure over the tumor causes a partial evacuation of the cyst contents, and consequently a certain diminution in the size of the tumor.

On section a papillary cyst adenoma is found to be encapsulated, and to contain one or more cyst cavities, the cavities being filled to a greater or less degree by villous or papillary projections from the cyst walls, the fluid contained being serous or sero-sanguineous in character.

Microscopically, these outgrowths present a vascular, branching, fibrous tissue stalk

supporting a luxuriant growth of epithelial cells, the cells presenting the characteristics of ductal, rather than acinal epithelium. Under ordinary circumstances this epithelium shows no tendency to infiltrate surrounding tissues.

The clinical diagnosis is based on the location of the tumor near the nipple, the slow growth, the comparative absence of pain, the presence of the serous, or bloody discharge, together with the absence of axillary enlargement, retraction of the nipple or adhesions to the skin. The condition may be confused with periductal tumors, atypical parenchymatous hypertrophy and cancer. The periductal tumors occur in younger women; are more movable in the tissues, are peripheral, rather than central in location, are hard and elastic, and never cause a discharge from the nipple. A fibro-cystadenoma might readily be mistaken for periductal fibroma, and, to be perfectly frank, in many cases it would be impossible to make a positive differentiation without a microscopic examination.

FIG. 4. Papillary Cystadenoma of Breast.

As regards the prognosis in fibro-epithelial tumors of the breast, the tumors of the fibrous type show a decided tendency to sarcomatous change, while the tumors of the epithelial type show an even more marked tendency to carcinomatous degeneration. The percentage of the fibrous tumors undergoing malignant degeneration is as yet undetermined, but from data at hand I am inclined to believe that approximately ten per cent undergo such changes. Of the tumors of the epithelial type carcinoma develops in rather more than fifteen per cent of all cases.

Folds, Bags and Wrinkles of the Skin About the Eyes and Their Eradication by Simple Surgical Methods.

BY CHARLES C. MILLER M. D., AND FLORENCE MILLER, M. D.,
Chicago, Ill.

Folds and wrinkles frequently develop prematurely about the eyes of individuals, adding years to the apparent age. Bagging of the skin beneath the eyes not only adds somewhat to the appearance of age, but revolts sensitive people so that unfortunates so afflicted earnestly desire relief, if such is obtainable.

These conditions may be easily overcome by simple surgical procedures, which are performed painlessly with the aid of infiltration anesthesia. Results have invariably been good in my hands, and I see no reason to fear untoward consequences from the operations I practice. Preparations for these operations are simple. Any physician may equip his office so that he can do this work satisfactorily, and the technic calls only for ordinary surgical dexterity.

A hypodermic syringe, a keen scalpel, small, sharp scissors, fine cambric needles and fine sterile silk represent the instruments absolutely necessary for the operations.

Cleanliness is essential to prompt and satisfactory healing. The face of the patient and the hands of the operator should be scrubbed. Antiseptics may be used, though they are not essential.

These operations are painlessly performed after the tissues have been infiltrated with a weak cocain solution. By painlessly, I do not mean that the patient is hanging on to the table with both hands and praying for the early conclusion of the ordeal. The most nervous woman will quietly admit, during the operation, that she is suffering from no pain whatever.

Distention of the tissues with fluids produces insensibility to pain, but the injection of but few solutions will prove painless. A great deal of nonsense has been written about sterile water. I do not deny that sterile water will produce an absolute insensibility to pain. We have all known this for a good many years, but the injection of sterile water under ordinary circumstances is not a painless procedure. As a rule the injection of sterile water produces considerable discomfort. To obviate this a trace of cocain is added to the sterile water, and then the injection is painless after the needle has been coaxed into the skin.

For the operations under consideration about one-half an ounce of infiltrating solution is needed. I am in the habit of making up about twice as much as I expect to use. An ounce of boiled water should be taken under these circumstances, and one-fourth of a grain of cocain added to it. Cocain may be secured in tablet form for the purpose of making these solutions conveniently.

A hypodermic syringe which permits of sterilization answers very well for infiltrating, although I have, for the sake of convenience, syringes holding one, two and four drachms.

The infiltration technic is very simple. The needle of the syringe is coaxed into the skin, and a drop or two of the cocain solution deposited. The needle point is now pushed further into the tissues, and more fluid deposited. At the point of insertion of the needle sufficient solution should be deposited to cause a pallor of the skin. This will insure a painless reinsertion of the needle. The operator distends the tissues somewhat beyond the proposed lines of the operation, and distends the tissues moderately, testing the skin with the point of his needle to ascertain as to the sufficiency of the infiltration. If the skin is distended to the limit one is sure that the operation will be painless, but at the same time such extreme distention interferes with accurate judging as to the amount of tiss· which should be removed during the operation.

Wrinkles, folds and bags beneath the eyes are eradicated by the removal of a crescent of skin beneath the eye. The convexity of the crescent should be downward, and the concavity of the crescent should lie close to the lashes along the lower lid. The width of the crescent varies according to the depth of the wrinkles or the size of folds or bags. The first incision should be made with a sharp scalpel along the lid. The skin should be divided entirely, and loosened somewhat. It should then be drawn upward, the operator observing carefully just how much must be removed to entirely over-

Figure illustrates the line of incision in the operation below the eye. The crescent of skin is entirely removed. The size of the crescent varies according to the amount of bagging, folding or wrinkling of the skin. Above the eye the area of skin removed varies in shape, the operator simply picking up and cutting away the excess.

come the condition demanding the operation, then, with the scissors, the skin is cut away so that the crescent is made complete.

Just sufficient skin is left along the margin of the lid to permit the stitches being passed in closing. The line of union is brought in this way under the shadow of the lashes, and is entirely invisible.

Hemostasis should be complete before the skin intervals is closed. Bleeding is never troublesome in these cases. A few moments pressure with a small pad of sterile cotton will control it. Should the operator desire, the bleeding points may be twisted. Styptics are not needed. The approximation of the skin should be accurate. Continuous or interrupted stitching may be used according to the election of the operator. I use fine silk and fine cambric needles. Sutures should

not be tied tightly, as this favors cutting of the stitches so that stitch marks may be left.

The fold above the eye after infiltration is picked up and trimmed away. The line of closure here is at the upper extremity of the lid, so that the slight line of union is hidden in the fold between the lid and the brow, when the eye is open, and only shows slightly when the eye is closed. The proposition is a very simple one when operating above. The excess of tissue is cut away, and the skin margins of the interval accurately closed with sutures.

Dressing of these cases is somewhat important. Collodion dressings may be applied so as to remove all tension from the sutures; the sutures in such a case merely serving to insure accurate approximation of the skin margins.

A strip of cotton should be tucked under the lashes, and plastered securely to the skin with several coats of collodion. The collodion dressing is applicable above the eye as well as below.

70 State Street.

Evident Truths in Connection with the Science of Medicine.

BY J. MOUNT BLEYER, M. D., LL. D., F. R. A., M. S.

New York City.

In a field, wide as that of medical science, there are many paths, seemingly parallel in the outset, but ultimately converging toward those higher truths and more general laws, which, here as elsewhere, must be regarded as the just object and end of all research.

There can be few better tests of a sound understanding, than the right estimation of medical evidence; so various are the complexities it presents, so numerous the sources of error. The subjects of observation are those in which matter and mind are concurrently concerned; matter under the complex and subtle organization, when vitality and all its functions are derived. Mind, in its equally mysterious relations to the organs thus formed; both subject to numerous influences from without, both undergoing very various changes from disease within. Individualities of each have their effect in creating difficulties, and these amongst the most arduous which beset the path of the physician.*

Few cases occur strictly alike, even when the source of disorder is manifestly the same. Primary causes of disease are often wholly obscured by those of secondary kind. Organs remote from each other by place and function, are simultaneously disturbed. Translations of morbid action take place from one part to another. Nervous affections and sympathies often assume every character of real disease, while remedial agents are rendered uncertain in effect by the various forms of each disorder, by the idiosyncrasies of the patient, by the difficulty of securing their equal application or transmission into the system, and finally by the unequal quality of the remedies themselves.

These difficulties, the solution of which gives medicine its highest character as a science, can be adequately conceived by the medical artist alone. Neither those accustomed to legal evidence only, nor such as have pursued physical science in its more simple material forms, can rightly apprehend the vast difference made by the introduction of the principle of life; or, yet more, of the states and phenomena of mind, in connection with bodily organization. We have here a new world of relations, occult and complex in their nature, to be reasoned upon and resolved; with a principle of change, moreover, ever operating among them, and deviations from nature under the form of disease, which render all conclusions liable in a thousand ways to error. It is the want of this right understanding of medical evidence, which makes the mass of mankind so prone to be deceived by imposture of every kind; whether it be the idle fashion as to particular remedies, or the worse, because wider, deception of some system, professing to have attained at once, which the most learned and acute observers have labored for ages in vain.

It must be admitted, indeed, that this matter of medical testimony is too lightly

---

*Idiosyncrasy, as arising in most cases from inappreciable causes, is the most absolute and inevitable difficulty in medical evidence; since no accumulation of instances, such as might suffice for the removal of all other doubts, can secure us wholly against this source of error.

weighed by physicians themselves. Else whence the frequent description of effects and cures by agents put only once or twice upon trial; and the ready or eager belief given by those who, on other subjects, and even on the closely-related question of physiology, would instantly feel the insufficient nature of the proof.† Conclusions requiring for their authority a long average of cases, carefully selected and freed from the many chances of error or ambiguity, are often promulgated and received upon grounds barely sufficient to warrant a repetition of the trials which first suggested them. No science, unhappily, has abounded more in false statements and partial inferences; each usurping a place for the time in popular esteem; and each sanctioned by credulity, even where most dangerous in application to practice. During my years of practice of a quarter of a century, omitting all lesser instances, I have known the rise and decline of many fashions of medical doctrine or treatment; some of them affecting the name of systems, and all deriving too much support from credulity or other causes, even among medical men themselves.

Look at what is necessary, in strict reason, to attest the action and value of a new remedy or method of treatment. The identity or exact relation of the cases in which it is employed—a right estimate of the habits and temperament, moral as well as physical, of the subjects of experiment; allowance for the many modifications depending on dose, combination, quality of the medicine, and time of use;—due observation of the indirect or secondary, as well as direct effects;—and such observation applied, not to one organ or function alone, but to the many which constitute the material of life. All these things, and yet more, are essential to the completeness of the testimony. All can rarely, if ever, be reached; and hence the inevitable imperfections of medicine as a science. But much more, doubtless, of truth and beneficial result, might be attained, were these difficulties rightly appreciated, and the fit means obviating them kept more constantly in view.

In no class of human events is the reasoning of "*post hoc, propter hoc,*" so commonly applied, by the world at large, as in what relates to the symptoms and treatment of disease. In none is this judgment so frequently both erroneous and prejudicial. It would seem as if the very complexity of the conditions necessary to sound evidence, tended to beget acquiescence in that which is lightest and most insufficient for truth. The difficulties occuring in practice from this source are great, and require a right temper as well as understanding to obviate them.

Nor is there any subject upon which words and phrases, whether applied to disease or remedies, exercise a larger influence. Terms have descended to us, which we can hardly put aside;—maxims, which fetter the understanding and power of action;—and methods of classification, which prevent the better suggestions of a sound experience. And these are among the evils most aggravated by public opinion, ever prone to be governed by names, and particularly in all that concerns the symptoms and treatment of disease. The deeper the interest belonging to the subject, the greater the liability to error.

It needs to be called to the mind of medical men themselves how many organs of the body are still without a complete interpretation of their part in the animal economy. The uses of the ductless glands;—the spleen, thyroid, thymos and suprarenal bodies;—are yet only vaguely conjectured. The physiology of the brain and nervous system, then largely elucidated by the many fine researches of the past years, still abounds in difficulties, many of which time may overcome; while others are probably forever insuperable.

These are only a few instances indicative of one great source of error and embarrassment to which all medical proof is exposed. But in pathological doctrine, also, there is similar and equal difficulty from the character of the evidence concerned. It is only of late years that the improved power and refined use of the microscope has given us more assurance as to the nature and succession of these

† Amongst the other difficulties of evidence in such cases must be noticed the ambiguity of all language as applied to denote, and distinguish sensations; and evil familiar to every medical man, and only to be obviated by watchful experience.

changes; still leaving, however, various points open to future determination.

The history of contagious diseases furnishes another instance not less remarkable. It is the common belief of the world, and one plausible enough in its first aspect, that the laws of contagion are simple and readily learned. No mistake can be greater than this. All parts of the subject, even the circumstances most essential to practice, are wrapt up in doubt, and the evidence is of so intricate a kind, and so much disturbed by seeming exceptions, that the best judgments are perpetually at fault upon it. The same remark may be extended to other classes of disease, where time and the most acute observation have hitherto failed to extricate truth from the multitude of conditions present; but where, nevertheless, we have the certainty of relations hitherto undetermined, the fixing of which belongs to future research, and will well repay it in the result. The observations just made are not less true in relation to other departments of the science. Take the internal remedies. We employ, even those most familiar, and seemingly simplest in use. The difficulties already noticed as belonging to the evidence of their effects, extend yet further, and more remarkably, to the theory of their action; and our knowledge, though augmented of late years by the wonderful advance of organic chemistry and physiology, can scarcely yet be said to have passed the threshold of the inquiry. We must avow that this whole department of medical knowledge, so important in all its bearings, is the one where most remains to be done to raise it to the character of a science. The real amount of the deficiency can only be understood by a candid examination of the results of experience, and a fair comparison with other branches of physical knowledge.

To many, indeed, even of those conversant with practice, this will seem too disparaging a view of the science of medicine, and, in truth, the accustomed way in which the uses of medicine are taught, and the methodical forms under which they are classed and named according to their alleged effects, do favor the persuasion of a more advanced state of knowledge than that just described. It might be enough, perhaps, to refer those who doubt the reality of the view I have taken to what is unequivocally known of each one in particular. It will be found that ambiguities of language crowd around every part of the subject—that classification, while clearing away some difficulties, has created many more—than evidence, feeble in its origin, has often gained weight by mere transmission from one hand to another—and that this matter is peculiarly one where the prejudices and credulity of the world usurp upon the sense of the practitioner,—and warp his practical judgment.

If the truth be really as here stated, in regard to our knowledge of internal remedies, it is a feeble and useless policy to disguise what is thus deficient. The avowal may more readily be made;—first, because the difficulties to be overcome are greater than in any other science of observation or experiment;—and secondly, because, despite these difficulties, the scope and prospect of future attainment are ample and certain, and the connection with such other branches of physics, that the progress of each is fitted to throw light upon what is here doubtful or obscure. Already it may be affirmed that the recent methods of research in medicine have gained greatly in exactness, and the just appreciation of evidence, upon those of any previous period;—a natural effect of increasing exactness in all other branches of science; and, it must be added, of increasing and well-directed energy amongst those engaged in the profession. The deficiency just stated is greater, perhaps, than any other, and more difficult of redress; but time and various new means and appliances are in our hands, and it would be an injury done to the cause of science to doubt their effects.

A very special advantage we now possess consists in the application of numerical methods and averages to the history of disease; thereby, giving it the same course and certainty of result which belong to statistical inquiry on other subjects. We do not exceed the right expression of fact, in terming this method of average one of the most important principles of instruments of philosophic research. Little, if at all, recognized as such in former times, it has now become

a law in itself, and the index and interpreter of truth in every department of human knowledge. Under the guiding genius of the great Herschel and Struve it has been applied to the most profound questions in sidereal astronomy; while under a widely different use, it has been brought to the solution of some of the most curious problems of human life and social existence. The vast interval between is replete with examples of its successful application.

Averages may, in some sort, be termed the mathematics of medical science. It is obvious, indeed, that the value of inferences thus obtained, depends on the exact estimate of what are the *same facts*, what merely connected by resemblance or partial analogy. The principle in question is, indeed, singularly effectual in obviating the difficulties of evidence already noticed; and the success with which it has been employed these few years, by many most eminent observers, affords the only assurance of the results that may hereafter be expected from this source. Through medical statistics lies the most secure paths into the philosophy of medicine. This method of inquiry which so greatly distinguished Louis as a pathologist, may be noted as one of the eminent examples of this method, which is now pursued almost universally by the medical profession. Numerous results and generalizations have been accomplished by us, otherwise wholly unattainable in any other way; and, on the simple principle of averages, every year tends to enlarge and confirm these conclusions.

In looking further to the chance of overcoming these difficulties in the future, regard must be had to the principle now verified in so many cases, that in proportion to all complexity of phenomena, is augmented also the number of relations in which they be surveyed and made the subjects of experiment.†† The application of this principle to medical science is every day becoming more apparent. The fine expression of Laplace, "Tout se tient dans la claime immense des vérités," is well exemplified here. Every new path of physical knowledge opened, each simple fact discovered, has given guidance more or less direct towards the objects still unattained in physiology and the treatment of disease. The unexpectedness of some of the relations, thus determined and converted to use, is the best augury for further advances in this direction of pursuit.

A due estimate among medical men themselves of the nature of the proofs with which they have to deal is more especially needful now, when the older doctrines of physic and physiology, and in fact all allied branches, are all undergoing the revision required by modern science; and when new medicinal agents are every day produced upon trial, many of them dangerously active in their effects, many suggested by analogies which need to be verified by the most cautious experience. Hasty and imprudent belief may here become a cause of serious mischief;—the wider in its spread, as the minds most prone to this credulity are those most ready also to publish to the world their premature conclusions; and thus to mislead the many who found their own practice upon faith in others; or who seek after novelty, as if this were in itself an incontestable good.

And here I must advert to another circumstance which renders strict attention to the laws of evidence of matter of peculiar obligation at the present time. This is the tendency, so marked in modern physiology, to carry its researches into the most abstruse questions connected with vitality, the nervous power, and the relations of mental and material phenomena—inquiries justifiable in themselves, but needing to be fenced around by more than common caution as to testimony, and the conclusions thence derived. Yet here especially it is that such precautions have been much disregarded;—partly, it may be, from the real difficulty and obscurity of the subject—still more, perhaps, from the incompetency of many of those who have taken it into their hands. For these researches, no longer confined to a few as heretofore, have become the property and pursuit of many who wander merely in the confines of science, believing they are within its pale; and whose speculations on what they see are

††M. Comte, in his "Cours de Philosophie Positive," has defined this as a general law, through which compensation is made for the difficulty or impossibility of giving a mathematical form to certain branches of physics, such particularly as relate to the phenomena of organic bodies.

little checked by collateral knowledge, or by a due estimate of the laws and limits of scientific inquiry. The mystery of the subject is in itself a charm and seduction to the mind. They see and give attention for the first time; to those wonderful phenomena, which, though inherent in the constitution of man, and in the relation of his mental and corporeal nature, are not familiar to common observation. The feelings are thereby excited even more than the reason; and belief is hurried on and results accredited, with little care for the sufficiency of proof, or knowledge of the many facts which otherwise explain, or conflict, the conclusion. However earnest the desire for truth, imposture rarely fails to mix itself with inquiries so conducted; and increases the practical evil which always, more or less results from error. Every philosophical doctor is bound to watch over these events as they pass before him; never refusing inquiry, because what is put forward is new or strange; but requiring evidence in proportion to the unusual character of the facts; sifting closely that which is offered, and rejecting all conclusions not founded on this basis.

While speaking on the question of evidence as applied to these subjects, it is impossible not to advert to the fact—a very important one in the history of the human mind—of the great diversities of intellectual constitution as to this point. It is in truth a striking expression of the difference of the reasoning power, testified on the most ordinary occasions of life, and very remarkably where the subjects rise to the character of science. Locke has well said: "There are some men of one, some of two syllogisms, and no more; and others that can advance but one step further." The distinction here expressed applies closely to every question of evidence. One man concludes upon proof which to another has neither weight nor pertinency. One mind pursues a subject throughout all its relations; another follows but a single line toward the results. "Some men, in passing through the boundless ocean of disquisition, mistake fogs for land." There are others whom Lord Bacon calls "ill-discoverers, who think there is no land when they can see nothing but sea." Such, indeed, are these natural disparities, as in many cases to preclude any mutual understanding or communion of the reasoning power.

In commenting on these facts we can not rightly exclude the remark that a certain amount of speculation, duly guided, enters into the purest form of inductive science. Even could the mind be restrained from excursions beyond the strict bounds of evidence, such restraint would be a wrong done to that genius, which has often through these speculations opened a path to new and more certain knowledge. Instances of success, thus obtained, might be drawn from the history of the most eminent philosophers, and from the records of every part of physical research. It is not hypothesis, but conclusions founded on false or faulty evidence which are the bane of all philosophy.

I must further add here, that in questions of medical evidence there may be an excess of skepticism as well as for credulity. Sometimes this occurs in effect of a temperament of mind (not uncommon among thinking men) naturally disposed to see all things under doubt and distrust. There are other cases, where the same feeling, not originally present, grows upon the mind of physicians who have been too deeply immersed in the details of practice. The hurried passage from one patient to another precludes that close observation which alone can justify, except under special circumstances, the use of new remedies or active methods of treatment. From conscience as well as convenience, they come to confine themselves to what is safe, or absolutely necssary; and thus is engendered by degrees a distrust of all that lies beyond this limit.

Though such skepticism be less dangerous than a rash and hasty belief, it is manifestly hurtful in practice, and an unjust estimate of medicine as a science; both as it now exists, and as it is capable of being extended and improved. No one can reasonably doubt that we have means in our hands admitting of being turned to large account of good or ill. Equally unreasonable would it be to distrust the knowledge gained from a faithful experience as to the manner of using these

means,—and others which may hereafter become known to us—safely and beneficially for the relief of disease. The actual progress of medicine during the years in all that regards the principles of the science, as well as the details of practice, is the best testimony for the present and assurance for the future. As respects the two extremes noticed above, it is certain that there is a middle course, which men of sound sense will perceive; and to which they alone can steadily and consistently adhere, amidst the many difficulties besetting at once the judgment and the conduct of the physician.

I am rather led to these remarks on the nature of medical evidence and the causes, moral as well as physical, affecting it, by looking at the wonderful advances which have lately been made in all branches of science; not merely by the addition of new facts, but yet more by new methods and principles of research, by instruments of greater delicacy, and by increasing exactness of details in every point of inquiry. The effect of these changes has been (and it is a result the grandeur of which can be understood only by those who have pursued their progress) to bring the physical sciences into much closer relation with each other, pressing them on by converging paths towards that unity of principle which is the object and end of all true philosophy. I can not here do more than allude to the profound researches through which dynamical forces—the phenomena of chemical, electric and magnetic action—and those of light and heat—and several other advances have been submitted in so many cases to common laws; and the whole associated with the great doctrine of atomic elements, acting and combining in definite proportions throughout every part of the material world. These generalizations, great though they are, do not narrow the field of the future inquiry; but give fresh space, new objects, and higher incitements to those who may pursue such researches hereafter.

The dissimilarity of the proofs, and the greater difficulty of their certain attainment, must ever keep practical medicine in the rear of other physical sciences, notwithstanding its closer association with them through the laws of animal physiology and organic chemistry, so largely explored of late years. But its still wider scope of usefulness requires that this distance should be abridged as far as possible, and on no occasion be lost—by improved methods as well as by new facts—by more cautious observation and more exact evidence—of maintaining its place and connections among the other greater objects of human knowledge.

Mental Healing.

BY R. C. CAVE,
St. Louis, Mo.

Those who preach the gospel of mental healing tell us that sickness is to be cured by disbelieving it, and firmly believing in the universality of divine truth, goodness, or God. As to just what is the curative agent that brings healing to the sick man who thus denies sickness, they speak in vague and general terms, and leave us somewhat in doubt.

They can not mean merely to affirm that mind acts on body, and that our beliefs may, and to a considerable extent do, affect our physical health; for that is admitted by the medical men against whom they inveigh, as well as by themselves. I have known more than one physician who, finding the patient not seriously ill, and needing nothing more than mental treatment, administered bread pills.

And, surely, mental healers do not mean to affirm that physical disease can be cured by the mere act of believing. Physical disease is either a fact, or it is not a fact. On the assumption that it is not a fact, it can not be cured at all; for there is nothing to cure. On the assumption that it is a fact however brought about, it can not be cured by the mere act of disbelieving it. In the nature of things, facts can not be made other than they are by our beliefs about them. If a man eats poisonous mushrooms, believing them to be esculent, his belief can not alter the fact that they are poisonous, and save him from their poisonous effects. If a man's lungs are diseased, whether by mortal mind or something else, his belief

that they are sound does not make them so. Besides, if the relief of pain depends on the sufferer's belief that he has no pain, it can not possibly be effected; for such a belief gives the lie to his consciousness, and is a mental impossibility. The pain is there. He is conscious of it. He may persistently deny it; but he can no more believe that it does not exist than he can believe that he himself does not exist.

Mental healers then, as I understand them, do not mean that the cure is effected by the mere belief of the patient; but they mean that the patient's belief calls into exercise in his behalf the healing power of God. They cite the alleged miraculous cures wrought by Jesus in support of their claims, and lead us to infer that their cures are effected in the same way—that as divine power was put forth to cure the sick who, turning from material aids, came to him in faith; so divine power will be exerted now to heal those who, refusing the help of doctors and drugs, lift their minds and hearts to the Universal Spirit for help. So, we are told, Mrs. Eddy read the story of the man who was healed of the palsy, and "the power which gave him strength, she felt. The life divine which healed the sick of the palsy restored her."

Thus the theory of mental healing seems to be in line with the old conception of divine providence, according to which, God, as Luther said: "powerfully and miraculously preserves and defends" those who trust in him. The mental healer, in substance, says to the sick man: Deny your sickness; believe in the all-pervasiveness of the good; thus bring yourself into accord with truth, love, goodness, or God, and you will be healed by divine power, as the sick were healed by Jesus. In some wonderful way, your organs, however diseased they may be, will be restored to perfect health, so that they will perfectly perform their proper functions. A miracle will be wrought on you, like that said to have been wrought on blind Bartimeus.

Of course, men of the medical profession deny this theory. They do not believe in miraculous cures. They do not deny that God heals the sick; but they maintain that, whatever we may call the power that heals, it effects the healing through the action of natural forces—cures by the use of natural means. In many cases (such as are said to be cured my mental healers), the natural forces of the body, making for health, are able to throw off its ailments. In other cases, these forces are so weakened that they can not throw off disease without the aid of medicine which, by its action, works with them to produce the desired result. In any case, it is nature effecting the cure.

But God is in nature. The forces of nature, animate and inanimate, are but different forms of the one divine energy. The properties of medicine, as truly as the powers of mind, are expressions of this energy. Hence, what is effected by the one, as well as what is effected by the other, is effected by God; and, even if mental healing were true, it would be no more divine than healing by the use of medicine.

General Remarks of the Pelvic Floor.

BY BYRON ROBINSON, B. S., M. D.,
Chicago, Ill.

In general there are numerous conflicting views regarding the structures and utility of the pelvic floor. Even the name is not settled with either anatomists or gynecologists. Also it is of remarkable interest to observe extensive and varying differences between the views of the anatomist and gynecologist as to structure and function of the pelvic floor. The word perineum comprehended the structure at the exit of the pelvis for many years. It may be well to mark the limitations of structures by simple definitions, so that definite onamatology may lead to definite conception of structures. There are three terms employed by writers, viz.: 1, pelvic floor; 2, pelvic diaphragm; 3, perineum—which should be defined.

1. The *pelvic floor* is composed of all the anatomic structures in the pelvic outlet which support the viscera and resists the intra-abdominal pressure. The pelvic floor comprises the structures between skin externally (distally), and peritoneum

internally (proximally), and which combine to close the pelvic outlet. The elements of the pelvic floor are: (*a*) peritoneum, (*b*) fascia, (*c*) muscle, (*d*) skin, and (*e*) viscera. The following table presents, in a bird's-eye view, the elementary anatomic structures of the pelvic floor:

ANATOMY OF THE PELVIC FLOOR.

A) Peritoneum.

(B) Muscles.
- I, Anal Group.
  - 1, Levator ani.
  - 2, Coccygeus.
  - 3, Pyriformis.
  - 4, Sphincter ani externus.
- II, Pudendal Group.
  - 5, Sphincter vaginæ.
  - 6, Erector clitoridis.
  - 7, Transversus perinei profunda.
  - 8, Transversus perinei superficialis.

(C) Fascia.
1. Levator ani fascia, proximal and distal.
2. Obturator fascia, proximal and distal.
3. Coccygeus fascia, proximal and distal.
4. Pyriformis fascia, proximal and distal.
5. Sacral fascia.
6. White line (arcus tendineus.
7. Perineal layer.
   - (a) superficial fascia, superficial layer.
   - (b) superficial fascia, deep layer.
8. Trigonum urogenitale—triangular ligament.

(D) Skin.

(E) Viscera.
6. Bladder, 23.
7. Urethra, 24.
8. Vagina, 25.
9. Uterus (key), 26.
10. Rectum, 27.

2. The *pelvic diaphragm*, diaphragma pelvis, I shall limit to three structures, viz.: (*a*) the levator ani fascia, proximal, (*b*) levator ani muscle, (*c*) the levator ani fascia distal.

In other words, the pelvic diaphragm consists of the levator ani muscle with its proximal and distal fascia. Some writers describe the pelvic diaphragm as the anatomic pelvic floor, while the sacral and pubic segments is the physiologic pelvic floor.

3. The *perineum* is practically the pelvic floor. At present, by some writers, the term perineum is limited to the skin space between the distal ends of rectum and vagina. The perineal body is the "fusion point" of perineal structures. The term perineorraphy, at present classically fixed in medical literature, indicates that it attempts to repair damaged structures in the pelvic floor resulting from parturition, or other causes—respiration (splanchnoptosia). Recent labors have attempted to classify the pelvic floor structures and functions, and to utilize them in repair.

The names of Berry Hart, Schatz, Tait, Dickinson, Sellheim, Hanks, Studdiford, Burtenshaw, Webster, Harris, Newman Dorland Marcy, Thompson Holl and others have added to the progress of the pelvic floor repair.

The structures involved in the repair of a defective perineum are muscles and fascia. The operative procedure consists of denudation with coaptation or flap-splitting methods. Notwithstanding the successful claims for the varied surgical methods of coloperineorraphy, the anatomical basis is neither generally nor perfectly understood. It is probable, however, that the essential success lies in the reunion of the separated levator ani muscle by means of its fascia proximal (superior), and distal (inferior), with some other fasciæ, and also that this success has been chiefly due to deep suturing. The object of this essay is to demonstrate that the chief factor in successful colpoperineorraphy is the restoration by the aid of deep sutures of the fasciæ, especially the levator ani fascia, proximal and distal.

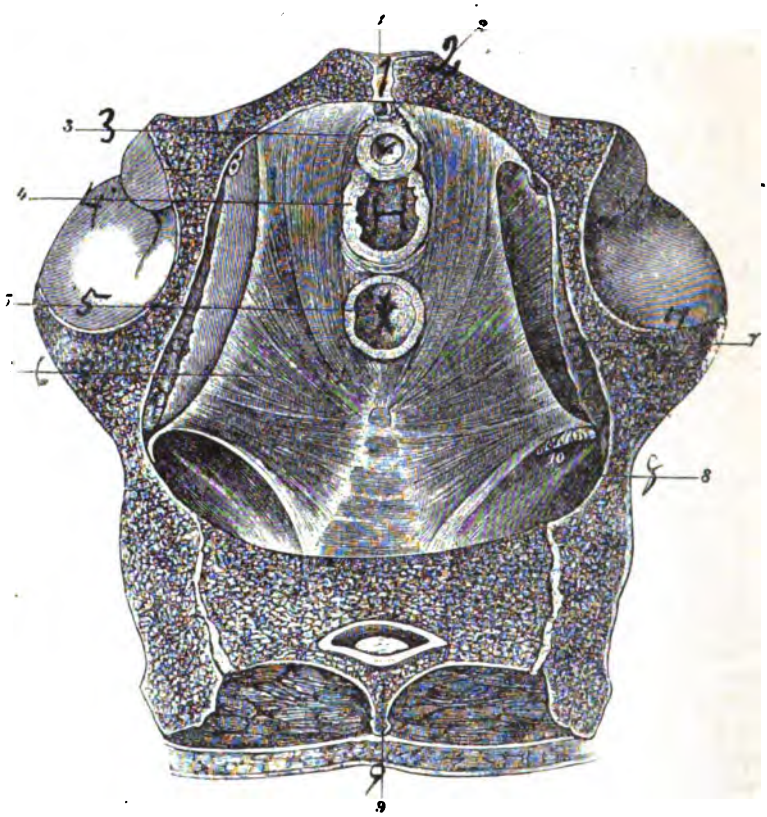
The muscles of the pelvic floor may be divided into two classes: *a*, the deep layer—the levator ani coccygeus and pyriformis; *b*, the superficial layer—the transversus perinei, bulbo-cavernosus, erector clitoridis and sphincter ani externus. A peculiar characteristic of the muscles of the pelvic floor, and one which demands respect in colpoperineorraphy, is the extensive fascial attachment, one or both ends of the muscles. The levator ani, the bulbi-cavernosus and the transversus perinei have a fascial attachment. We will consider in detail the muscles and fascia involved in colpoperineorraphy. The basis of this labor is a careful anatomic investigation with considerable clinical and surgical experience.

The diaphragma pelvis, or anatomic pelvic floor, is a fascio-muscular floor, and lies in bony space of the pelvic exit. The pelvic exit is closed by the diaphragma pelvis and the triangular ligament. The white line—condensed fascia—in man's pelvic fascia is a special development due to erect attitude. In general, the function of the pelvic floor is to control the constriction of the anus and vagina, aid

in parturition, to offer resistance and support of the pelvic and abdominal viscera. The major factors in function and structure of the pelvic floor are the levator ani muscle, with its levator ani fascia, proximal and distal. The levator ani muscle, with its levator ani fascia, proximal and distal; is materially assisted to strengthen the pelvic floor by the condensation of the transverse perineal fascia, or what is termed the ischio-perineal ligament, because of its attachment to the tuberosity of the ischium and perineal body. The pelvic floor is not a rigid transverse partition, it is an elastic and movable structure. The main object of the pelvic floor is to maintain the weight of the abdominal viscera, to accommodate parturition and resist intra-abdominal pressure. Dissection is superior to all other methods in gaining a knowledge of the nature of the pelvic floor, character and complex arrangements of its structure.

THE ELEMENTARY STRUCTURES OF THE PELVIC FLOOR.

In the following pages remarks may be offered as to the part played in the pelvic floor by its elementary anatomic structures: (*a*) peritoneum, (*b*) muscle, (*c*) fascia, (*d*) skin, (*e*) viscera—anatomically, physiologically and pathologically (*i. e.*, in repair).



MUSCLES OF THE PELVIC FLOOR.

FIG. 4. The musculature of the pelvic floor viewed from the proximal side after removal of the levator ani fascia proximal. 1, symphysis pubis; 2, perivesical tissue, ligamentum, vesicum ventrum; 3, neck of bladder; 4, vagina H-shaped; 5, rectum; 6, musculusi obturator internus; 7, arcus tendineus; 8, musculus pyriformis. This illustration presents the muscular bundles, loops surrounding the vagina and rectum. It suggests the direction of the levator ani contraction. (Savage.)

(A). THE PERITONEUM.

The *peritoneum* of the pelvis plays its chief role by maintaining with considerable vigor the pelvic organs in definite relations, conducting vessels, nerves and

structures in ordered plans and preventing organ entanglement. The peritoneum aids to a distinct degree in maintaining the strength of the pelvic floor or pelvic diaphragm. Its strong, smooth, shiny surface enables the viscera to glide on each other with minimum trauma. The peritoneum is an important and powerful factor in the utility of the pelvic floor.

(B). THE MUSCLES OF THE PELVIC FLOOR.

The function of the perineum or pelvic floor is exercised through musculature—*i. e.*, contraction and relaxation, constriction and control. The major functions of the pelvic floor are: (*a*) support of the pelvic and abdominal viscera—*i. e.*, resistance to intra-abdominal pressure, (*b*) control of the anal apparatus, (*c*) control of the vaginal apparatus, (*d*) aid in parturition. The above noted four complicated functions of the pelvic floor are dependent on intact muscles. We will divide the muscles in the pelvic floor (perineum) in: 1, the anal group, which are intimately related to the anus; 2, the pudendal group which are intimately related to the vagina. The following table presents the two groups of muscles of the pelvic floor:

Muscles of the Pelvic Floor.	I, Anal group.	1, levator ani. 2, Coccygeus. 3, Pyriformis. 4, Sphincter ani externus.
	II, Pudendal group.	5, Sphincter vaginæ. 6, Erector clitoridis. 7, Transversus perinei superficialis. 8, Transversus perinei profunda.

We will present a brief, practical description of the anal and pudendal groups of muscles:

Muscles of the pelvic floor combined form a muscular diaphragm which aids to strengthen the pelvic floor. However, since the levator ani, the chief muscle, is of marked thinness, of limited quantity, the muscular support must be limited. I shall adopt the simple practical division of the pelvic floor muscles as: 1, the anal group; 2, the pudendal group.

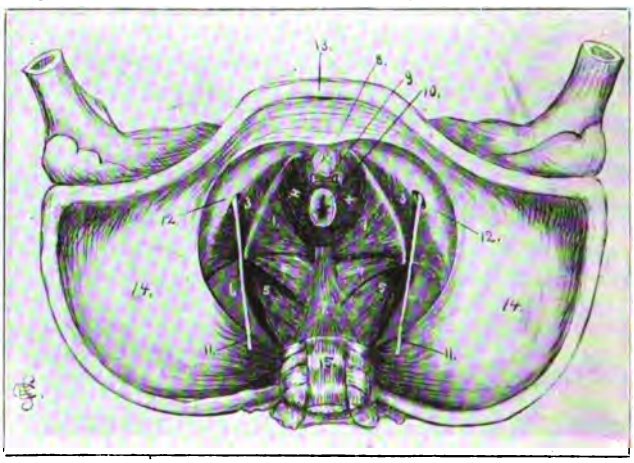
I. ANAL GROUP.

The anal group of muscles are intimately related to the anal apparatus.

1. *Levator ani muscle.*—The levator ani muscle is, perhaps the most difficult to understand as regards its form, insertion and function. The origin of the muscle is sufficiently plain, and is considered established by anatomists. Few agree as to exact insertion, even at this late day, and opinions vary as to the exact function, form and insertion of this muscle. My personal investigations demonstrate that there is a foundation for these varied opinions: (*a*) the *insertion* and *origin* of the levator ani vary as to the exact extent of distinct muscular loops which embrace the rectum and vagina, as to the tendinous raphe (between muscle loops and distal ends of the coccyx), also regarding the precise relation of the vaginal wall, whether muscular or connective tissue, and also as regards the exact relation to the muscle of the distal end of the rectal wall. Moreover, its partial fascial origin and insertion is sure to endow the extremities with varying appearances as to the length of the fascial (or tenderness) conditions; in other words, the distance of the red muscular fibers from the extreme origin and insertion of the levator ani vary. Perhaps this variation and insertion may be explained by considering the levator ani as a rudimentary muscle, and to be disappearing with the tail. Its double fascial accompaniments complicate its origin and insertion, as well as the interpretation of its function; (*b*), the various opinions as to the *form* of the levator ani are explained by differences as regards sex (idiosyncrasies of individuals, disturbances from gestation and parturition, variation of the shape of the pelvis and fascial insertions and attachments; (*c*), the different views as to *function* of the levator ani lie in confusing its function with the levator ani fascia proximal and distal, in exaggerating its dimension and attributing to it function and utility belonging to other genital supports. It is especially erroneously inferred that a muscle will act as a continuous tensionized support for any viscus. The knowledge of the levator ani muscle is fragmentary and difficult of access. Its dissection is far from easy, and its adjacent relations are complicated. The muscle does not resemble a funnel, with the rectum or vagina at the bottom or apex, but is more similar to a sling, a flat loop or a horseshoe, which does not draw the rectum or vagina directly proximalward, but

draws the two canals ventralward and proximalward toward the pubic arch.

The muscular loop of the levator ani muscle resembles a horse's collar encircling the rectum or the vagina. In the female it vigorously controls two canals—rectum and vagina—yet its control of the vagina depends on that of the rectum. The rectum being forced ventralward against the middle of the dorsal vaginal wall, produces the H-shape to the vagina. The excess of vaginal wall is compelled to fold at the sides producing the upright columns of the H. It is very thin, diminutive in thickness. In an excellent specimen which I dissected from a woman exceeding usual corporeal dimensions, the origin arises from the dorsal surface of the pubis. It begins about half an inch from the symphysis, and one and one-half to two inches distal to the pubic crest. This line of origin is about two fingers wide, or one and one-half inches, and does not meet its fellow of the opposite side, one-half to one inch existing between them on the dorsal surface of the pubis, which is occupied by the obturator fascia. The bundle of muscles originating on the dorsal surface of the pubis passes distalward and dorsalward to embrace the vagina and rectum. This is the pubic sling, or horseshoe loop, which is quite thick and strong in some cases, and very thin and membranous in others. The



MUSCLES OF THE PELVIC FLOOR VIEWED FROM THE PROXIMAL SURFACE WITH THE LEVATOR ANI FASCIA SUPERIOR REMOVED.

FIG. 5. This cut is drawn from a female pelvis dissected by myself and intended to show the muscular floor of the pelvis from which fascia is dissected: 1, 1, the levator ani muscle; 2, 2, the white line or origin of the levator ani; 3, 3, the obturator internus muscle; 4, 4, the coccygeus muscle; 5, 5, the pyriformis muscle; 6, 6, the inner wall of the pelvis; 7, 7, sacrum; H, H, the horse-shoe loop of the levator ani muscle, drawn darker; 8, the Y-shaped urethra; 9, the vagina, cut close to the pelvic floor, whose wall does not flare like the radial wall, 10; 11, 11, the obturator nerves; 12, 12, inner wall of pelvis; 13, pubic crest; 14, 14, iliac fossa; 15, last (5th) lumbar vertebra. (Dr. Schoeler was the artist).

levator ani muscle was so thin as to be really membranous, and the muscular band between the vagina and rectum is but a few lines in thickness. It is really a pelvic diaphragm.

The muscle should be considered as to its origin, course and insertion.

Origin.—The levator ani muscle arises from bone, from the dorsal surface of the pubis and ischial spine, or from fascia, arcus tendineus and vesicopubic ligament. The bony origin is the dorsal surface of the pubic bone and ischial spine. The larger portion of the levator ani of bony rounded margin of the loop, which is applied against the sides of the vagina and rectum, is often the thickest part of the muscle. The muscular bundles of the horseshoe loop join those of the opposite side of the levator ani dorsal to the vagina and rectum without an intervening perineal tendon or raphe. In some dissections it is absolutely plain that no tendinous raphe exists, while in others it can not be told.

The *smaller* portion of the levator ani of bony origin is from the *ischial spine* immediately ventral to the origin of the

coccygeus muscle. Quite a distinct strip one-fourth to one-half inch wide arises from the ischial spine, and can be plainly followed by the eye to the horseshoe loop.

The *ligamentous* origin is from the ventral ligament of the bladder (ligamentum pubo-vesicale), and from the arcus tendineus (white line). The fibers of the levator ani which arise from the ligamentum pubo-vesicale are of little practical importance. The white line extends in a slightly curved direction from the dorsal lateral surface of the pubis, over the obturator foramen to the spine of the ischium. The central end lies two and three-fourths inches below the ileo-pectineal line, with a length of about four inches. The white line (arcus tendineus) is a part or an extension of the ventral true ligament of the bladder, a thickening of the levator ani fascia proximal. In the white line, the muscular fibers arise as fine tendinous bands, crescentic in form, and may show their reddish muscular nature at the white line or a short distance from it. The most distal portion of the arcus tendineus is about two inches distal to the ileo-pectineal line. The white line, arcus tendineus, the crescentic, curved line of ligamentous origin of the levator ani, is profoundly connected with the pelvic fascia, and the muscular fibers of the levator ani begin as tendineous fibers which variate from the white line. The ligamentous origin of the levator ani muscle is the blended coalesced and powerful fibrous, fascial planes of the levator ani, proximal and distal. The muscle may shade into a flat tendinous layer before it reaches the white line. The proximal tendon of the levator ani muscle varies much as to its relations with the white line. It may arise distal to it as well as from it. The white line may project into the pelvis as a tendinous fold, and be capable of being separated from the origin of the muscle.

Course.—The course of the fibers of the horseshoe loop of the levator ani muscle is dorsalward and distalward in two fleshy bundles, the smaller coursing along the lateral and dorsal surface of the vagina, and the larger coursing along the dorsal and lateral wall of the rectum. The loop which passes along the sides of the vagina seems to be attached to the vaginal walls by connective tissue only, while the loops of muscular fibers which embrace the rectum interweave and blend with the muscular bundles of the rectal wall, forming a strong connection. The part interwoven in the rectal wall acts as an elevator. It would appear that in some cases the loop of the levator ani interweave

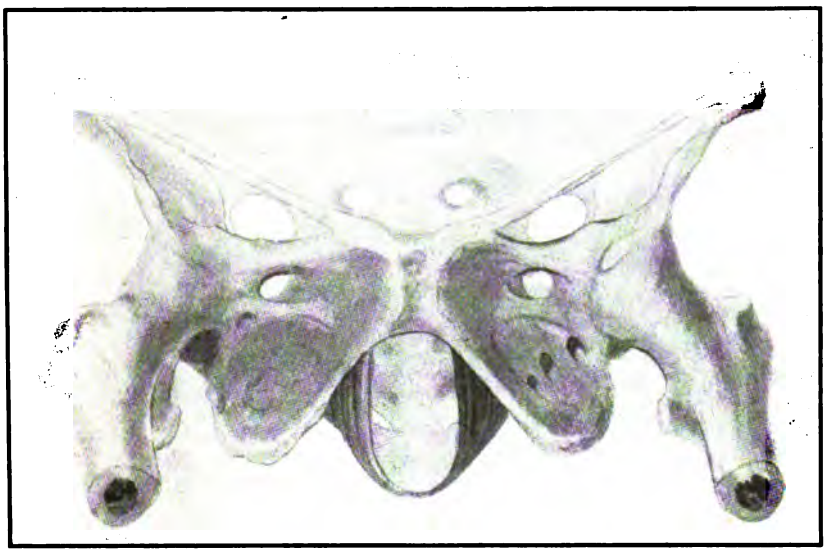


FIG. 6. Levator ani, as seen with the pelvis in a semi-recumbent position (modified by Dorland from Dickinson).

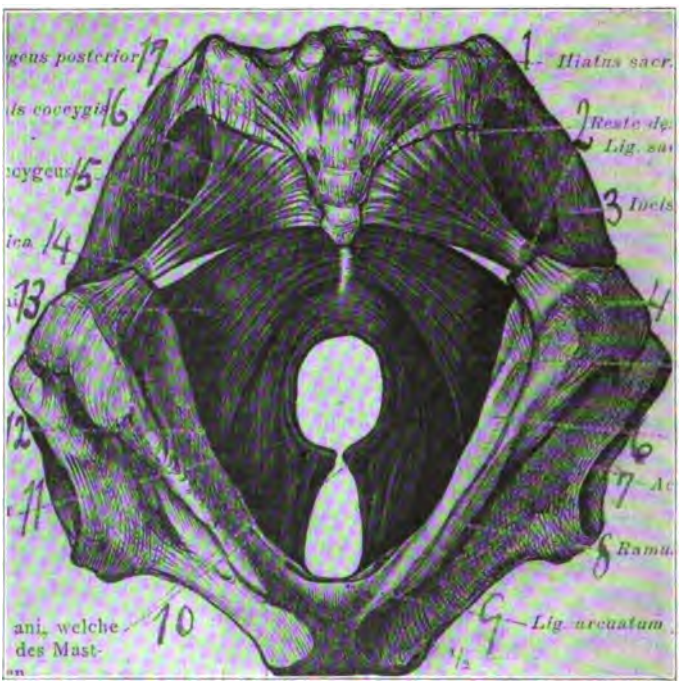
with the muscular fibers in the wall of the vagina. The part of the levator ani which passes between the vagina and rectum is a small, thin band, one-sixth to one-eighth of an inch in width, which arises from the external part of the pubic origin, and passes over the large belly of the muscle to gain the recto-vaginal situation. Its relations to the wall of the vagina are very close, if not interwoven with its fibers.

The part of the muscle of fascial origin which arises from the white line, passes dorsalward and distalward, becoming part of the levator loop, and partly inserted in the tendinous perineal raphe and the last bone of the coccyx. Many of these fibers pass distalward in a curved direction, and when near the median raphe they turn acutely dorsalward to become inserted into the coccyx. A few of the muscular fibers arising from the white line, as well as from the horseshoe-shaped loop, together with some from the ischial spine, embrace the rectum. The part of the levator ani arising from the ischial spine becomes inserted chiefly in the coccyx. Yet one may observe one-fourth of an inch in width pass around the rectum with no intervening tendinous raphe.

The part of the levator ani muscle of special interest to the gynecologist is the two-finger-breath horseshoe-shaped sling which arises from the dorsal surface of the pubis and passes dorsalward and distalward to embrace both rectum and vagina. It is the belly of this loop which gives the rectum its ventralward curve immediately proximal to the anal end which is turned dorsalward. It is the rectal sphincter portion of the muscle. It is this part of the muscle which becomes hypertrophied in vaginismus. It is the portion of the muscle torn, elongated and separated in lacerated perineum. It is the portion of the muscle which may retard labor, create violent vaginal spasm, and may prevent coition or digital examination, and, in rare cases, prevents the penis from escaping until relaxed by an anes-

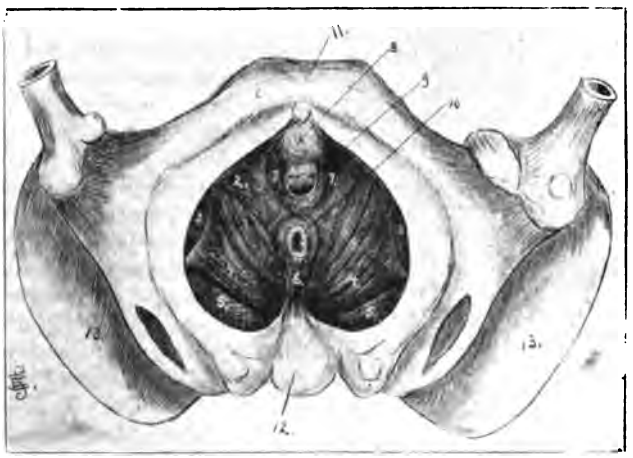


THE MUSCLES OF THE PELVIC EXIT.

FIG. 7. 16, apex ossis coccygis; 15, musculus coccygeus; 14, spina ischiadica; 13, musculus levator ani (pars iliaca); 12, musculus levator ani (pars pubica); 11, remnant musculus sphincter ani externus; 10, bundle of the levator ani muscle which is located on the ventral surface of the rectum. The pubic and iliac segments of the levator ani are plainly visible (illustration from Carl Toldt).

thetic. In most cases the levator ani dorsal to the rectum may be divided into three quite distinct parts, viz., (*a*) the part which is connected to the last bone and fascia of the coccyx. The fibers accompanying this portion of the muscle originate chiefly from the dorsal end of the white line, or at the ischial spine; (*b*) a portion of the muscle forms a median tendinous raphe for about one-third of an inch immediately ventral to the coccyx; (*c*) the portion of the muscle immediately dorsal to the anus, about three-fourths of an inch in width, has no intervening tendinous raphe (not always distinct), and consists of the belly of the loops which originate and insert on the dorsal pubic surface. In other words, the muscular fibers of each side anastomose, forming the horseshoe-shaped loop, with no intervening tendinous raphe. Some of the loops intertwine with those of the sphincter ani, which pass dorsalward to the tip of the coccyx, also some of the muscular fibers of the sphincter ani externus are continuous with the loops of the levator ani. The fibers of the levator ani originating from the white line pass dorsalward and distalward, however, on arriving at the median raphe; many of the fibers turn sharply dorsalward to be inserted into coccyx, and rapidly become tendinous. The levator ani fascia proximal is not very intimately attached to the proximal muscle surface, and may be compared to the fascia transversalis. The levator ani fascia distal is quite adherent to the muscle.

From this description of the levator ani from actual dissection, it will be observed that the insertion of the levator ani is: (*a*) at the opposite side of the pelvis from the identical location of its fellow origin; (*b*) to a limited degree in the median tendinous raphe; (*c*) some fibers may be inserted in the coccyx, rectum, vagina, perineal body, external rectal sphincter.



LEVATOR ANI MUSCLE VIEWED FROM THE DISTAL SURFACE.

FIG. 8. This is a cut drawn from a female pelvis dissected by myself. It illustrates the distal surface of the muscular pelvic floor. On the left side the levator ani fascia distal is not dissected off, while it is on the right side, showing the distal surface of the levator ani muscle. 1, 1, shows the levator ani muscle with its parallel bundles; 2, the levator and fascia distal; 3, 3, the obturator internus muscle; 4, 4, the coccygeus muscle; 5, 5, the gluteus maximus; 6, anococcygeal structure; 7, 7, the horse-shoe loop of the levator ani, showing some muscular bundles coursing between rectum and vagina. It is not so large in area on the distal surface as it is on the proximal surface of the pelvic floor. 8, urethra; 9, vagina; 10, anus flaring; 11, pubic arch; 12, sacrum; 13, flaring ilium. (Dr. Scholer was the artist.)

Deductions in regard to the levator ani muscle may be numerous. Certain practical considerations may be drawn from a careful study by dissection and in gynecologic practice. As it was originally a muscle of the tail, it is becoming vestigial in man, shown by its fascial connections. From the origin, course and insertion of the levator ani muscle, it must be viewed as the all-important muscle of the pelvic floor.

(To be Continued.)

[Written for the MEDICAL BRIEF.]

Treatment of Erysipelas of Trunk and Extremities by the Continuous Warm-Water Bath.

BY DR. A. ROSE,
New York.

PRACTICAL NOTES, NO. IV.

There exist numerous remedies against erysipelas, but the most rational, the most reliable against erysipelas of trunk and extremities is very little known, at least I did not see it mentioned in literature ever since I spoke of it, about fifteen years ago, when I presented two cases before a medical society, which were published in the year 1890.

In the year 1888 I saw, in consultation with Dr. Treskatis, a woman who was suffering from erysipelas of hand and forearm. The inflammation had existed several days. One physician had ordered ice application, the second, Dr. Treskatis, who had called me in consultation, had prescribed an antiseptic ointment. I found the patient with high fever, and complaining of pain. The left hand, the left forearm, and part of the lower third of the upper arm erysipelatous. I had at once the arm suspended in a warm bath—an oval-shaped, large wash-kettle serving as bath-tub—a hammock was improvised from muslin, reaching from one handle of the wash-kettle to the other, in which hammock the arm was placed so that hand and elbow were on a level. When I saw the patient again on the next day, fever and pain had completely subsided; the appetite, which had been wanting, had returned; corresponding with this change for the better the general condition was perfectly satisfactory, and this was the end of the erysipelas.

The second case was that of a boy of three years. The erysipelas had proceeded from an apparently insignificant abrasion at the knee. On August 5, 1889, the mother noticed a circumscribed redness in the region of the injury; on August 7th she consulted a druggist in the neighborhood, who prescribed for the child for three days. On August 10th, at night, the little patient was brought to my office. There was erysipelatous inflammation extending from the toes all the way up to the upper third of the thigh. The temperature was 105° F.; the child, with a phenomenally strong voice, was screaming constantly. At that time there was so much praise given to a new method introduced by two eminent surgeons, Riedel and Kraske, that everybody, having a case of erysipelas of the extremities, would give it a trial. In this case of the boy of three years I myself gave it a trial. Under chloroform narcosis I washed the affected limb first with soap and water, then with ether, and finally with a five per cent solution of carbolic acid. After this I made the scarifications in the sound skin all around the border of the erysipelas, and covered the whole leg with gauze, saturated with two per cent carbol solution, and ordered that this gauze should be kept moist continually.

When I saw the patient later in the night, about three hours after I had applied the Riedel-Kraske dressing, he had been resting quietly, for the first time in several days. I did not measure the temperature for fear of disturbing the sleep. Next morning I found a temperature of 103.5° F. The erysipelas had over-stepped the scarification. The powerful voice of the boy was heard incessantly, alarming the whole house. I removed at once all dressing, placed the patient in a bath-tub filled with warm water, and watched the effect. After having been in the water only a few minutes he commenced to feel comfortable. In the evening the temperature was normal; the child slept all night in the bath. No rise of temperature on the following day and evening. The general condition, likewise, being all that could be desired, I had the patient taken out of the water, neither fever nor pain returned, and this was the end of the erysipelas symptoms in this case.

The warm-water bath is of wonderful effect in case of pain. I can not understand why there are so many remedies and methods, for instance, against combustion, while we have in the continuous warm bath the really ideal means of treatment of combustions of all degrees and extents (except the head). It keeps the wounds aseptic, and relieves pain better than anything. Napoleon, on St.

Helena, appreciated this calming effect; he remained sometimes for days in the warm-water bath to find relief from his pains, caused by cancer of the stomach and liver. In his testament he wrote: "If my body is to remain imprisoned on St. Helena after my death, I desire to be buried at the foot of the spring to which I owe so much relief." The fountain of which Napoleon speaks was situated quite a distance from Longwood, and Sir Hudson Lowe, on account of the trouble it gave to carry the water for the bath, wanted to deprive Napoleon of the latter, saying: "Why does he want to stew himself in hot water?"

The explanation of the action of the warm bath in erysipelas is so simple that the everyday man can understand it, but this seems to be the reason that the great men in the profession will not pay attention to it.

It is an established fact which nobody can take out of the world, that the continuous warm bath exerts an irritation on the skin, in consequence of which the vaso-motor nerves are influenced, causing dilatation of the blood vessels. Dilatation of blood vessels means acceleration of circulation of the blood. Accelerated circulation in the parts submersed in warm water causes the products of inflammation and infection in these parts to be taken up, carried away and eliminated through the general circulation. This is, in a few words, the explanation how the continuous bath acts in erysipelas.

In my book, "Carbonic Acid in Medicine," I have given the full description of the physiological action of the continuous bath, and beg to refer to these explanations. Here I will confine myself to a few words: There is a difference between hot and warm baths which we have to consider seriously. The hot bath (about 120° F.), can not be borne for more than a few minutes; it is of great service under certain conditions and circumstances, but it is not to be thought of in the treatment of erysipelas. The warm bath of a temperature of about 98° to 100° F., is well tolerated for any length of time; for days, weeks, months, and cases are on record in which, in the treatment of skin disease, patients had been kept in the warm water bath continuously for over a year.

Since I reported the two cases here described, I have always treated erysipelas of the extremities in the same manner, and invariably with the same gratifying result. I would give quite a voluminous report, but the two first cases are so striking, giving such unmistakable facts, that I think they may suffice to induce our colleagues to try the continuous warm-water bath in erysipelas, and to report the results for the benefit of the profession at large.

[Written for the MEDICAL BRIEF.]

The Dynamics of After-Life

BY AXEL EMIL GIBSON, M. D.,
Los Angeles, Cal.

"There is more between Heaven and Earth, my dear Horatio, than all our philosophy has ever dreamt about."—HAMLET.

In Touch With Impalpables.—We had met—my deceased friend and myself—under circumstances which the thoughtless would attribute to the empire of chance, but which the philosopher appreciates as integral and law-governed parts in the eternal fitness of things. Though born and raised under antipodal signs of nature and culture, we had yet imbibed the same fundamental aspects of life and destiny, impelled by the same inappeasable passion for knowledge, to pursue, rationally and scientifically, the dynamics of after-life.

She died, as we all do, from failure to fully understand and fully live up to the minutiæ of the plan embodied and ensouled in the free, rhythmic throb of the world-life. She died in my arms, sane and hopeful, philanthropically not less than intuitively convinced that death should cause no arrest of her evolution, but rather be instrumental in opening up new fields of research and realization.

But before she died, she had whispered between the hectic convulsions: "Gerald, if I am to change the theater of existence for some more needed experience, I shall endeavor to communicate with you, and lay before you scene after scene of the panorama of after-life."

These words alone consoled me for the loss of her cherished earthly association. For in the light of that promise her departure became merely nominal. As souls and thinkers we ignored death, fixing our attention with unquestioning certainty on the conscious continuation of individual identity beyond the threshold.

About a week after her death, while sitting in my library and looking through some of her posthumous notes, with a view of publishing them, I suddenly felt a cold draft of air with great force strike my face, while the room was rapidly filling with the odor of putrid flesh, peculiar to the presence of a corpse. Looking up from my work, I beheld in front of me a dark, shrouded form, swaying from side to side, as if exposed to a heavy gale, a form which I instantaneously recognized as belonging to my deceased friend. A drab-colored tunic, covering head and body, parted at the flurry of a gesture, and uncovered a face emaciated and careworn, and over-drawn with deep-laid lines. From two deep, dark sockets I saw the piercing light of her eyes shine with intense and nervous energy.

She articulated syllables with great rapidity, coloring her sentences with German, French and English idioms—languages with which she had been familiar while on earth. But did she really speak?

I saw the lips moving, the hands gesticulate, the spare form swinging to and fro, and yet the excitation of my sense of hearing, resulting in an intelligible response in my mind to this epiglottic stream of ideas, did certainly not come over the path of the eighth cranial nerve. The waves of vibratory motion gave rise to verbal utterance without being accompanied by sound. Did a receiver in some of the departments of the vast *terra incognita* known as "psychic centers" register waves of motion along "wireless" paths, and reflect them over the *roads of Corti* into the mediating and interpreting agency of the mind, and there start reactions in terms of audible sensations? Or was the entire process a direct registration of the soul in terms of sympathy and feeling, introducing the descriptive imagery of the mute speaker into my consciousness without involving the cumbersome agency of cerebral machinery.

"Do not grieve," she articulated with great vehemence, "grief is pain—a missile of agony darting through the soul of those to whom it is directed. Please do not grieve."

Strange to say I was neither shocked nor surprised. I listened to her statements with the same interest and philosophical absorption as in former days, when we used to discuss problems of life and destiny. Interrogating her about the effect of grief as a purely subjective force, I spoke aloud at first, but, startled at the sound of my voice, and with a sudden realization of the inappropriateness as well as needlessness of vocal utterance, I proceeded to formulate the thoughts in my mind, without translating them into words.

She referred to grief as a species of thoughts, and as such possessing qualities characteristic to the latter. Like thought, it is a carrier of emotion. And, furthermore, as grief stands for the realization of all that we failed in doing or undoing for the departed while they were yet with us, a realization intensified and magnified by the consciousness of our utter helplessness in regaining lost opportunities of demonstrating to them our faith and affection, it follows that the energy with which grief charges its messages carries a tremendous potency, embodying in its impulse all that is dynamic and forceful in our personal nature. If to this we add the fact of common experience that thought has the power of changing the nature of gross, molecular substance, as witnessed in its action on the anatomical and physiological groupings of our body—thereby giving expression to character—it can be readily realized what effect grief must have on the soul itself when the latter is no longer shrouded and protected by a gross physical covering.

"The pain which your grief inflicts on my soul is indeed real, and strikes me as resembling the piercing, lancinating sensations experienced by the victims of locomotor ataxia at a certain crisis in their progressive break-down. I assure you again that these sensations of grief have to me the entire reality of objective touch, streaks of lightning, leaping through and through my quivering substance, crossing and recrossing my sphere

of identity until my entire nature feels honeycombed by invisible, trackless, uncontrollable arrows of flame. Ah, I beg you, do not grieve! If mothers realized the pain their grief inflicts upon the very objects of their love, they would wipe away their tears, and replace them with a smiling and hopeful countenance. For sunny, cheerful, hopeful thoughts are like stimulating draughts for a thirsty and tired-out body. Oh, ye mourners and grief-stricken lovers of the dead, give joy, not grief, strength, not—"

The words grew fainter and fainter, and finally became inarticulate and lost in a stream of unintelligible mutterings. Simultaneously, changes of dissolution appeared in her features, which began to lose their lineaments and gradually fade out of objective vision. A moment later the phantom was dissolved, and the four walls of the room, which for the time being I had lost sight of, again enclosed me as concrete and impenetrable as ever.

I describe these and the following scenes as minutely and *ad verbatim* as my memory enables me. If an illusion, then I am not less illusioned than the reader. The whole matter stands before me at once, incredible, yet real; a fairy tale, and yet concrete history.

It is needless to state that I henceforth stopped grieving, and gave my whole thought-life a higher vital tone, charging every feeling with perennial buoyancy and hopefulness.

About a month after this experience, in the early twilight of a Swedish winter day, in which country at the time I was sojourning, while sitting in my library, wrapt in memories of the past, and with my eyes resting on a miniature portrait of my dead friend, I suddenly felt the strange, chilling, uncanny touch of a damp, malodorous garment creeping over me. I at once became conscious of the presence of my dead friend, and recognized with no surprise whatever, the appearance immediately in front of me, of her old dear face, wrapt in the same loose, dark-colored garment as when I last saw her. She seemed to move in a sphere of intense excitement; waves of stirring emotions dashed over me like breakers in an ocean surf, while her hands and features twitched as under the strain of a tumultuous, though half-suppressed agitation. In her attitude she gave the impression of trying to resist some invisible but over-powering force, against the influence of which every minute of her time had to be bought by unceasing struggle.

She pointed backwards over her shoulder, and as I followed with my eye the direction of her finger, I scanned a vast unconfined expanse of space where spectral forms seemed floating along currents of unceasing agitation as if under the resistless action of a mastering force, compelling its ghastly, wreathing, rebellious cargo to assume the definite attitude and momentum of a preconceived plan of adjustment.

Straining my attention, I observed that the uncanny creatures of this forbidding habitat were not only shifting their positions, but also forms and characters. Apparently in response to some internal impulse of feeling. their forms, now and again, with lightning-like rapidity projected some grotesquely exaggerated member of their plastic, jelly-like organisms. Lips would all of a sudden swell out into a hideous monstrosity, involving in its formation almost the entire creature. Similar changes occurred in other functions and parts of these constantly shifting forms. Ears, noses, tongues, etc., increased and decreased in size and character, portraying the entire range of progressive or retrogressive changes of moral life, and thus giving rise to a pantomime, at once hideous and interesting, in which every ruling emotion portrayed itself in the size and expression of the projected organ.

This ghostly carnival swept onward in a circling motion without a sound. I shut my eyes to gain a relief from the infernal performance, only however to realize that their objectivisation in my *optic thalami* did not depend upon the activity of my organs of vision. They belonged to the great class of what might be called optical "wireless," which depends on no external sensation for its manifestation, but appears as realities to every mind, attuned to a corresponding key of vibration.

Dante and Milton must have been able to sink their minds self-consciously and deliberately to these depths of existence, with which they seemed to have been as

familiar as with the topography and ethnography of their own native countries.

"This is my present home," said my unfortunate friend, "and here is where I experience the fate of Hamlet's dead father, who found himself—

"————confined to walk in fires
Till the foul crimes done in my days of nature
Are burnt and purged away. But that I am forbid
To tell the secrets of my prison house,
I could a tale unfold whose lightest word
Would harrow up thy soul, freeze thy young blood,
Make thy two eyes, like stars, start from their spheres,
Thy knotted and combined locks to part.
But this eternal blazon must not be
To ears of flesh and blood————."

"I burn," said my friend, resuming her weird tale, "yet the fire which consumes me is not the elemental destroyer which goes under that name on earth. It is a fire of anguish that consumes whatever of my nature that is destructive in this state of life. It is the fire of a fever—a soul-fever—weeding out and consuming the toxic elements of selfishness, the moral corruption, accumulated during a life lived mostly for self, and inspired by egoistic motives. It seems to divide or dissect the subtlest compound of my nature, as if the very atoms were laid bare and honeycombed. I experience the presence in my nature of a corrosive force pulsating through my consciousness, and eating away every tendency and desire that connects me with the sense-world. All notions of personal stature and advantage, all inclinations for sensual indulgencies, all fears, ambitions, envies, jealousies—every notion arising in my mind of being a separate, exclusive and self-sufficient being, with interests and hopes, ideals and destinies, which in any way distances me from my fellow-men—are being mercilessly burnt out by these ever-present, inescapable flames of searching, dissecting light."

She shrunk together, collapsing from the strain under which she seemed to labor, but rallying again, rose up and continued in the sombre pathos of the inevitable, at once expressing rebellion and submission:

"Oh, how little mankind realizes the mass of worthless ballast it drags along on the voyage of life, retarding and endangering its progress. Verily, we are sailing with a corpse in our cargo. I look upon my past life with unspeakable disgust. It seems to me almost as if it were void of every redeeming feature of positive unselfishness, of freedom from any taint of personal, self-seeking motive. And when all this final balancing and clearing-up business is over, how little is worth survival in the larger, eternal life of the liberated soul. All the strain for social benefits and positions, vanities of style, and impressiveness of stature, literary fame, political power, intellectual domineering, any ambition, any ideal, any hope; if only aiming at personal advancement in some form or other, constitutes a most horrid and unreasonable waste of life, time and energy. To love humanity in motive and service is the only legitimate expression of life. All the rest of life is forfeited, wanton, hopeless."

But her storage batteries of sustaining psychic energy were exhausted, and the stream of her communication seemed lost in the gulf-streams and whirlpools of emotions sweeping through this spectral abode. An invisible force, not unlike the suction at work in a vacuum pump, seemed to pull her backwards to the zone of dark phantasm from which she had momentarily escaped.

As her power of resistance weakened, the force of suction seemed to increase, until finally, tottering under the overpowering strain of this thousand-armed monster-force, she lost her equipoise, and suddenly, as if caught by a cyclone, was swept headlong away from my field of vision to re-enter the dominion of living phantoms.

The Trail Brightens.—For some time I saw nothing of my departed friend. My business of late had rendered my existence somewhat fluidic, and landed me for a season at the extreme end of the Scandinavian peninsula, in the little isolated commonwealth of *Haparanda*, which while the northernmost city of Sweden, nevertheless during its short, two months' long summer season, exhibits all the voluptuousness and fascinations of a tropical vegetation.

One evening in the heart of June, while sitting by myself on a granite boulder, a little distance out of town, with an intensely blue dome above me, and a dream-

land of verdure, flower and fragrance below me, with the lingering after-glow of a recent sunset illumining the towering mountain-peaks of the majestic Areskutan —the Sierras of Sweden—gradually my thoughts sank into the events of the past, pursuing in imagination the movements of the strange being, who while dead, still remained to me a living companion. For some time, however, perhaps three months, I had not seen her, and my interest in her unknown vicissitudes largely absorbed my mind during my leisure hours. All at once a cold shiver crept over me, giving rise to a sensation, which having no basis in the almost tropical temperature of my surroundings, flashed into my mind the idea of its possible association with the presence of my friend.

I mistook not. Before me stood the object of my thoughts. But ah! how changed. The fear, despair, and agony which at our last meeting were visible in every feature and every gesture, had been displaced by a lofty submissiveness and dignified repose. She looked at me with a full eye, expressive of at once tenderness and power, compassion and will. What a noble, superb animation, beaming with interior light, passionate devotion and irrevocable resolve!

"I am out of Inferno," was syllabled in my consciousness. "The grossness of my nature is removed, but my soul is still in the throes of birthgiving. Freed from the noxious weeds of selfishness and impurities in all its hydra-forms of life, I am at present placed under the action of an environment which compels my purged nature to develop entirely new and unsuspected powers."

She paused for a moment, as if to collect and formulate her thoughts. While waiting for her to continue, I noticed the change in her robe, which from the old shade of dark drab had assumed a color of cream, streaked with light blue.

"My evolution," she continued, "in this posthumous realm has hitherto been largely negative and eliminative, while at present it is passing over into a positive, constructive and organizing phase of consciousness. My soul is budding into self-consciousness, and my mind is beginning to wield a self-sustaining, self-determining power. But I shall try to put before you the factors at work in the process of my unfoldment.

"As a basis to start out from, I will refer to the life of ordinary humanity, where self-consciousness mostly consists in reactions of the mind to external impressions. The minds of the great majority of people are a blank on which gossip, sensations, sight-seeings, travels, accidents, stirring vicissitudes, etc., scribble down their incongruous contents. External stimulants in one or another form of sensation lie back of and support the entire structure of what goes to make up most people's actual self-consciousness.

"Now if sensation were suddenly to stop its generative processes, and not a ray of light or life be permitted to enter the mind through the agency of the five senses, what then? Would not the individual find himself in chaos and night, very much like awakening from a sleep when bereft of the powers of hearing, seeing and general sensation, a state of existence which corresponds to my own experience upon awakening from the shock imparted to me by the death of my physical body? I woke up dazed and bewildered, without any power to communicate with the order and expressions of life and consciousness peculiar to this supersensuous plane of existence, where consciousness manifests in terms of life quite different from what I experienced through the function of the senses. Thus being divorced from my sensory vehicle on which I had so largely depended for guidance in my subjective as well as objective existence, I found myself not only inadequate to deal with the intelligences of the new world, but also rendered powerless to reassume my interrupted relation with the old sense world.

"Yet here are some phases of this subjective after-life to which I have been able to respond—phases related to the emotional forms of imagination with its selfishly passional and sentimental indulgences so characteristic of sense-life. Hence, every notion associated with forms of fear, worry, anxiety, envy, dislike, desire, vanity and unbrotherliness or selfishness, in any of its thousand-tongued expressions, constituted the only stock of my available knowledge responding to my power of recognition—a fact

which opened up to me the morbid contents of the awe-inspiring *inferno*, which in spite of its hideous dwellers represented in principle the main expression of the life with which I had retained familiarity. Everything else was largely a blank, on which I now and then discovered flitting presences of transfigured beings diffusing pulsations of a faintly palpable zone of holiness.

"For only such stages of consciousness, with which we have the power personally to identify ourselves during earth-life are recognizable during the immediate stages following death. Powers and qualities are not generated through the mere change called death; nor do the eternal laws and principles of the universe suspend their operations because an individual passes over from one state of existence into another.

"'As below so above,' said Hermes: In Heaven or on Earth—in life or after life—we are that and no more, which we have attained to through self-conscious exertion in the one or other direction.

"And as the character of man is expressed in his form, so the quality and power of his soul can be traced in the influence they exert on his physical evolution expressed in his demeanor and attitude to trials and vicissitudes of general existence.

"I am now developing subjective consciousness, *i. e.*, the power of the mind to reflect and verify life and its meaning in perfect independence of sensory or functional aids. Had I been given less to social functions, less to outer, sensational, transitory and purely personal interests, and in place devoting my time and power to cultivate acquaintance, through meditation and aspirations with my own soul, I should find fewer obstacles to overcome in my present state of evolution."

Notwithstanding my friend's austere denunciation of the manner in which she had spent her physical life, she was not by far as much "given to social functions" as are the great majority of our society ladies. But she was not without a fondness for gossip, and enjoyed plunging into the social swirl with all the enthusiasm of her sex. It was for the first time, in the after-life, that she learned to appreciate the full meaning and value of time—an appreciation which came out with full force in the ardor of her self-disapproval.

"In what way do you develop your subjective powers in your present state?" I queried in my mind.

"Ah, by enforced, absolute solitude and silence. Look at that endless, solitary trail leading on, and on, surrounded by sterile rocks without a spear of vegetation, or a motion or wingstroke of animated existence. Silence of death everywhere, or perhaps more correct, the silence of a new, higher, but as yet inexperienced life. I feel compelled, by some resistlessly directing inner power, to pursue this terrible, endless destiny without companionship or semblance of life and consciousness in any form. My sense-nature is absolutely at rest, being bereft of every opportunity to assert itself, and without any means of self-preservation—thus compelling the impersonal, supersensuous soul-nature to unfold its slumbering powers. For it is in the arrest and silence of the animal life that the divine life arises to the surface through channels and media formed by the new and greater demand on life, to yield a higher and purer expression. For like any other force or energy, the stream of life follows the lines of least resistance. Hence, as in my present mode of existence, the pursuit of the purely supersensual—thought and feeling, uncontaminated by sensational representations—offers less resistance to the soul than any other line of advance, it follows that the growth of my divine nature is irresistible even though the process of unfoldment proceeds slowly and under the stress, not to say the agony, of a veritable spiritual birthgiving. For what is growth but a series of birth-givings, by which the old modes and expressions of life are giving way to new and higher ones, more adequate to the enhanced and intensified presence of spiritual consciousness.

"Now, Gerald, I ask of you a favor of friendship and faith. Be my conscious and unfaltering companion in this soul-stirring, life-refashioning solitude. Send me thoughts of cheer and hope—in fact be with me as soul. Form in your mind a strong picture of my situation, and place yourself in thought by my side.

Tell our mutual friends to do the same. I almost feel too weak to carry out the task of my glorious evolution. Like a plant removed to unfamiliar environments with which it has to struggle to reestablish its elemental adjustment, so my soul in its new environments feels itself trembling in the balance, between something new, urging its right to live, and an old, refusing to surrender its hold on life."

The last words came to me as if in a whisper. The force enabling her to sustain the undoubtedly very severe strain involved in her concrete communications, was exhausted, and with a gesture of parting and a smile of hope she withdrew from the scene, floating away in a sphere of subdued light, evidently to resume her trail of conquest and discovery along avenues of undreamt-of realizations.

And this forms my last direct communion with that released soul. Yet twice afterwards I have had glimpses of her presence, though for each time she appears more remote from my own stage of evolution. Each time her garments seemed brighter and more ethereal. The last time I saw her, she appeared to me like a being of light, transfigured and luminous, "trailing clouds of glory," as she floated seraphically in the radiant zone of an indescribable superspectral azure, seemingly in possession of the "blue flower" of immortality—the imperishable price of spiritual life, for which she had been suffering so much pain with so much patience.

But must we consider this departure of the human soul into new and undreamt-of spheres of life as identical with a final closing of the individual's mundane experience? Shall our lives henceforth be spent under unequal terms of evolution and remain incapable of yielding new opportunities of love and service through personal identification?

With regard to this momentous quest—propounded by every feeling, loving heart during all time and ages—I feel unshakably calm and affirmative. I have her promise of reunion, somewhere, somehow. She has whispered in my heart that such a union may not require for its immediate theater the ethereal beyond, but be reached on this earth, in the very midst of concrete life. I am inspired with the consciousness that we may meet, and shall meet, in the mutual pursuit of new truths, new ideals, new realizations, new possessions which may require corporeal conquests for their attainment; face to face, and heart to heart, with the palpitating, surging, rising and falling waves of an ever moving ocean of humanity. For may it not be that the priceless pearl of truth is to be found only at the bottom of life, in the crevices and nooks of personal, concrete, face-to-face experience.

Back of every price is conquest; and there is something in the depths of my consciousness that affirms that Earth, with all its sadness and sorrow, its tragedy and farce, has possessions—vital and indispensable—which can be won only by a conquest of treasures, bound up and hoarded in the very bosom and vortex of mundane vicissitudes. It is the old legend of Siegfried, the Nibelungen, having to pass over slain dragons and outwitted giants to find his Rheingold. And while earthly existence, even in its highest form of evolution, may never yield opportunities for final perfection, yet it may furnish conditions and modes of existence, without which the towering eminence of spiritual self-consciousness, with its timeless and changeless consummation would only remain airy abstractions.

And furthermore, may it not be, that in the recurring phases of alternating concrete and abstract existence—objective blossoming, subjective fruition, with the soul drawing sap and sustenance from its organic and vital contact with earthly conditions by repeated evolutionary sojourns—is found the *modus operandus* by which the soul is enabled to transmute the crude elements of human virtues into the imperishable powers and felicities of changeless, timeless, and deathless beings.

German and American Physicians.

There does not seem to be much difference in the average income of German and American physicians, as owing to a report by the Medical Chamber of Berlin and Brandenburg the average income of Berlin doctors is $2,250 per year. It seems, though, that in the case of one thousand three hundred and twenty-two of them the yearly average is less than $1,250.

The Relations of the Science of Chemistry to Medicine.

BY HOWELL B. GWIN, M. D.,

Nashville, Tenn.

Science Is Organized Knowledge.—We have natural and physical sciences, treating, respectively, of the outer and inner constitution of matter. Chemistry, or the study of chemical force, treats of the constitution and changes of matter, determining these by analysis and synthesis. Medicine deals with the cure, alleviation, or prevention of disease. Its main pillars are anatomy, physiology, and chemistry.

Medicine and chemistry, strictly speaking, are not recent in their origin. The oldest books of the Jews, Greeks, and Chinese contain records of their use. In every science there must first be a period for the collection of facts, a period of chaos, slowly yet surely dismissed by the majestic command of reverent students, "Let there be light," and followed by the reign of classification. No science in its practical results can be absolutely exact or perfect. Generation after generation it grows, by the elimination of the false and the acquisition of the true. Projecting its theories as so many working hypotheses, true science is grounded only on facts, but happily unexplained, unclassified facts are yet beneficial.

Chemistry and medicine stand closely and practically related. Chemistry is a larger and more independent science than medicine. It may be said that the former is a generalism, the latter a specialism. It is the province of each to furnish facts to the other for use or explanation, and to both thoughtful physicians ever address questions. When chemists exhibit substances with definite properties, physicians reflect, "Can these avail in medicine?" Pathologists present the characteristics of an epidemic, physicians ask chemists, "Can you add to *materia medica* an antidote of the causative poison?" Thus their interdependence appears in this era when sciences have been more correctly formulated and more closely interwoven.

Chemistry Aids Medicine.—First, in the study of the chemical structure of human tissues.

In late years, Chemistry has given vast information respecting the composition of the human system. The anatomist in locating the bones, muscles, organs, etc., is fired with a desire to know their constituent elements. The physiologist in studying the functions of the body is possessed of the same burning desire, deepening into a demand for essential aid from the chemist. The chemist fraternally responds by revealing the constituents, proximate and ultimate, of the frame, its organs, and its fluids. He defines the presence, degree of union, and the value of these elements which secure to this "fearfully and wonderfully made" being such balanced and multiplied offices as solidity and flexibility, hardness and softness, opacity and transparency, sensibility and insensibility, and motion voluntary and involuntary. No analyses within the range of chemical experiment are so difficult, so instructive, so beautiful as those which fix the composition of the blood and the various secretions which aid in its manufacture or facilitate its work. Through what painstaking, toiling research, and close-knit reasoning and experiment themselves an inspiration and example to the physician—the physiological chemist is annually enriching our medical science. Without chemistry the eyes of the physiologist are blinded as if by a cataract, his steps hindered almost as by a ligature.

The tissues, the blood, the secretions and excretions are chemical compounds. Physiological processes are chemical reactions. The mere circulation of the blood is brought about by mechanical means, but the source of the propulsive power is a chemical process, and the circulation has for its end and result a chemical reaction.

To specify: respiration is a true example of combustion. The seat of combustion—which is simply a process of chemical combination—is the lungs. The substance burnt is sugar. The products are carbonic dioxide gas and water. Every man then is a small chemical laboratory. Our bodies are furnaces continually burning, whose fuel is our flesh, and whose smoke is the breath of our nostrils. In every muscular effort, whether a blow, a breath, a word or a

step, a portion of the tissues concerned undergoes this chemical change, and motion, voluntary or involuntary, can no more be produced in the animal body without a combustion of its tissues than it can be generated in a steam engine without burning fuel under its boiler. We do not create the force; we do not originate it; we merely excite it. Whence, then, the source of this force? This question will be answered under another division.

Armed with such weapons from this scientific arsenal, the medicist draws his logical inferences as to the remedies he requires for external or internal use; and these are chemical compounds whose effects, not yet well understood, depends upon chemical reactions.

Chemistry Allies Itself With Medicine, in the discovery of medicinal properties in substances.

Of all departments of medicine, chemistry promises the brightest future. Once chiefly analytical, it has become enthusiastically synthetical. The future growth and triumph of medicine depends upon the new unions of what has been called, perhaps unscientifically, organic chemistry. Already it has accomplished wonders, and the introduction of antiseptics and anesthetics into the practice of surgery and obstetrics mark one of its greatest triumphs.

In its yearly contributions to *materia medica* it shows that there is virtually no limit to the substances which can be made. A celebrated French chemist has made a calculation with acids of certain alcohols. He says, if you gave each a name, allowing a line for a name, then printed one hundred lines in a page, and made volumes of one thousand pages, and placed a million volumes in a library, you would need fourteen thousand libraries for your catalogue. He, therefore, properly calls such bodies infinite, instancing the synthetical construction of the alcohol and aldehyde series, of the organic acids, of the amides, of urea, and of the millions of possible bodies which loom in the future—certain to be made, waiting to be made, the possessors of qualities suspected or unsuspected, but unknown.

What scientific physician believes that all anesthetics have been discovered? Chemical reasoning suggests that by rapidly making one hundred inspirations per minute we effect temporary anesthesis sufficient for the extraction of teeth without pain—that bisulphide of carbon may be used to relieve headache—that chloroform and ether in equal parts may safely be entrusted to a wise physician in violent cases of neuralgia—that, all honor to Pasteur, these latter may put in temporary abeyance an incurable disease, like hydrophobia, in its progress deathward.

Awaiting the revelation of the chemist are specifics for diseases. At present quinine seems to be the only remedy which may approach the title of specific—though some have given this title to cod-liver oil. The probable provision of the Supreme Physician of many specifics has doubtless often occurred to the mind of the toxicologist who has been so largely guided and blessed by chemistry, aye, whose occupation, like "Othello's," would be "gone" but for chemistry. To chemistry we may hopefully look for the discovery of specifics for cholera, diphtheria, scarlet fever, yellow fever, and certain zymotic diseases which are now so little under our control.

At present the exact chemical value of agents to the human constitution is known as a series of ultimate results. The real *modus operandi* of many of the most powerful is yet unknown. The chemist is investigating this, and, through the aid of his test-tube, crucible, etc., and of the microscope, and of comparative physiology, this problem will not show itself insolvable in the face of many another, once as difficult, which has been solved in his and other fields of investigation.

With his prime object to develop his science rather than limit it to the aiding of medicine, the chemist is better able to explode old theories, to discover discrepancies between facts supposed to be established, and to multiply his contributions to *materia medica*. It was the result of the labors of professional chemists that we have added to our pharmacopœia so many remedies, notably, chloral and salicylic acid. But sometimes the very romances of experimentalists bring benefit—as when alchemy, which, as Liebig has remarked, "was never at any time differ-

ent from chemistry," besides having gained a knowledge of the properties of bodies, contributed mercury to our *materia medica*, and also as when the modern evolutionists enlarge our knowledge of the parasites that infest our bodies, which knowledge has already modified sanitary regulations in a remarkable manner, and will force into the hands of superior physicians the microscope and test-tube to answer questions once unanswerable, though on them hang issues of life and death.

(To be Continued.)

The Evolution of Tyranny.

BY JOHN A. WELSCH, M. D.,
Farber, Mo.

At no time in the history of the human race has tyranny ceased to exist, the difference being in degree, and nowhere is the truth of this statement more vividly demonstrated than in the history of the medical profession. The first physician to use chloroform for the relief of labor pains in Germany was banished from the empire under the charge of violating a scriptural quotation in relieving pains of this character. The tyranny in our profession is manifested largely in sectarianism, and physicians are banished from medical societies and called quacks and charlatans for disagreeing with the opinions of a certain combination of doctors (?), and they proceed to organize legislative committees whose duty it is to secure the passage of laws in the various States placing the liberty of all physicians in the hands of a few appointive politicians. If you wish to know how successful this giant medical octopus has been, read the statute of your own State, which pretends to be a law to regulate the practice of medicine, but which really establishes a medical tyranny in your State not equalled by any of the edicts of any Czar in existence. Physicians have a right to demand (when accused) a trial in the established courts of the land. But the octopus wills that a certain small coterie of political appointees shall be your accuser, judge and jury at their own pleasure. They can ruin, in no time, the reputation you have spent a fortune and the best years of your life to obtain, and you have no recourse under the law. Of course, these statutes are unconstitutional; because the constitution emphatically says that no citizen shall be deprived of life, liberty or property without due process of law. And the elimination of a competitor by revoking his license is not a process of law, but only a manifestation of the evolution of tyranny. Because a license to practice medicine is liberty, and the exercise of this liberty or privilege becomes property. But testing the constitutionality of a law is not within the province of the average physician, because he has not the funds, and the tyrants usually prey upon this kind. They do not attempt to impose their authority upon the wealthy or powerful; no difference what kind of a physician he pretends to be (magnetic healer, chiropracter, or what not), but usually the more humble members of their own special sect. A medical friend, who was suffering persecution at the hands of these petty tyrants, writes me that he is past middle age; has been practicing his profession for thirty years, but excited the jealousy of a member of the State Board who resided in his vicinity in the city by being more successful than the board member in certain diseases. In this particular instance the disease was appendicitis. The persecuted party cured it by electricity, and other remedial agents. The tyrant asserted the only remedy was a surgical operation (larger fee), and the victim was promptly notified to appear before the board and show cause why his license should not be revoked. He finally, however, secured a permanent injunction against the tryants. You will see in the lay press and medical journals that the State Board of Health meets at a certain place to examine applicants to practice medicine and consider charges against certain physicians. In this way they pretend to the people that they are doing something, and keep the rank and file intimidated, because most physicians have courage enough to think a little on the sly, and may have at some time prescribed a remedy for the benefit of their

patient that had not been approved of by and of the councils who are the makers and compilers of all ethical (?) lists of therapeutic remedies, and, of course, if you consider the patient's good in preference to their wisdom, you may be their next victim. I am convinced that most physicians, and all conscientious ones, are guilty of this violation of the code, but they do not mention it when attending a society for the promotion and extension of the self-declared great ones. Even the headquarters of medical tyranny in America are shocked by having one of their members read a paper entitled "The Fetich of Disinfection," and when they hear from the people, and the rank and file of the profession, somebody will be compelled to work for a living, and another stride will have been taken in the evolution of tyranny.

[Written for the MEDICAL BRIEF.]

The Three Hypos Prefixed to the Great Thesis of Cosmogony.

BY J. C. DENSTEN, M. D.,
Scranton, Pa.

Among the various hypotheses of creation, not only of the cosmos or universe, as a whole, but pertaining more particularly to the earth and its biological factors; is the intent and purpose of this article.

Let us then begin with the creation of the earth, upon which we live and have our being. All knowledge gained upon any subject is centered about that subject, and is called science. We therefore term as "sciences" many obvious and abstruse subjects, whether occult, esoteric, or material, to which any line of reasoning or logic may hypothetically or otherwise be applied. All sciences are divided into the exact and inexact. Exact knowledge is absolute and demonstrable. Inexact knowledge is probable and approximate.

Many theories are advanced concerning the various phenomena of nature, and the knowledge gained upon scientific subjects, is, in most part, derived from observation, and absolutely so as pertaining to geology and astronomy.

These two sciences are the potential factors toward knowledge, as pertains to the creation of the earth, its component parts and its evolutionary state and stages, its proximity to the sun and surrounding planets, its suspension in ether, its magnetic force, and the laws governing gravitation, etc. This brings us to the "Theories," concerning the three (3) hypos of creation:

1. The hypothesis of eternity.
2. The hypothesis of creation.
3. The hypothesis of evolution.

The mind of man is the key to every solution. Theoretically, the mind of man is very productive of hypos and theses, which, clothed with logic and reason, become axioms, and so, step by step, every science is built upon a tower of truth, an exactness undeniable and convincingly true.

The minds of men vary. The reason and logic of one mind may be sophistical, while another may reason by axiomatic deduction or induction, yet both, seemingly, appear sound in reason and logic. The one will, from his sophistical premises, produce a reasonable and logical answer, viewed either—*a priori* or *a posteriori*—and be recognized as sophistry only by a mind able to reason and logicise axiomatically. The "hypothesis" of one is false, of the other true. In order to become a judge, one must be learned equally or superiorly to the one judged, else how can he be recognized as a competent critic?

It has been said, "that all men look upon the same world, but all men do not look upon the same world alike," and surely, this is true. The five senses vary in results, as minds vary in results. Blue to one optically appears green, while to another green may appear blue, and thus the senses are deceived and sophistical reasoning deduced. Sounds also vary, as do the feelings. One may look upon a sight with composure, while another may be filled with terror at the same spectacle. Because of such variations, physiologically, in man, so specialists have sprung up in every branch of trade, professionally, artistically, mechanically and scientifically. Therefore, we rely for a more exact knowledge on the "specialist" in his or her particular branch of trade, thought or business; and, as considering

the different hypotheses of creation, as in other departments of knowledge, let us seek the "specialist," in whose opinion and reasoning we have more confidence than in that of the public in general. The "specialists" to whom we are now to look, and on whom we are to depend, are those learned in and devoted to the subject before us, viz., the truth concerning the earth's creation, and all biological forms, both flora and fauna.

1. *The Hypothesis of Eternity.*—This belief has possessed, and still possesses, many minds as the true solution to the problem of creation. That all things existed eternally, there being no beginning, and with the same applied belief of the future—that it will always remain and be throughout future—eternity. All believers in this hypothesis also believe in a creator; a being, or power, capable of producing and maintaining all that appears in the universe, and the earth in particular. They recognize laws by which all things are controlled, but believe in special providences, affecting things material.

2. *The Hypothesis of Creation.*—And now we are treading upon sacred ground. All our present institutions, or, at least, the majority of them, universities of learning, churches, law, judiciary, civil and criminal, of equity and of trust, are all founded upon this—the hypothesis of creation. From this belief sprang the Old Testament, which for four thousand years has been held sacred and true. From this hypothesis Jesus of Nazareth, maintained to be the Son of God, and lived accordingly; hence, having the courage of His convictions, was crucified, then idolized, then deified, and for nineteen hundred years all other hypotheses have been overridden by this one great theory—the hypothesis of creation.

Those who believe in this hypothesis are in the majority; they believe that all things were created by the fiat of a Prerogative, and that power they call God. Many and varied are the concepts formed of this Creator. Many humanize Him, and picture Him fantastically, as sitting upon a material throne, over-ruling the affairs of the world; such "fantasms" are varied and great. They believe that this "Creator" has the power to make or destroy, to calm the waves of the tempest, or create something from nothing. They attribute catastrophies to His displeasure or wrath, and yet they call Him a God of love. They worship Him as an individual God, and expect personal favors. They fear Him, yet claim to love him. They worship Him one day in the week, in "spirit and in truth," and cheat their neighbors all that it is possible the other six. They believe literally in the wording of the Old and New Testaments, and die in ignorance of truths outside their Bible. They call all knowledge sophistry which does not accord literally with their word of God. They still believe that Joshua commanded the sun to stand still, giving proof that they have not passed beyond the theory of Ptolemy—the geocentric theory, believed centuries before Christ, but now exploded, since Copernicus gave to the world his heliocentric theory, for the advancement of which truth Bruno lost his life, and Galileo was imprisoned, persecuted and banished. They disdain to read "scientific works" by Laplace, Kant, Lamark, Wallace, Darwin, Spencer, Huxley, Tyndall, or Hæckel, fearing, perhaps, to be too strongly impressed by sound reasoning, and the axioms of nature, as compared to their belief of faith and fantasy.

3. *The Hypothesis of Evolution.*—By evolution, we mean the evolving out of itself, the unfolding from within a succession of things from a beginning; a greater from a lesser, as the rose from the bud, or a frog from the pollywog, or man from the ape, or the earth, as it is today, from a nebulous mass. The theory of evolution is a wide field for thought; in it are included geology, biology, meteorology, paleontology, astronomy, natural history, morphology, ontology, ethnology, and many other sciences, all of which harmonize and aid in proving the theory. In fact, there is no other theory so well proved and substantiated as the theory of evolution, concerning all material things.

Concerning the evolution of the earth, the nebulous theory holds positive evidence. New worlds are being formed from nebulæ thrown off from the sun, the residue of previous worlds. The telescope, astronomically applied, gives us positive knowledge of this fact, for it displays to

the sight worlds in different degrees of formation.

That this earth was once in a gaseous state is quite evident from "induction." That millions of years intervened between its beginning and the stage in its evolution which made it habitable, or the stage or condition made possible to produce and sustain animal and vegetable life. Then millions of years again to produce the present flora and fauna. But step by step have the scientific "specialists" in geology, biology, astronomy, meteorology, morphology, paleontology, and ethnology, studied and compared notes, and formulated facts in each department of science, until it was found and proved beyond doubt that each fact in the aggregate pointed with the same unerring certainty to the same result, the same answer, and that answer and result spelled the same word—e-v-o-l-u-t-i-o-n.

If, then, the theory of evolution be true, where shall we seek for "the beginning of life." What is life and how did it originate? That question has never been solved, has never been satisfactorily answered.

Evolutionists deal with cause and effect, with existing states, linking the past and present together by deduction and induction and comparisons. Missing links are often wanted to complete a chain of evidence, and in many cases these have, at last, been found, thereby completing the series.

But the theory of evolution is yet in its infancy. It is true that for several centuries a very few minds have dared to step aside from the orthodox principles and dogmas of their day and generation, and assert with boldness their belief in the hypothesis of evolution.

For centuries, in the Medieval ages and down to the nineteenth century, "religion" fought against "science," and prevented its advancement. Then came four men, born within a radius of twenty-five years, who gave their time and best thought to science; each going his own way, but, ultimately, converging into the same fountain-head of knowledge and conviction; men who did more for advancement of scientific knowledge and truth and facts than any others in the century just passed. I refer to Darwin, Huxley, Tyndall, and Spencer. One other deserves mention—that of Earnest Hæckel. They spake and worked, and their works shall live for knowledge, to make more wise the coming generations. They have touched the little grain of thought upon the mountain top of "evolution," and started it rolling down the mountain side, toward and through the valley of investigation. This little grain of thought will touch another, and they another, and these other and greater minds until the whole world will be rolling and crashing, intellectually, into the valley of science, of knowledge and of wisdom; sitting at the foot of the mountain of evolution, like Paul at the feet of Gamaliel, to learn more of its truths—more of the science of the theory of evolution.

What produced life? What is animation? Here lies a mystery still. What produced matter? What is inanimate substance? The solution to these questions also remains a mystery—we do not know. We can theorize and postulate, but the mystery remains, and our syllogisms are incomplete.

Evolutionists, proper, do not deal with these subjects, nor do they endeavor to solve this mystery. They take life as they find it, and the remains of life as it has been, and reasoning from cause to effect, and from effect to cause, determine accurately, past, present, and future conditions. From the known facts they theorize with a degree more or less of certainty, and every "thesis" shadowing of "theory" becomes hypothetical; hence, the theory of evolution is yet but an hypothesis.

It may be said, and creditably, too, of the leading specialists on evolution, that they have been honest in their researches, and have given to their contemporaries and successors as plain and logical an accumulation of facts as it were possible under existing circumstances. They have dealt more in facts than in postulates, and have given invaluable testimony, derived from observation, toil, study and investigation. Facts are given as facts, theories as theories, and, as to the origin of life, they remain agnostic; they leave the solution of that problem to the biologists and theologians, and will accept or reject their solution, according to reasonable and logical convictions and proofs, as the biolo-

gists and theologians have and do accept theirs.

The cellular theory of life accords with evolution. The protoplasmic formation of a single cell, then the proliferation and continuity; one a plant life (plasmodo mous, the other an animal life (plasmophagous). From these, single life-cells have been produced by evolutionary processes, aided by immeasurable time, up, up, up, through the different forms of plant and animal life to the present state and stages of flora and fauna.

On the animal side, from water animals, developed, in course of time, the amphibious, or those capable of living both on land and water; then land animals with lungs, as reptiles, and from these evolved birds and monkeys; then the gibbon, orang outang, chimpanzee, gorilla and man, and will it cease here? Not if evolution be the correct theory. There can be a great improvement yet on man, and I, for one, believe ages will yet produce a superior being to the present man, so high about the present man as man is now about the gibbon, or others of the ape family.

One fact is certain, that the chemical laws of production will continue, from combination of colors, to produce varied and variegated complexions in the human, as in all animal creation. The so-called white race is not white, it is ruddy (red), but in the coming generations of human production there will appear a generation white in color as chalk, just as in chemical nature it requires the united combination of all the colors to produce white, so the united combination of all colors and races of human beings in marriage will, eventually, produce to progeny, through heredity and, as a result of an atavistic law, a perfectly white race of human beings. That time is a great way yet in the future, but it is inevitable. There will also be produced in the future a hairless human being. There will yet appear a race of humans without hair on any part of the body, and that will occur when the physical has reached a distance sufficiently remote in the future to have perfected the now progressive evolutionary laws of physical changes, dating from the origin of man's existence, when his entire body was covered with hair.

It requires millions and millions of years for any very great noticeable change—epochs, composed of ages of time.

The biblical account of creation, as chronicled in the first book of the Pentateuch, infers that but six thousand years have elapsed since the creation of man. Paleontology proves that mankind has existed for millions of years.

The Hebrew account of creation was taken from the Babylonians, Chaldeans and Assyrians, and are, in most part, if not entirely, legendary, traditional and mythological. It is claimed by theologians and biblical commentators that Moses wrote the first five books of the Bible, known as the Pentateuch, but scientific and unprejudiced minds have, after careful investigation, proved conclusively that neither Moses nor Joshua wrote any part of the Bible, they having been dead at least three hundred years before these books were written.

Scientists tell us that some time in the future of the world, it will cease to revolve, either on its own axis, or around the sun, in its orbit; that, as it grows older, it becomes larger, by the accumulation of meteoric particles, and dead and decaying matter from its own vegetable and animal productions on its surface. That the earth, once being smaller, moved faster, and at one time but five hours being a day, and, gradually enlarging, it revolved slower until now twenty-four hours mark one revolution on its own axis. This slowness will continue, less and less; the slower it moves the less heat is generated, or, in other words, the earth gets colder, until in the coming ages it will become so cold as to exclude vegetable and animal life on its surface; then, later, will drop back into the sun, whence its particles and gases will again be thrown out into space, to become a nucleus, or nuclei, for a new world, or worlds, in accord with the nebulous theory of their formation. But, intermediate to final dissolution of the earth, there may yet appear several glacial periods. Scientists estimate that we are now advancing toward another glacial stage. Ten thousand five hundred years hence and the "glaciers" will have advanced

upon us, from the Arctic region, all our rivers and streams will become ice, and "glaciers" one thousand feet high will slowly encroach upon us, crushing our cities beneath their weight, and reducing to fineness all material things above ground. All animal and vegetable life in the region of its environment will die, and then in an eon of time, the extreme cold will again yield gradually to changes of temperature again sufficiently warm to sustain and reproduce both animal and vegetable life; "cycles" of time—like causes producing like effects in future, as in the past; history but repeating itself.

Materialism and Pantheism find virgin soil for prolific growth in the hypothesis of evolution, and surely the laws of nature construct, destroy and reconstruct. This has been going on from the foundation of the earth, and with each succeeding revolution around the sun there has been an increase in its size, a change of surface form, a change in magnetic force, an alteration in both flora and fauna, physically and otherwise. These changes have been slow and gradual, so slow that in many instances ages elapse before such changes are noticeable to the observation of man. But long epochs of time have produced changes convincingly undisputable. New genera and species have been produced, atmospheric conditions entirely reversed, and the physical earth entirely remodeled.

How are these changes brought about? Are they a special production from the hands of a creator, or are they the outcome, growth, and production of certain, and material, and natural laws? They must be produced either the one way or the other. Materialists and Pantheists see the creative power everywhere in nature, and recognize both the creative and destroying power in nature's laws; this power they may or may not call God. The Pantheists, as the name implies (Pan—all, and theos—God), sees God in everything, and believes He is omniscient, omnipotent, and omnipresent, but the concept of their God differs from the concept of the God of the Christian, in that it observes only law and order, while the Christian believes in his God as a specific God, with special providences, and an immortality. The Materialists believe in the laws of nature only, and hence are true evolutionists.

All the "isms," like the "pathies," are verging into one; they are dovetailing and uniting. Later, there will be but one school of theology, one school of medicine; these each will have swallowed up all others, and will contain the good, the true and the tried of all. There will be but one "ism," and that may be evolutionism; but one "pathy," and that may be electropathy, for electricity is light, heat, power and life. Evolution is reasonable, logical, rational and axiomatical, and corresponds with nature's ways of life and decay.

Greece Honors Doctor.

DR. ROSE, MEMBER OF MEDICAL SOCIETY OF ATHENS.

Dr. Achilles Rose, of No. 126 East Twenty-Ninth Street, has been elected the corresponding member of the Medical Society of Athens in recognition of his labors to reform the technical medical language of physicians. This society is one of the leading medical organizations of the world. In honoring Dr. Rose, the society said it considered him the first physician who had successfully reformed "the corrupt medical onomatology." All other reformers, according to the society, did not come up to the standard, as they showed a poor knowledge of the Greek language.

In speaking yesterday of reformed onomatology, Dr. Rose said the study of a language like the Greek should not confine itself to the investigation of either the ancient or the modern to the exclusion of the other. One complements the other, and both should be considered, he said, to make possible scientific knowledge of either.

"One would think that this was clear to everybody, and that especially the men of science would follow this rule in the course of the study of a language," said Dr. Rose. "Indeed, they do in the scientific investigation of all other languages than the Greek. In studying and teaching Greek our college professors are unscientific, and they have a conspiracy among themselves against scientific truth in regard to Greek. The philologists outside of Greece, who know only the writ-

ten tradition of Greek, call all words spoken in Greece to-day which they have not found in the old texts new Greek, and regard them as not belonging to ancient Greek, notwithstanding that in reality these words and phenomena are genuine, unadulterated, and often unchanged, oldest Greek.

"The importance of correct onomatology is that it furnishes the real instruments for the operation of the mind; it is important that these instruments should be of the best, and it is indeed working in the interest of science, for the progress of science, when we exert ourselves to improve our onomatology.

"Since the words preserve the ideas and transmit them, perfection in science is impossible without perfection in language. However true the facts may be, however correct the ideas developed by facts, only wrong impressions will be transmitted so long as the expressions by which they are communicated are not exact. I have heard it said that a reform in onomatology would cause inconvenience. This, of course, can not be considered from a scientific point of view.

"However, there need be no fear of inconvenience. Scientific onomatology will do away with much confusion and dispute which exist on account of improper terms.

"In many instances nomenclators of modern times have gone astray by creating unnecessary words, and by violating the laws of analogy and orthography. Irregularities in the formation of new medical terms have been permitted an extensive field because physicians of recent periods have more and more abandoned language study.

"While grammaticians have thus far done very little in presence of an existing animosity against scientific language in medicine, the innovators have carried their audacity to such a point that medical onomatology threatens to become before long entirely unintelligible. The Greek of to-day, as taught in the schools throughout Greece, the official language of the government of Greece, is pure Attic Greek, as pure as it ever was. It is the immortal Greek in all its youth and beauty, free from foreign elements.—*N. Y. Tribune.*

Examination Questions and Answers Missouri Medical Examining Board.

(Continued from page 488.)

MEDICAL JURISPRUDENCE.

Answered by Dr. Wesley E. Taylor.

1. What is tyrotoxicon, and in what is it found?

ANSWER.—A poisonous ptomaine, occurring in stale milk, cheese or ice cream.

2. What are ptomaines, and in what found?

ANSWER.—Alkaloidal poisons, the results of the putrefaction of animal matter.

3. What is insanity?

ANSWER.—A pathological condition of the mind in which it departs from that which is recognized as belonging to a normal person.

4. Give different forms of insanity.

ANSWER.—This is very difficult, because there are so many different classifications. One good one is: (a) Hereditary form, (b) insanity due to environment, age, sex, etc.; (c) insanity due to fatigue, (d) insanity due to infectious processes, (e) insanity due to toxins (as alcohol, cocaine, etc.), (f) traumatic insanity.

5. Give appearance of gunshot wound at entrance, and at exit.

ANSWER.—At entrance—small, depressed, smooth wound, with possible powder burns and clothing pressed into wound. At exit—larger, protruding, rough edged, free of clothing shreds.

THERAPEUTICS.

Answered by Dr. Wesley E. Taylor.

1. Give therapeutic action of aconite.

ANSWER.—A cardiac depressant, lowering blood pressure and temperature on account of dilatation of arterioles. Used in certain fevers.

2. Therapeutic action of belladonna.

ANSWER.—It is stimulant, analgesic, anhydrotic, mydriatic, and relaxes spasm and rigidity.

3. Therapeutic action of digitalis.

ANSWER.—Has a good diuretic action, diminishes dropsical conditions, and as a heart tonic stimulates inhibitory nerve fibres, slows heart action, but increases its force.

4. Therapeutic action of opium.

ANSWER.—It is a hypnotic, sedative, anodyne, antispasmodic and diaphoretic. Its action is best known as used for pain, or as a motor depressant in diarrheas, etc., and in peritonitis, vomiting, etc., etc.

5. Therapy of nux vomica.

ANSWER.—Tonic—to increase appetite; as a cardiac vaso-motor stimulant, and as a stimulant to respiration.

6. Therapy of veratrum.

ANSWER.—Reduces blood pressure, and acts as cardiac sedative, slows heart, and lowers blood pressure.

7. Therapy of mercury.

ANSWER.—An antisyphilitic and a sorbefacient; an alterative tonic, stimulating secretions; a purgative and an antiseptic.

8. Give medicinal treatment of measles.

ANSWER.—Isolate and give eliminatory and symptomatic treatment. A mild tonic is good.

9. Medical treatment of scarlatina.

ANSWER.—Quarantine; good ventilation; diuretic and eliminatory; gargles, if necessary; symptomatic, tepid to warm baths; oil skin during desquamation.

10. Medical treatment of diarrhea.

ANSWER.—(This question is rather vague). Remove cause, cleanse system of irritant, rest

in bed, diet, mild astringent; possibly, a mild opiate. Each case is a law unto itself.

HYGIENE.

Answered by Dr. Wesley E. Taylor.

1. What are necessary precautions and length of quarantine in (a) variola, (b) scarlatina, (c) diphtheria, (d) yellow fever?

ANSWER.—(a) Rigid quarantine, and continue seven days after scabs have fallen. (b) Quarantine until desquamation ceases, but keep well greased all the while. Bathe in tepid water and carbolized soap until all desquamation ceases. (c) Use antitoxin; isolate as long as throat is sore, some say as long as bacillus persists. Immunise all who have been exposed by antitoxin. (d) Protect from any mosquito bites, and keep thus isolated or protected until fever is all gone.

2. Give composition of milk. How sterilized. How peptonized. How modified. Why is it necessary to modify for infant feeding?

ANSWER.—Water, more or less, eighty-eight per cent; proteid, more or less, three per cent; sugar, four-fifths per cent; fat, three and one-half to four and one-half per cent; mineral, seven to ten per cent. (b) Bring to within a few degrees of boiling (if you do not wish to boil it), and repeat in three hours, after first cooling it down. Then cool again. (c) With liquor pancreaticus. Warm to 140° F.; let stand two or more hours; boil. (d) With lime water. (e) Curds are too large, and it contains too much proteid.

3. Give per cent of (a) oxygen, (b) nitrogen (in air). (c) What effect has burning lamp (or gas) on atmosphere? (d) Mention deleterious substances existing in sewer gas.

ANSWER.—(a) Twenty per cent by volume. (b) Eighty per cent by volume. (c) It consumes the oxygen and leaves carbon dioxide in its place. (d) Carbon monoxide, carbon dioxide, hydrogen sulphide, and others.

4. (a) How much water per day, in ounces, should be consumed by an average adult? (b) Mention most frequent pollution of water. (c) Give test for organic matter in same.

ANSWER.—(a) From thirty-two to forty-eight ounces. (b) Organic material from sewers, including typhoid germs. (c) Nessler's solution will give a brownish yellow tinge if minute quantity is present.

5. (a) Give general outline for disinfection and fumigation, (b) and comparative value of the following: (1) Formaldehyde, (2) sulphur, (3) chlorin.

ANSWER.—(a) If it be a room, fill all cracks and air connection with outside parts thoroughly with cotton. This includes chimney and the window joints, etc. From a formaldehyde generator fill the room through the keyhole with formaldehyde gas. Let stand twenty-four hours. Ventilate and scrub floor afterwards with one-twenty-thousandths corrosive sublimate. Clean well mechanically. (b) (1) Best and most practical, (2) good, if well used, but ordinarily too sparingly used, (3) chlorine is too dangerous, and too destructive. Is deadly, but disinfects.

SURGERY.

Answered by Dr. Frank K. Boland.

1. Give in detail the treatment of a recent open fracture of the tibia.

ANSWER.—Ascepticize thoroughly, and apply light dressing. Effect reduction by extension and counter-extension. Apply plaster cast from toes to middle of thigh, with fragments in apposition, and foot in straight line with leg. Cut window over the wound, surround window with rim of rubber tissue to protect cast, dress as often as necessary to keep clean. Keep patient in bed until wound is healed, after which he may get about on crutches. In five or six weeks cast is removed, and patient may put foot lightly to floor.

2. What are the symptoms of a subglenoid dislocation of the humerus?

ANSWER.—Pain, flattening of the shoulder, loss of prominence of the deltoid, elbow is away from trunk and backward, considerable lengthening of extremity, head of bone felt in axilla, rigidity of joint, and Dugas' sign (elbow can not touch side with hand on sound shounder). Reduction: Flexion of forearm, external rotation, lifting elbow forward, internal rotation, and lowering elbow. Dangers: Fracturing bone, injuring brachial plexus or axillary vessels.

3. Given a wound of the scalp, what investigation of the wound is necessary?

ANSWER.—Examine carefully for fractured skull, which may be complete or only through one table. Shave wide area. Use every aseptic precaution. Stop all bleeding. Suture lightly with silk-worm gut, draining, if necessary. Apply moist dressing.

4. What are the symptoms and what is the treatment of a gunshot wound in the kidney?

ANSWER.—Shock, and perhaps general symptoms of hemorrhage, which may prove fatal. Severe pain in loin, shooting into testicle. Tumor may form from hemorrhage or urine. Frequent and painful micturition or retention. Hematuria, unless urine leaks into peritoneum or surrounding tissues. Treatment: If wound is extraperitoneal, enlarge to permit drainage, arrest hemorrhage, ascepticize, and drain. Nephrectomy may be necessary. In intraperitoneal wound, perform laparotomy at once, and usually remove kidney.

5. Give and explain the symptoms of a strangulated inguinal hernia?

ANSWER.—Colicky pains and pains in the hernia, which is tender, without impulse on coughing, and irreducible. No gas or feces can pass, unless lumen of gut is not entirely constricted, or hernia is omental. Severe vomiting, which at first is reflex, and later is due to reversed peristalsis, and may become stercoraceous. Prostration, slight elevation of temperature, which, later, becomes subnormal. Pulse, small, irregular, fast; extremities cold; facial expression anxious. All symptoms augment until collapse occurs, or gangrene causes their temporary lull.

6. How would you differentiate between a fracture at the neck of the femur, without impaction, and a dislocation? Give Bryant's and Nelaton's lines for making the measurements.

ANSWER.—In fracture, limb is usually everted, and lies straight in the bed; in dislocation, the limb is adducted, rotated inward, and more or less flexed. In fracture, one may get crepitus, preternatural mobility is present, and passive movements in any direction are possible; in dislocation there is no crepitus, and extension, abduction, and outward rotation are impossible. In both cases the top of the great trochanter lies above Nelaton's line, a line drawn from the anterior superior spine of the ilium to the tuberosity of the ischium. Bryant's line: The distance between lines drawn through the two anterior superior spines, and the summits of the great trochanters is less on the affected side in both cases.

7. Detail the clinical symptoms and the surgical treatment of an empyema.

ANSWER.—Symptoms: Empyema usually follows some other disease or a serous pleurisy. There may be but little pain, cough and dyspnea, unless side is very full. Symptoms of septic infection are present, sweats and irregular fever. Physical signs of serous pleurisy are present; intercostal spaces are obliterated, there is a bulging, and on the right side the heart may be displaced; tactile fremitus abolished, dullness on percussion, and voice sounds lost. Aspiration proves nature of fluid. Surgical treatment: Remove inch or two of one or more ribs in axillary line, usually sixth or seventh, open pleura, and drain with rubber tube. Do not irrigate.

8. What are the clinical symptoms, and what is the surgical treatment of a purulent effusion into the knee joint?

ANSWER.—Symptoms: Swelling, redness, pain, loss of motion, and general symptoms of pus, usually; chill, sweats, elevation of pulse, and temperature, prostration. Treatment: Open and drain.

9. Describe the different avenues through which the urinary bladder, in the male, may be emptied surgically.

ANSWER.—(a) By suprapubic aspiration. (b) Suprapubic cystotomy. Incision just above pubes, avoiding peritoneum. (c) Perineal section, cutting through the median line down on sound as guide.

10. Give the differential diagnosis between an aneurism of the popliteal artery, and an abscess in the popliteal space.

ANSWER.—Pulsation of aneurism, expansion of abscess up and down. Pressure on artery above aneurism diminishes its size, below increases it; no effect on abscess. Bruit is heard in aneurism; abscess is red, and more tender to touch. History is important. Aneurism is of longer duration.

BACTERIOLOGY.

Answered by Dr. E. C. Thrash, Professor of Bacteriology, Pathology, etc., in the Atlanta School of Medicine.

1. (a) What is infection? (b) What is immunity? (c) Through what agencies may the body protect itself from consequences of infection?

ANSWER.—(a) Infection is an invasion into the tissues of pathogenic bacteria. (b) Immunity is that condition, either acquired or natural, in which the tissues are in a state to resist a specific form of bacterial invasion. (c) By Erlich's lateral chain method, by the opsonic method, by sudden changes taking place in the blood plasma, through which change phagocytosis is increased, and by the generation of antitoxins.

2. (a) Name the common pyogenic microorganisms, and describe (b) the microscopic appearance, and the behavior of the staphylococcus pyogenes aureus in osteomyelitis.

ANSWER.—(a) Staphylococcus pyogenes albus, aureus and citreus, streptococcus pyogenes, diplococcus intracellularis meningitides, and gonococcus. (b) Staphylococcus pyogenes aureus is a small, spherical-shaped organism, occurring singly, in pairs, or in clusters. They stain readily with methylene blue. In osteomyelitis they produce a primary infection, and enter the bone structures through the circulatory system, gaining entrance at some remote point, and after being deposited in these structures they set up an acute, purulent inflammation that results in a necrosis of the bone and surrounding tissues, which inflammation ultimately becomes chronic.

3. (a) What is meant by an antitoxin? (b) What is serum therapy? (c) Illustrate by two diseased conditions in which it is successfully employed.

ANSWER.—(a) An antitoxin is a substance that neutralizes toxine. (b) Serum therapy is the production of an excess of antitoxine in an animal's blood by inoculating the animal with toxin until it becomes tolerant to the poison. This antitoxine-laden serum is extracted from the blood of this animal and used as a therapeutic agent in the prevention and cure of disease. (c) Tetanus, diphtheria.

4. Describe in detail Widal's test in typhoid fever, and explain the principle on which it is based.

ANSWER.—A drop of blood is obtained from the patient suspected of having typhoid fever by puncturing the finger or lobe of the ear. This drop is collected upon a slide, another slide is laid over the drop, but not allowed to touch it, separating the two slides by a piece of match or toothpick. Allow to dry. Mix enough of this dry blood with sterile water, or bouillon, to produce a dark amber color. Then mix a small quantity of this solution with a twenty-four-hour growth of bouillon culture of typhoid bacilli grown in an incubator. Examine this by the hanging drop method. If reaction is positive, bacilli clump and become nonmotile. If negative, they continue motile, and there is no clumping. (b) It is based upon the principle that certain antitoxines are produced in the blood, which, when brought into contact with typhoid bacilli, weaken, paralyze, or kill them.

5. Give (a) the characters of the tetanus bacillus. (b) How does it induce its effects? (c) On what theory is tetanus antitoxin administered?

ANSWER.—(a) It is a slender, motile, club ended, anerobic, spore bearing, pathogenic, bacillus. (b) By producing toxines which poison the nerve centers. (c) That it will neutralize the toxines.—*State Board Journal of America.*

Texas Medical Law.

The Board of Homeopathic Medical Examiners of Texas will hold its last meeting at Fort Worth, Texas, July 4-5, 1907, to act on applications for license to practice in Texas. The law will change July 11, 1907. Applicants on State Board certificates from the more advanced States are entitled (Section 8, Paragraph 4, of present Texas law) to register without examination. This board has special arrangements for reciprocity with Missouri, Indiana, Iowa, Georgia, Virginia, and some others. Section 6 of the law forbids discrimination on account of school of practice.

Non-graduates may apply for license by actual examination. Board prefers not to examine those who have had less than two years in medical college, and none who have been examined and rejected by any Texas board since July 4, 1906, need apply to this board. All applications should be in by July 1.

H. B. STILES, M. D., *Secretary*,
Waco, Texas.

Editorial.

Are You Mentally Free?

Independence Day has again brought proud recollections of the glorious victories that brought liberty to our country. In the midst of all this boasting of our freedom, let us stop a moment to consider whether we are not still slaves to Mrs. Grundy—whether we are not held down by countless usages and precedents whose only recommendation is great age. How about our everyday life? Is it not burdened with many objectionable customs that could be easily abolished if we had the initiative? We tolerate unsightly and uncomfortable articles of wearing apparel simply because they are the fashion. The average man is perfectly content to accept a religion with a ready-made creed that he takes for granted is the whole truth; even though he may be unable to logically state his own belief, he is quick to condemn any faith with a different name from his own. The same is true of politics. The typical voter takes great pride in being "regular," and utterly ignores such trifles as the character of the candidate and the issues involved. To his narrow vision the acts of his own party are always above reproach, but he wears a pair of blue glasses when looking at what the opposition does. It is so easy to accept what is conventional as being just right, that errors and abuses seldom raise a word of protest. Any man will resent a sharp and unexpected personal wrong because of his animal selfishness, but our sense of justice has been so dulled that we are no longer concerned about the greater crimes that affect the community as a whole. Even though an injury only involves a neighbor at the moment, it is pretty sure to get around to ourselves in the end. The average man has come to wait the word of some self-appointed leader instead of thinking for himself, and coming to his own conclusions. When he does take time to

think, instead of showing originality his thoughts follow the same old ruts. It is ignorance and the habit of letting some one else do our own thinking that makes it possible for politicians in all the activities of life to gratify their ambitions by "working" the people. Is it too much to suggest that we investigate for ourselves before accepting as facts the statements of self-heralded authorities? What has been labeled "science," for instance, has often proved in after years to be only the false theory of a crank. Of course, it takes an effort to break away from intellectual slavery in the rush of present-day life, but surely freedom of thought is worth the price.

Danger in Substitutes.

A druggist in the *Pharmaceutical Era*, May 30, writes:

A physician who condemns secret remedies and criticises the sale and use of patent medicines can not claim to be consistent when he overlooks preparations the constituents of which he is perfectly familiar with, and prescribes the secret preparations of some manufacturing firm.

What this druggist is seeking, is to induce physicians to prescribe his and other druggists' imitations, made, presumably, after the formulæ laid down in that book of substitutes, the National Formulary, in place of the genuine proprietary preparations. In other words, when a physician has found out from his own experience, or has been convinced from the recorded experiences of other physicians, that a certain preparation is a useful and reliable remedy in certain conditions, he is not to prescribe this preparation of known value, but is to order an imitation of the same, made by the druggist. And he is urged to do this on the ground that the proprietary is a secret remedy, and the substitute is not. Now, there is little or no secrecy about the generally accepted proprietaries, the manufacturers, as a rule, telling practically all about their respective products which it is necessary to know in order to determine their therapeutic efficacy; and so, the argument as to secrecy can have no weight with the well-informed physician. But can he be so certain of the contents of a preparation made from a prescription, which may fall into some incompetent or dishonest druggist's hands to fill? Few doctors are willing to take the chance of making enemies of druggists by specifying the particular apothecary to which his prescriptions shall be carried, and so he can not tell whether the one who fills it is competent and honest, or not. And so, it seems to us, that he would prefer to order the original proprietary which is always uniform, and whose manufacturer must keep it up to the standard, instead of the imitation of uncertain composition and which has no reputation behind it. Perhaps the druggists can not be blamed for trying to get the doctors to prescribe their substitutes, for, probably, it means a few cents more in their pockets; but the doctor of common sense, who has regard for his own interests and for those of his patients, will be apt to see that he is not in business to help the druggist to increase his profits, and, hence, will go on prescribing the products whose worth has been proven, and upon which he can always depend for certainty of result and uniformity of action.

Substitution.

Readers are justified in suspecting the honesty of dealers that practise "substitution," or the gentle art of persuading a customer that he does not know what he wants, and that he ought to get an inferior article in order to give the dealer a bigger profit.

Substitution is objectionable from many points of view. When you ask for one thing, and the dealer tries to make you take another, he proves in the first place that he thinks you to be something of an idiot. If he thought you knew your own mind he would not try to make you take something that he manufactures, and that has no reputation, in place of the recognized first-class article that you ask for.

Everybody knows that an imitation, made of inferior ingredients, can be sold more cheaply than the real article which is bound to keep up its reputation, and which can not afford to risk a trade on which millions have been spent in promotion and manufacturing.

The use of bad alcohol in an external remedy, for instance, may cause a skin disease instead of curing it, whereas the real remedy, decently and honestly made, is of great value. The writer is acquainted with one retail merchant whose clerks always endeavor to sell to customers the imitation of a certain article. The owner of the store uses that article in his home every day and does not take any imitation. He knows better than anybody what the "just as good article" is made of.—*N. Y. Journal*, June 4, 1907.

The National Formulary Substitutes.

The druggists of Philadelphia have a custom of holding what they call "Pharmaceutical meetings." They gather at the Philadelphia College of Pharmacy, periodically, to discuss the various questions that arise in their business. At one of these meetings, held May 14, Mr. Ambrose Hunsberger read a paper on "Practical Results with National Formulary Preparations." He exhibited upwards of twenty of these substitutes, and cited some of the difficulties he had encountered in trying to make the same, and to get the physicians in his neighborhood to specify or to permit him to use them in place of the proprietaries they are intended to supplant.

Mr. D. J. Thomas, in discussing this paper, was inclined to question the advisability of pursuing this line of work, thinking *the rank and file of pharmacists are not prepared to meet the demand for making the U. S. P. and N. F. preparations.* He recounted some of the experiences that had come to his attention, which indicated that *pharmacists were generally not skillful enough to do this kind of work, and, in fact, that they have not, as a rule, kept themselves posted on the progress of pharmacy along the more practical lines.* He called attention to several of these formulas, that, when followed, *did not give satisfactory preparations.*

Mr. Lemberger told of his experience with cataplasm of kaolin, in which the *official article did not compare with the proprietary it was intended to imitate.*

Now, here is an instructive lesson to the doctors of this country, who really want to bring their patients to health, and who are not willing to be as "tenderly led by the nose, as asses are," by men, who, though occupying high official position in the profession, are yet no more truly solicitous for the welfare of the individual doctors than are the politicians interested in the public weal who so loudly proclaim their philanthropic and altruistic purposes. These druggists, in the privacy of their meetings, acknowledge what the BRIEF has a thousand times asserted, *that it is not possible for any man to analyze an organic mixture, and from such analysis to find out its ingredients, the exact quantities of each, and how these can be put together to duplicate the original product.*

The druggists of Philadelphia, and especially those who have received their training from that excellent institution, the Philadelphia College of Pharmacy, are the most skillful in the world. But here *they confess that the N. F. or U. S. P. formulas are untrustworthy, and that, therefore, it is impossible for them to be used to reproduce the standard proprietaries.* More than this, they make manifest, what is, however, a fact of common knowledge, that, even if the exact formulas and processes of manufacture of these proprietaries were given, that *the average pharmacist has not the requisite pharmaceutical skill to compound them in a satisfactory manner.*

These propositions are so elementary, they are so self-evident, that it is a cause for wonder that the movement for the substitution of the so-called N. F. preparation for medicines whose therapeutic values have been tested in thousands of cases, and whose effects are almost as definitely known as those of the standard drugs, can find either advocates or dupes.

The doctor who values his own reputation, who holds as sacred the trust his patients impose in him, is not going to be led astray by any pharmaceutical *ignis fatuus.* Nor will he be frightened by the bugaboo of ethics, which the politicians in his associations, for their own advancement and glory, are constantly setting in his pathway. No! He realizes that when a man devotes all his time to one or two preparations, that he is bound to develop a specialty in their manufac-

ture, and that even when he discloses his processes in full, that the little corner druggist, even if he is particularly desirous of doing so, has not the skill to reproduce these preparations. He realizes, also, that the manufacturer's reputation is at stake; that his business prosperity is dependent on his using the best of drugs in his preparations, and of maintaining a uniform standard of excellence for his products. And that, therefore, admitting he is not influenced by any higher consideration, the proprietor's own self-interest will compel him to supply preparations that are honest and reliable, and which, in every way, come up to the claims he makes for them. Doctor! "heed not the voice of the charmer, charm he ever so wisely." Do not use proprietaries because they *are* proprietaries, but use them or anything else that promises to secure the end you have in view—the restoration of your suffering patients to health. This is nothing more than practical, everyday common sense, and we do not believe any considerable number of intelligent, self-reliant physicians are going to risk their reputations and their patients' lives by using substitute preparations, whether made by his neighboring druggist or by the large pharmaceutical houses.

The Man of Independent Mind.

The late Senator John T. Morgan, of Alabama, was one of the few really broad-gauged statesmen of the present generation. He was, besides, a man of such integrity of character that not even envy, hate or party passion has ever imputed to him a dishonorable act or motive. But that which most distinguished him—the quality, above all others, that made him stand out conspicuous among his fellows—was *his independence* of mind. Though a Democrat of the straightest sect, he declined to attend the party's caucuses and steadfastly refused to be bound by their action. He did not *belong* to the party in the sense of subserviency to it, as the ordinary politician does. He considered, rather, that the party, in a measure, *belonged to him*—that it was but an instrument for carrying out his ideas of what constituted sound governmental principles and policies. If the leaders in the organization subordinated these principles to selfish ends or party expediency, he did not feel bound to follow them. He remained true to his own principles, regardless of what the organization might do.

It is, we think, unfortunate that there are not more men of his kind, not only in governmental employ but in every walk of life. Particularly, are such men needed in the medical profession at the present time, when there is a growing tendency for a few, who, though not especially skilled in the art of healing, yet, having the instinct of leadership, are trying to dominate the entire profession, to mould all doctors after their model, and to compel all to follow them into whatever devious paths they may drift, regardless of the fact that these would-be leaders have forgotten, in their desire to "boss," the only reason for the physician's existence, and that is to relieve suffering, to cure disease, to save lives. The independent physician cares nothing for organizations of any kind. They can not aid, and may hinder him, in the performance of his duty to himself and the public; and so he refuses to take his opinions and to mould his conduct at the behests of a few self-constituted physicians who are at the head of the associations, and who have mainly their own advancement and glory at heart.

Spring Medicines.

How often we hear the remark, "Doctor, do you not think I should take a spring medicine?" It is a fallacy, of course, to think that we need anything special in the spring, because the seasons have so changed that we can not tell when spring comes. Our calendar tells you the date, but when we consider that we have all the seasons in one week now, even to freezing weather, and the early vegetation all blighted, it sets us to thinking. The conscientious doctor will give remedies as per the indications, not according to the seasons. Perhaps this change of conditions is only temporary, but it may continue indefinitely, and put all the wiseacres to the test as to what is the cause.

The MEDICAL BRIEF has the largest paid circulation of any medical journal published anywhere.

[Written for the MEDICAL BRIEF.]

Pyorrhea Alveolaris and Oral Sepsis.

BY FREDERICK NORMAN, F. R. C. S., ENG.,
Surgeon to the Camberwell Dispensary.
London, England.

For some time past I have devoted attention to the subject of pyorrhea alveolaris, not so much for its own sake as from the circumstances that it is one of the factors in the production of oral sepsis, in which I am especially interested.

The condition known as pyorrhea alveolaris, or spongy gums, is also called Rigg's disease, and there is undoubtedly some mystery about this nomenclature, for I am not aware that any one of that name ever published any paper or article on the subject; at all events I can find no trace of it. I, of course, may be speaking in error, and I must admit that I have not access to every medical journal published in the United States. There seems to be but little doubt that the affection was named after Dr. J. M. Rigg, of Hartford, Conn. By some authorities it is stated that he was the first to describe the rational treatment of the disease. There is also a rumor that in 1867 he gave a demonstration, before the Connecticut Valley Dental Association, of certain instruments for removing salivary deposits from the teeth, and that the audience was so profoundly impressed by his ingenuity that they, as an especial mark of honor, conferred on him the paternity of this disease. But on this point I admit my ignorance, and I have no doubt that amongst the numerous readers of the MEDICAL BRIEF there are many fully conversant with the facts who are in a position to correct any mistake into which I may have fallen

I have no intention of describing all the varieties of this interesting disease, but speaking generally there is not only a spongy condition of the gums, but they recede, exposing a portion of the fangs of the teeth, which, no longer implanted firmly in their sockets, are loosened, and not uncommonly drop out. The inflammation involves the peridental membrane or periosteum of the fang, with the result that pockets of pus are formed, which extend along the roots, and result in destruction of the tissues of the gum and alveolus. It is said that this condition is due to the deposit of tartar from the saliva, but this explanation seems inadequate, and the disease is probably due to some specific organism, although as yet it has not been isolated.

The difficulty arises from the presence of many varieties of micro-organisms in the mouth. Most physicians regard it as a purely dental affection, and hand it over to their dental colleagues, who, however, usually receive it with no great en-

thusiasm. I cannot help thinking that it is something more than a purely local disease, for its persistence is attended with far-reaching effects.

Newland-Pedley, in his well known paper in the *Transactions of the Odontological Society*, describes the advanced stage of alveolar destruction in the following words: "The mucous membrane, especially that adjacent to the teeth, appears deeply congested and filled with venous blood, tumid and thickened, but not filling up the interstices of the teeth at their necks, and detached for some distance from the surface from the fangs. A thick fetid discharge may often be pressed up from between the teeth and the mucous membrane, which gives to the breath a very repulsive odor. This condition of things continuing, the alveolus becomes absorbed, whilst the fangs of the teeth become coated with a layer of thin, hard, greenish-brown tartar; ultimately, the disease progressing, the teeth one by one drop out. The alveolar margin is sometimes thickened in substance. The pain varies; it may be neuralgic from the first, but is not generally considerable until the periosteum is involved."

It has long been my conviction that the mouth is the hot-bed of many pathogenic organisms which perform a by no means unimportant rôle in the production of certain general disease of hitherto unexplained origin, but the source of which can be traced to the oral cavity. These pathogenic mouth bacteria are so numerous and so diverse in character that it is impossible to identify them by a simple microscopic examination of the saliva. Cultures on agar-agar are not satisfactory, for many of them will not grow on this medium, or are of such feeble vitality that they are soon ousted by the more proliferous saprophytes of the mouth. Gelatin is equally futile for the purposes of diagnosis, and inoculation into mice is the only reliable criterion. It is many years since Pasteur discovered in the human saliva a pathogenic micro-organism in the form of the figure 8, and since then Miller of Berlin, Fränkel, Gaglio, and di Mattei, Banti, Foâ, and many others, have furnished contributions dealing with the toxic properties of the saliva.

When a few drops of salivary secretion are injected into the abdominal cavity of a mouse, death ensues in a few hours, or it may be in a few days, from acute peritonitis or blood poisoning or both. Injections with the blood or peritoneal exudations of these animals produce the same results as injections with the original saliva. Of salivary organisms cultivated on artificial media, more than a score have been isolated and identified. Amongst the most important are Fränkel's diplococcus of pneumonia (possibly identical with the organism originally described by Pasteur), the micrococcus pneumoniæ of Friedländer, and the bacillus bucallis muciferens and various varieties of bacilli sputum—septicemia. In addition to actinomyces and saccharomyes albicans (thrush fungus), the bacillus tussi convulsivæ and the bacillus bronchitidis putridæ are not infrequently detected.

Goadby, of the National Dental Hospital, London, has recently published some excellent work on the subject, and the bacteriological methods he employed were as follows: Cover-slip films were made in some cases from the gum margin, and in others from the interdental spaces and pockets after irrigation with boiled water. Antiseptics were discontinued, owing to their inhibitive effect upon the cultures. The films made were stained by one of the aniline dyes; in the first portion of the work generally aniline gentian violet, but latterly Leishman's modification of Romanowsky was found to give better results. Agar streaks were made at the same time, plated by the smear method, and the colonies picked off at the end of from two to five days, and examined by the usual methods. In a number of the cases, films were also stained by Ziehl-Neelson, and by Gram's method. During the earlier part of the work, only a few of the isolated organisms were tested on ordinary media, namely, those that appeared to occur with the greatest regularity. Very little evidence was obtained of any one organism occurring with sufficient regularity to suggest its casual relationship with the disease under investigation.

In order to control the bacteriological finding as far as possible, the bacteria occurring in other conditions of the

mouth were also investigated—namely, gingivitis, ulcerative stomatitis, simple ulceration of the gums, the gums in scarlet fever and normal gums. The chief fact brought out is that a very much larger variety of species is found in the gums in ulcerative conditions, and that the bacteria found on the cover-slips directly in gingivitis and ulcerative stomatitis show a very curious similarity to those found in pyorrhea. The number of cases in which spirochætæ, spirilla, and comma-shaped bacilli were found is of interest. In most diseased conditions of the mouth, spirilla and spirochætæ appear in large quantities. They, however, as rapidly disappear upon the use of local remedies, notwithstanding the fact that the disease itself does not.

In a subsequent series of experiments the results were checked by observations on the opsonic index, and these yielded fairly satisfactory results. Inoculation experiments were also resorted to, and various animals were inoculated with pus obtained from cases of alveolar pyorrhea. Some of them died, but many recovered, some exhibited local lesions, others general infection, but without giving any regular or uniform results. This is in accordance with the observations of previous observers.

Respecting the etiology of the diseases we know curiously little. It frequently occurs in the course of chronic dysentery, influenza, and enteric fever, and has been met with in diabetes mellitus. In some cases I have traced it with approximate certainty to the use of impure or infected milk. It certainly occurs frequently in those who wear ill-fitting dentures. Some of the worst cases I have seen have been in men who are inveterate smokers, the teeth being so loose as to be useless for the purpose of mastication. It is rare in children, but I have met with it in connection with cancrum oris.

Its effects are far reaching, and the constant drain of septic material into the stomach must prove prejudicial to health. I have known it produce anemia, and in many of my cases the erythrocytes have been down to three million five hundred thousand per C. M. M., with a hemoglobin value of from sixty to seventy per cent. I can not confirm Hunter's observation that it may produce pernicious anemia, but the suggestion seems not unlikely. I have certainly known it responsible for a persistent chronic diarrhea. Murrell states that he has traced a certain form of arthritis to this cause, and his observations have been confirmed by other writers. For example, Prof. Howard Marsh has pointed out the connection of septic conditions of the gums with certain articular affections, especially rheumatoid arthritis.

He says: "The part played by the tonsils in the lymphatic tissues of the pharynx in harboring agents by which the joints may be infected has only recently been fully appreciated."

The primary septic focus may be in connection with a necrosed tooth. He mentions two cases in which after carious teeth were cut down level with the gum, and a new crown was applied, the patient became subject to an acute osteo-arthritis involving several of the larger joints, and those also of the hands. The fangs were removed, and pus was found in the sockets. In both these cases the joint affection was arrested. In the case of a lad who was anemic, and had enlargement and stiffness of the finger joints, and swelling and stiffness of both ankles and one elbow, the site of the infective focus was indicated by the discharge of a small quantity of pus which had been going on intermittently from a pin-hole opening in the gum opposite the bicuspid teeth of the lower jaw. Here, again, operative treatment proved successful, and the patient was completely restored to health.

The treatment of the disease is, to a great extent, surgical, but the whole subject must be regarded from a more extended point of view, and as a phase or manifestation of oral sepsis.

The necessity for the adoption of antiseptic methods in all surgical operations is fully admitted, and is scrupulously enforced in every region of the body with the solitary exception of the mouth and throat. No one seems to think of antiseptics in connection with tonsillotomy and uvulotomy, and that in spite of the fact, as has been shown, that the mouth is a receptacle for germs of all kinds, some benign, and some pathogenic. It is true that in operations for the removal of

the tongue for cancer, antiseptic precautions are observed, possibly from the fear of septic pneumonia, and it is safe to say that the mortality from this complication decreases in direct proportion to the strictness with which these measures are carried out. In these cases, the patient is put through a preliminary course of dental treatment, all necrosed stumps being extracted, and all decayed teeth carefully stopped. But still the main proposition stands, and in the majority of operations in the region of the mouth and throat equal care is not observed. This carelessness is not readily capable of explanation, unless on the grounds that the methods by which oral sepsis can be insured are not fully appreciated. The demand for the adoption by dental surgeons of the antiseptic measures observed in general surgery is becoming imperative..

The point we have to consider is (1) what steps can be taken to prevent the growth of bacilli, pathogenic and non-pathogenic, in the mouth, and to limit, as far as possible, the action of micro-organisms on the teeth and other organs of the mouth, and (2) to keep in check those far more serious diseases which so frequently result from want of attention to the mouth. There are many diseases of the mouth which readily take on a septic character, and although the list of mouth-washes and gargles is comprehensive, there are none free from serious disadvantages. Carbolic acid and members of the phenol group are not only toxic in action, but exert a deleterious effect on the mucous membrane of the mouth, producing in the epithelium a carnification which is undoubtedly a step on the road to the pre-cancerous stage. It is important to avoid injuring in any way the protoplasmic cells, which by their function and activity resist the onset of malignant disease.

As I have pointed out in previous communications on this subject, it has been my practice for some years to instruct the patient to paint the gums daily with a mixture of equal parts of tincture of aconite and tincture of iodine. For occasional use I employ equal parts of the tincture of iodine and the liquor iodi fortis, but this must be used with caution. I have also used menthol with advantage, and tablets containing menthol, cocaine and rhatany. Formic aldehyde is probably the best antiseptic for local use, and the chemical combination of formic aldehyde and menthol known as Formamint, has proved satisfactory in my hands. The point to remember is that whatever application is used, it must be kept up without intermission for weeks or even months. Lozenges have many advantages over mouth washes, for they can be slowly sucked, both day and night.

Although I am a strong advocate for what may be called local antiseptic measures, in these cases it is not to the exclusion of purely surgical treatment. All I urge is that an effort should be made to restore the gums and their adjacent tissues to a normal and healthy condition before resorting to more drastic measures. I am in favor of early extraction when the teeth are loose in their sockets, although I admit that loss of teeth means an artificial set, which may not always be comfortable, and are at the best difficult to keep clean. They afford a lurking place for micro-organism of all kinds, and are opposed to all principles of oral asepsis. I advocate conservative measures, as a general rule, but if surgical skill must be resorted to, let it be thorough and sweeping. I am, in the main, in accord with the general principles of treatment advocated by Goadby, who says:

"Local applications, curetting, electrolysis, and many other methods have been recommended for treating the local disease, all of them being directed towards removal of local agglomerations of bacteria calculus and débris, and the enjoinment of constant care on the part of the patient after such treatment has often cut short the disease in the earlier, and much ameliorated it even in the later stages, but as long as lowered resistance to the infective organisms remains, so does the disease progress. These facts and the consideration of the bacteriology of the disease, point to the urgent want of some method by which the general as well as the local infection may be attacked. It is impossible where any marked erosion or solution of the alveolar process has taken place to cause regeneration of the bony crypts of the teeth, or a re-estab-

lishment of the periosteum upon the denuded fangs.

Where a considerable amount of bone infection has occurred, but without the loss of the thin margins of the sockets, and where the peridental membrane is still intact, more may be done. In the first place it is useless to endeavor to preserve the gum and other tissues above the level of the bottom of the pocket, for if the pocket be allowed to remain, it only becomes the site of fresh infection, and the recommencement of the disease in tissues already weakened by the diseased process. On broad general lines, the alveolar pockets should be eradicated, a process that is best performed by means of the electro-cautery, only a few, at the most three, teeth being treated at a single sitting. The removal of deposits of calculus around the necks of the teeth should also be performed in the usual manner.

I have observed that thorough curetting of even two or three sockets of affected teeth is generally attended by an increase of the constitutional symptoms already present. Delayed healing, especially in the case of the wounds caused by the cautery, is common, and is frequently seen where multiple extraction is performed in cases of general pyorrhea, and I think it is inadvisable to remove more than two or three of the teeth at a single sitting or undertake extensive cauterization without previously raising the general resistance of the patient to the infecting organisms."

In a paper read before the Royal Medical-Chirurgical Society, of London, in 1900, Mr. Rickman J. Godley advocated the plan of, after removing the tartar, syringing the pockets methodically with peroxide of hydrogen, at first twenty volumes, and then ten volumes. Other applications which have been recommended are sulphate of iron, sulphate of copper, and other astringents on small swabs of wool pushed down into the pockets. I can not say that these methods have yielded any very startlingly good results in my hands. The plan I usually adopt is as follows:

1. In quite early cases, as soon, that is, as the edge of the gums assumes a purple color, and is receding from the fang of the tooth, whilst a gummy exudation can be squeezed from beneath, I find that thorough applications of astringents and antiseptics usually suffice.

2. In moderately severe cases, where the disease has spread as far as the apex of the fang, the implicated tooth or teeth should be removed, so as to expose the loculi containing septic matter. Peroxide of hydrogen is then applied, both to deodorize and disinfect, a strip of antiseptic gauze being used as a dressing for the cavity. This application should be made twice a day.

3. In the most severe cases the lowered vitality and diminished resistive power of the system due to the absorption of toxic matter, both inhaled and swallowed, combined with the local action of pyogenic and saprophytic organisms which find abundant pabulum for the formation of intensely irritating chemical bodies, produce in the bone around the loculi a condition of rarefying osteitis. Here the most radical treatment is absolutely necessary if a rapid cure is to be effected. With a sharp spoon, all soft material must be thoroughly scraped away until hard bone is felt, when pure carbolic acid should be applied, and the cavity packed fairly firmly, the dressing being changed every four hours during the day. By the adoption of these methods, I usually succeed in effecting a complete cure, and without subjecting the patient to much inconvenience.

[Written for the MEDICAL BRIEF.]

A Contribution to the Pharmacological Actions and Therapeutical Uses of Manganese.

BY C. D. F. PHILLIPS, M. D., F. R. C. S. (EDIN.), F. R. S. (EDIN.), LL. D. (ABER.), LL. D. (EDIN.), LL. D. (GLASG.).

Late Lecturer on Materia Medica, Pharmacology and Therapeutics, Westminster Hospital, London, and Examiner in the Universities of Edinburgh, Glasgow and Aberdeen. London, England.

There is no doubt that in the domain of *materia medica*, manganese occupies a somewhat anomalous position. The therapeutical value of its salts is well established, but its pharmacological actions have not yet been worked out with that completeness of detail which has been observed in the case of other drugs such

as aconitine, digitalin and strychnine. The deep-rooted belief that manganese is in some way related to iron and that it is useful in anemia may have something to do with the false position assigned to this useful remedy. A reputation of this kind is eradicated with difficulty, although numerous observers have shown that manganese is of no value in the treatment of either common anemia or the pernicious variety.

The preparation of manganese commonly employed is the permanganate of potassium, although this can not be regarded as typically representing the manganese action. The same may be said of the permanganate of sodium and the permanganate of calcium. The binoxide of manganese is insoluble in water, but dissolves readily in hydrochloric acid, so that it is therapeutically active. The citrate is soluble and is a double salt with sodium citrate. There are various combinations of the citrate of manganese with iron, quinine, strychnine and other bases, but these are outside the scope of the present investigation, which is largely pharmacological. With respect to the permanganate in which the manganese occurs in the acidic radical there is reason to think that it is decomposed in the stomach, forming a salt of manganese, so that its further action may be attributable to the manganese-ions. Its utility is due to its capacity for parting with oxygen to albumin or other organic matter. It is used as a disinfectant and deodorant, but its power in this direction is limited, for when it yields up its oxygen it becomes inert.

The literature of manganese is tolerably extensive, although it must be confessed that the conclusions arrived at are not always reliable or at all events conclusive. Such discrepancies are not unusual in the case of salts presenting a complex chemical composition.

Sir William Turner, of Edinburgh, found evidences of manganse in the urine of a diabetic patient who had taken potassium permanganate for three weeks, showing that that salt was absorbed and eliminated by the kidneys. These observations were made more than forty years ago. Traces have been found in the urine of man and more than traces in the urine of herbivora; these are derived from vegetable food, hence there must be some absorption and therapeutical effects confirm this.

The presence of manganese as an essential element of the corpuscles has been relied upon as a guide to its action, but it seems to be rather an accidental than a normal constituent of the blood. Wurzer first announced its presence, and Millon, Hannon and Burin-Dubuisson corroborated this, while Melsens, Bonnewyn and others could find no manganese on repeated analysis. Melsens operated on seven kilogrammes of blood from twenty-one different persons. Glènard analyzed in various ways blood from forty subjects of varying ages, and found the metal in one case only. He concluded "that manganese is not an essential element of human blood; it may be found accidentally, but only in minute amount; it does not enter by the lungs or skin, as proved in the case of miners." Riche detected minute quantities in the blood of bullocks and a trace in human blood.

According to Laschkewitz, the organic salts of manganese in moderate doses (subcutaneously) slow the pulse and the heart-action, and cause lowering of the blood-pressure and paralysis of muscles and nerves; after death from manganese poisoning the heart is found dilated and does not respond to electrical stimulation. This may be the case in laboratory experiments, but in a case of acute poisoning (thirty-five minutes) from a large dose of permanganate taken in beer the heart was arrested in systole. Professor Kobert finds that the intravenous injection of manganese salts first transiently stimulates the vaso-motor center, then paralyzes it; later the heart itself is depressed and finally paralyzed; the cardiac nervous centers suffer first and later the muscle.

Certain nervous phenomena are determined by manganese salts. Toxic doses cause death with convulsions and one-half to one gramme injected into the veins of rabbits or dogs produces cramp and death from heart-palsy, or else faintness and weakness and slower death with fatty degeneration. The pupils are dilated; the temperature is unaffected. Rabuteau injected a little more than one gramme into a vein of a dog, and at first there were no symptoms, but on the fol-

lowing day tetanic convulsions set in with trismus and opisthotonos, and death followed shortly; the white substance of the spinal cord was shrunken, the grey matter congested. Kobert states that rabbits after large doses subcutaneously die in epileptiform convulsions; after non-lethal doses they suffer from diarrhea, loss of appetite, and great depression of the function of the spinal cord, the transverse conducting power being destroyed, though the longitudinal conduction remains intact. In dogs excessive vomiting and great nervous depression are seen after hypodermic injection; there are no convulsions, but jaundice and renal inflammation are striking symptoms always present. It must be remembered that rabbits can not vomit, hence the difference in symptoms.

Large doses given for a long period induce effects analogous to those of zinc—progressive wasting and feebleness, a staggering gait and paraplegia. Kobert states that chronic poisoning can only be induced if the salt is administered by subcutaneous or intravenous injection. Cases of chronic poisoning observed in man have been reported by Couper in workers in manganese. The symptoms were muscular wasting and paralysis, which may have been due to other metallic admixtures.

The sulphate has been credited with the power of stimulating the secretion of bile since the observations of C. G. Gmelin, who found in animals poisoned by large doses inflammation of the stomach and intestines, and "so large an amount of bile poured out that the whole tract was colored like yellow wax." He reported a less degree of the same effect in man, and Ure found that sixty to one hundred and twenty grains acted as a cholagogue purgative. Goolden took various doses from one up to thirty grains before vomiting occurred, but states that as a rule ten to twenty grains will cause nausea and purging with a copious secretion of bile. Professor Rutherford, however, failed to corroborate this experience, at least in animals, for after giving sixty grains to a dog, the biliary secretion was at once lessened, and severe diarrhea occurred. After death the mucous membrane of the small intestine was found pulpy, "as if the epithelium had been dissolved by caustic." In another dog a dose of twenty grains caused lessening of bile, although benzoate of sodium given afterwards stimulated its secretion. Rutherford concludes that the drug is a powerful intestinal, but not an hepatic stimulant, acting very like sulphate of magnesium, so that this particular salt can hardly be regarded as presenting the action of the manganese-ions.

The following observations may serve to throw some light on moot points connected with the pharmacology of manganese:

The close chemical alliance of manganese to iron has led many investigators to administer it to the animal economy with the view of ascertaining if it may not be possible to replace the latter metal in the blood by the former. But the results obtained are more or less contradictory, and it is therefore desirable, not only from the mere theoretical, but also from a practical standpoint, to establish the fact whether, when every imaginable consumption of iron is avoided, the manganese given in an iron-free diet to a living animal, could be made to act as a substitute for it. Since the artificial producing a manganese hemaglobin is impossible in the present state of chemical knowledge, a preliminary research had to be made with the view of selecting from the different groups of manganese compounds one which would have a neutral effect on the entire organism except upon the blood itself.* The experiments performed were the following:

THE EFFECT UPON THE COAGULATION OF EGG ALBUMIN OF MANGANESE PREPARATIONS.

PREPARATION.	AT 15°C.	AT 100°C.
Permanganate of Potassium	No precipitate	No precipitate
of Sodium	No precipitate	No precipitate
of Calcium	No precipitate	No precipitate
of Barium	Abundant.	Coagulation.
of Zinc	Flocculent.	Coagulation.
of Silver	Precipitate.	Coagulation.
Manganese:		
Chloride	No precipitate	Coagulation.
Bromide	No precipitate	Coagulation.
Iodide	No precipitate	Coagulation.
Acetate	No precipitate	Coagulation.
Citrate	No precipitate	Coagulation.
Lactate	Trace of precipitate	Coagulation.

* Turner (1861), Vulpian (1881), Lacerda (1882), worked out permanganate of potash and proved its action due to its oxidizing power. Gmelin (1824), worked fully the sulphate of manganese. Couper (1837), worked out manganic acid (MnO). Laschkowitz (1866) worked out the action of the lactate and citrate upon frogs, rabbits and dogs. Hoppe-Seyler (1858), worked out fully the sulphate. Wibmer (1831) found the carbonate of manganese perfectly inert.

THE PRECIPITATION OF PROTEIDS BY MANGANESE CHLORIDE, BROMIDE AND IODIDE.

None of these substances were found to precipitate egg albumin, propeptone.

Fibrin is dissolved only to a very small extent by saturated solutions of manganese chloride.

THE ACTION UPON THE BLOOD OF SOME OF THE MANGANESE COMPOUNDS.

The effect on the red blood corpuscles of man:

5% Watery Solution of	Reaction.	Observations Under the Microscope.
Permanganate of Potassium.	Strongly acid.	First, crenates corpuscles slightly and some plasma exudes. No formation of rouleaux. Secondly, discs become brown spheres.
of Zinc.....	Acid.	The discs become oval. A bulb can be seen at one end of a single disc.
Manganese: Chloride.....	Feebly acid.	Retain their shape, but after twenty-four hours become crenated.
Sulphate	Feebly acid.	Discs at once become shrunken, and like stramonium nuts. After twenty-four hours discs appear normal again.
Citrate.....	Neutral.	Decolorizes the discs, the stroma may be seen. No crenation.
Lactate	Acid.	No alterations observed.

NOTE—The acidity was tested by litmus paper.

THE ACTION ON THE SPECTROSCOPICAL APPEARANCE OF THE BLOOD OF SOME OF THE MANGANESE COMPOUNDS.

The blood of frogs was used. The permanganates of potassium, sodium, calcium, barium, zinc and silver turn the spectrum of oxyhemoglobin into that of methemoglobin, which was afterwards confirmed by changing it back again into hemoglobin by the addition of ammonium sulphide, or better still, by Stokes' reagent. Under similar circumstances the permanganate of potassium exerts the strongest action, so that two drops of a five per cent solution will produce the characteristic line of methemoglobin in blood diluted forty times, provided that about fifteen c.c. be taken, whereas permanganate of zinc requires double that amount to produce it, although on the left side of Frauenhofer's Line D. a shadow is very quickly perceptible.

The manganese salts of the organic acids, acetic, citric and lactic, leave the oxyhemoglobin for a long time unaltered: upon the first addition the bromide and chloride do not seem to produce any pronounced change, but if strong concentrations of oxyhemoglobin were employed there could be demonstrated a change going on in the color of the solution, which alteration could also be recognized by the spectroscopical appearance.

For example, the following experiment may be described:

Take the blood of a frog, shake it up well with air, divide it into two parts in two test tubes of the same caliber.

The results are tabulated below:

A.	B.
1st Action— Dilute with water.	1st Action— Dilute with saturated watery solution of manganese chloride (Columbers).
Observation— No alteration in color, only in depth.	Observation— Distinct alteration in color, the blood assuming a brighter tint.
Spectroscopically— All absorbed except orange and red rays, which are quite bright.	Spectroscopically— Absorption of violet end to D. of red to B. half shadow to C.
2d Action— Dilute till green rays between F ½b is visible.	2d Action— Dilute of manganese chloride gives no appearance of same part of green. Absorption of red rays scarcely weakened.
3d Action— Dilute till oxyhemoglobin lines are distinctly visible.	3d Action— Dilute with same amount of $Mn.Cl_2$ absorption of red rays as above half shadow between F and G.

The two test tubes closed and put aside and after months one appears to contain hemoglobin and the other acid hematin.

Blood.—In regard to the action of manganese compounds on the blood and its constituents, it may be stated that *the permanganate compounds*, from their oxidizing power, dissolve the whole mass of *the blood* into a clear brown solution, and at the same time they distinctly arrest the coagulation of the blood. It must always be remembered that permanganate salts act in virtue of their being so highly oxidized, and not owing to the manganese they contain.

Fibrin.—If fibrin be taken, which has been either preserved by hardening in alcohol or freshly prepared, and exposed

to a solution of permanganate of potassium, it will be found readily to be dissolved by the permanganate of potassium, yielding a brown solution. From this solution it may be precipitated by the addition of sodium chloride, the solution formerly brown becoming quite colorless or a little flesh pink. A similar reaction may be effected by means of sodium-bicarbonate in place of the chloride.

The manganese acetate, citrate, and lactate, hinder the coagulation of blood, and similarly manganese bromide and chloride arrest the clotting of it also.

Blood.—In regard to the manganese chloride a further observation was conducted. An equal amount of frog's blood was placed in two dishes; one was treated with distilled water, the other with manganese chloride (five per cent of aqueous solution).

After one hour the aqueous solution of the blood consisted of one large clot; the manganese chloride preparation in the same length of time, however, was still liquid, the red plasma mixing in beams with the serum and manganese chloride if the dish was turned to one side, *i. e.*, the corpuscles had been allowed to gravitate to the bottom of vessel.

After twelve hours the same condition was maintained, both preparations still being red in color, but after twelve hours more the manganese compound became brown, owing to the formation of acid hematin.

Fibrin.—Fibrin becomes, to a very small amount, dissolved by saturated solutions of manganese chloride.

If the filtered solution of fibrin in permanganate of potassium is left to stand two days, then a brown flocculent precipitate is thrown down.

If this solution now is subjected to heat and treated with sodium chloride there is neither an increase in the quantity of precipitate nor the production of a violet color in the solution, as might be expected and would be due to the formation of permanganic acid or to manganese sulphide, which would be of a flesh pink color.

Blood Serum.—In respect of the *proteids of the serum of the blood*, the scheme (table 1) for egg albumin holds equally good for them also. Manganese chloride does not precipitate serum albumin, even if the solution be saturated with it.

The effect upon the capillaries of the frog.

The action of *permanganate of potassium*, K. Mn. O_4, upon the *capillaries*.

2.5 c.c. of a saturated solution of permanganate of potassium was added to 22.5 c.c. of a 0.6 per cent solution of chloride of sodium. The vena hypogastrica of a large frog was prepared, and ten minims of the above solution were injected.

The frog having been made reflexless by destroying the nervous communication between the Occiput and Atlas vertebra, the circulation, which was observed by the microscope in the web of the frog's foot, was seen to stop for one moment, but it commenced to go on again almost immediately. After a quarter of an hour capillaries *formerly not seen* could be observed by the *appearance of a red color in them.* In about three-quarters of an hour the circulation was stopped in one of the larger vessels, though in the smaller ones it still went on; and the blood corpuscles continued to present their normal appearance.

The stoppage of circulation having spread, *the heart was exposed, but still found beating.*

This experiment shows the difference between the action on the heart of manganese chloride and permanganate of potassium.

EXPERIMENTS CONCERNING THE DEPOSITION OF DISSOLVED FIBRIN IN PERMANGANATE OF POTASSIUM IN THE BODY.

Fresh purified fibrin was dissolved in permanganate of potassium, to complete saturation, and the solution filtered, and in the filtrate the presence of the fibrin, or that of the body which replaces it, was shown by means of sodium chloride test.

Under the skin of the neck of a medium-sized guinea pig ten c.c. of this filtrate were injected. Protracted pains were observed after the injection, lasting for about two hours; after nine days the animal was found dead, though in the meantime no symptoms had been observed which could be ascribed to the injection.

Post-Mortem Examination.—General appearance of the parts at site of injection

was perfectly normal; subcutaneous connective tissue of the neck was of a brown color, the point of the wound light red, and around it a small deposit adherent to the skin had formed. This deposit was of a hard consistency, was perfectly white, and showed, when cut, a fibrillar structure.

The brown red connective tissue, with some fat, was then cut out and placed in a vessel and treated with distilled water. This watery extract showed with the spectroscope oxyhemoglobin, but no methemoglobin, and the absorption bands of the permanganate of potassium could *not* be detected in it. There was *no* manganese reaction with ammonium sulphide, nor by fusing with saltpetre and soda.

Another guinea pig was similarly treated. It was killed after two days and during that time lost one-twentieth of its weight. The general results were the same as in the foregoing instance.

EXPERIMENTS WITH REGARD TO THE ELIMINATION OF MANGANESE FROM THE BLOOD.

A rabbit weighing five pounds was injected subcutaneously with two c.c. of five per cent solution of manganese chloride solution. During the following twenty minutes no effect was observed; during the next four or five hours three more injections were given of the same solution, making a quantity of fifteen c.c.

The pulse was counted fifteen minutes after each injection—the animal being at the time under no narcotic—and a diminution in rapidity was observed, viz.: two hundred, one hundred and sixty, one hundred and four per minute respectively. Three hours afterwards no abnormal symptoms could be observed, but sixteen hours after the first injection it was found dead.

Post-Mortem Examination.—Rigor mortis was not pronounced one hour after death. Much injection of the vessels was observed around the puncture produced by the cannula of injecting needle. The blood was brown and clotted. The kidneys hyperemic. The blood in the vena cava was fluid, ecchymoses were found on the surface of the lungs. Chemical examination showed manganese present in the kidney, urine, brain, and especially in the liver, but none in the blood.

EXPERIMENTS CONCERNING THE ACTION OF MANGANESE BROMIDE A CHLORIDE ON FROGS.

Frogs.—The effect of bromide chloride of manganese when exh subcutaneously.

(*a*) A frog weighing twenty grammes was injected with two c.c. aqueous solution of manganese br under the skin of the back. The fro viously very lively, showed the first toms of poisoning in ninety seconds duction of the four limbs, and co inactivity. Thirty seconds later e drooped and respiration was slowe deeper, and four minutes after the tion no respiratory movement co observed. The thorax was then o and the heart had ceased to beat, a of a deep venous color; it respon pinching by single contractions on

At site of injection there was n venous hyperemia. The blood in t sels appeared black, only in certain brown, the arteries of the skin were distended.

(*b*) A frog weighing thir grammes was similarly injected wi c.c. of an aqueous solution of man chloride.

There was no difference recogn between the result of this treatmen that of *a*, either in a general or par sense.

Rabbits.—The effects of man chloride when introduced by the m

The hydrochloric acid in the st does not form a new compound. A weighing five pounds received five five per cent solution of manganese ide as an injection into the stomach effect being observed after ten m the dose was repeated. During th three days the rabbit appeared to excellent condition. On the third d other four c.c. of the same solution thrown into the stomach. It was dead the following morning.

Post-Mortem Examination—No mal anatomical appearances were The lungs were full of air. The re of the liquid in the stomach was Urine contained albumin and also the green violet rings with nitric (Gmelin's test for bile pigments.)

The contents of the stomach gave a similar reaction when filtered and treated with nitric acid.

In two other instances in which manganese chloride was similarly introduced into the stomach, the urine of the animals after death gave the reactions of albumin and bile, no manganese could be detected in the blood. The mucous membrane of the stomach in both cases was partially necrotic.

Gmelin has shown that sulphate of manganese in large doses in dogs and rabbits, given either by the stomach or subcutaneously, causes general icterus, and bile may be detected in the urine. (Versuchen über die Workengen des Baryts, u. s. w., auf dem thierischen organismus. (Tubingen, 1824.)

He also specially alludes to the gastro-enteritis and to the peculiar form of nephritis, which partakes of a parenchymatous or interstitial character.

INJECTION OF MANGANESE CHLORIDE INTO A DOG BY THE MOUTH—GASTRO-ENTERITIS.

Male dog weighing fourteen pounds received a subcutaneous injection of ten c.c. of seven per cent solution of chloride hydrate, and ether was administered.

When narcosis was established, an injection of five grammes of manganese chloride in twenty c.c. of water was given by means of a catheter into the stomach, and narcosis stopped. The dog immediately tried to walk about, but had no coordination of his limbs. Four minutes after the injections he vomited matter containing an abundance of manganese. In twenty minutes he vomited for a second time, and again in two minutes after that. Manganese could readily be detected in each instance. He then fell asleep. The following morning he was greatly depressed, refused food, and ultimately died thirty-six hours after the administration of the drug.

Post-Mortem Examination.—The stomach contained only blood and mucus. The surface of the viscera was pale, and hemorrhages were discovered throughout the whole of the mucous lining of the intestinal tract, some being the size of a shilling, others smaller. The intestine was filled with a dark colored fluid, consisting of mucus and blood.

Manganese could not be detected in the urine nor in the blood of the limbs, but it was found in the brain.

EXPERIMENT TO ESTABLISH WHAT DOSE OF MANGANESE CHLORIDE A DOG COULD BEAR.

A dog weighing fourteen pounds was injected subcutaneously with ten c.c. of ten per cent solution of chloral hydrate, and twenty minutes later ether and chloroform were given. Respiration sixty-nine and pulse two hundred per minute.

After the reflexes were abolished 0.25 grammes of manganese chloride was injected under the skin, the fatty tissue being avoided. One minute after the injection, respiration forty and pulse one hundred and eighty per minute.

During the next ten minutes no further symptoms developed and the chloroform was stopped, and in eight minutes more the animal walked about without any symptoms which could not be directly referred to the chloroform.

The animal was somewhat depressed and sleepy during the following week, but after that completely recovered.

Six weeks after the injection it was killed, and the *post-mortem* examination revealed nothing abnormal. No gastro-enteritis could be recognized.

The anesthetic to a certain extent vitiates this experiment.

EXPERIMENTS UPON THE ACTION OF MANGANESE CHLORIDE ON THE HEART OF THE FROG.

A frog's heart was excised, and a drop of five per cent solution of manganese chloride placed upon it. Instantly, contraction ceased and it was not possible to excite even a single contraction again.

When one-tenth per cent solution was employed the heart's contraction ceased, and could not again be made to continue to contract, though single contractions could be produced on mechanical initiation.

ANTAGONISM BETWEEN MANGANESE CHLORIDE AND PERMANGANATE OF POTASSIUM.

If a solution of manganese chloride of a strength sufficiently weak for the animal to bear be injected under the skin of a frog, and under similar circumstances

permanganate of potassium be employed, the following is the result observed:

ACTION.	$Mn\ Cl_2$	$K.\ Mn\ O_4$
On the heart	Destructive.	Indifferent or Increased.
Excitability of reflex action	Diminished.	Increased.
Blood	Reduction .. (Hematin..)	Oxydisis.

EXPERIMENTS CONCERNING THE SUPPOSED ASTRINGENT POWER OF MANGANESE CHLORIDE.

A dog suffering from a severe conjunctivitis was experimented on.

The palpable conjunctiva was painted every other day with five per cent solution of manganese chloride.

No astringent effect was noticed locally, even after five days, but some brown spots were visible in the region of the insertion of the inferior oblique muscle. The pupils were dilated.

On the sixth day the animal was killed.

Post-Mortem Examination.—Acute gastro-enteritis was present, as also hemorrhagic nephritis with albumin and bile present in the urine. There was no manganese detected in the urine.

From its behavior towards the heart it would hardly be expected that this drug would produce any vaso-constricting influence on the vessels, but as some authors* speak of it as possessing such an action it may be well specially to mention it here.

This experiment shows that manganese is absorbed from the conjunctiva and that it has an action on the blood in the organism as seen in the formation of the brown spots.

The chloride of manganese and iron has been used by Pétrequin in perference to the simple perchloride of iron, as a local hemostatic; in Italy it has been applied to necrosed bone, and injected into fistulous tracts and hydroceles, but it has no advantage over other remedies.

The same remark applies to the use of an ointment made with the oxide of manganese (two drachms to one ounce of lard), which has been recommended in scabies and ringworm, and combined with sulphur in prurigo. The potassium permanganate treatment for chronic local patches of eczema is sometimes indicated; after removal of crusts the reddened surface is dried and painted with one in ten solution in water, once or twice daily, until a black adherent covering forms, and this is left on for six to seven days before separating. The application is painful at the time, but I have found it effective; it is suitable only for covered parts. A weaker solution is used as a lotion for ulcerations and suppurating wounds and as injection in leucorrhea, ozena, empyema, gonorrhea, etc., for which the zinc permanganate is specially good, while the calcium compound is best as a wash or spray in stomatitis or diphtheria. The pink or green color rapidly changes to brown on contact with discharges, which may be considered disinfected when the injections return unchanged. Brown stains may be removed by sulphates or oxalic acid in solution.

In snake poisoning the admixture of potassium permanganate with venom rendered it inert, and Lacerda reported that intravenous injection of a one per cent solution soon after one of snake poison, proved antidotal in dogs. Vincent Richards found that if the salt were injected into the puncture sufficiently soon, ill-effects were prevented. Twenty minutes of a two per cent solution freshly prepared should be injected under the skin in two or more places, and especially into the orifice made by the fangs, for it is essential that it should come into actual contact with the poison. It must be remembered that this is a chemical, not a physiological antidote. It by no means precludes the use of antivenine.

The value of permanganates in opium poisoning, suggested by B. Smith in 1884, has been amply demonstrated by W. Moore and others. The former took five grains of morphine sulphate in one ounce of water, and a few seconds afterwards eight grains of potassium permanganate in eight ounces of water, and found no narcotic effects whatever. A case where sixteen grains was taken recovered after three doses of five grains each of the antidote. Analysis of vomit mixed with known quantities of both drugs proved the morphine was no longer detectable.

* Nothnagel and Rossbach, Hoppe-Seyler, finds that sulphate of manganese produces very marked constriction of the vessels, and also paralysis of the heart and intestines.

The proper proportion is six grains of the antidote for each ounce of laudanum taken, if known, or if unknown, eight to ten grains in four to eight ounces of water. The stomach should be washed out with a weaker solution two or three times at intervals of half an hour. When swallowing is difficult the remedy may be given by nasal tube or by hypodermic injection.

Free chlorine is readily and cheaply generated by acting on peroxide of manganese with hydrochloric acid, or by heating a mixture of common salt and peroxide with sulphuric acid and water in equal parts. The former process is recommended in the Swedish Pharmacopeia, one part of peroxide and four of acid being ordered; the latter process is known by the name of Guyton Morveau. A mixture of manganese oxide, seven and one-half grammes, and ten grammes of salt, with sulphuric acid and water, of each twenty parts, will disinfect a space of thirty cubic meters. A saturated solution is five per cent, and when diluted five hundred times is suitable for lotions, disinfection of hands and of stools in typhoid, and for the disinfection of drains. It disintegrates fetid and decom posing organic substances, and destroys bacteria, but it is not now less frequently used than carbolic acid.

I have mentioned that Ure found one to two drachms of the sulphate act as a cholagogue purgative, and Goolden gave it in cases of enlarged liver with dark or pale stools and jaundice, when no abscess or acute symptoms were present. Most of the patients (at the Dreadnought Hospital) were in a weak condition, having returned from India, and he sought for a non-mercurial remedy to stimulate the liver, and found that ten or twenty grains of sulphate of manganese, though at first it excited nausea or vomiting, soon acted on the bowels to the marked relief of the patient, and with rapid clearing away of the jaundice. This favorable result has not been corroborated by others, but Goolden has written further, stating that he has used the remedy with success in hepatic dropsy, hemorrhoids and bronchial congestion.

Leared found that oxide of manganese had decided power in relieving gastrodynia and pyrosis. In the cases in which he describes benefit, epigastric pain, severe and radiating, coming on not immediately, but soon after food, especially after albuminous food, were the prominent symptoms. Pyrosis and vomiting were sometimes present. The tongue was generally red and patchy, and there was a rapid shedding of the epithelium, and exposure of the hypersensitive mucous surface. Bismuth is an excellent remedy for such a condition, but Leared found manganese relieve it more quickly, and without causing constipation. He reports two cases of gastralgia, "severe pain with occasional vomiting," one case of derangement of the stomach, sympathetic with that of the uterus, and one of pyrosis, with "irritable mucous membrane;" all these got well quickly with ten-grain doses of the oxide.

The real therapeutical use of manganese is in the treatment of amenorrhea. For this purpose it was originally recommended by Ringer and Murrell, and their observations have been amply confirmed. By amenorrhèa is meant the functional condition, not suppression of the menses due to organic uterine disease or to pregnancy. It proves most efficacious in cases in which the flow has ceased from exposure to cold. It will not succeed when anemia is the cause of the trouble. In these instances a preliminary course of iron is necessary to ensure success. The permanganate is not easy of administration. Dissolved in water it forms a solution which is nauseous, and the taste of which is not readily covered by any of the ordinary flavoring agents. It may be given in two-grain tablets, but caution is necessary in their administration, for if they adhere to the mucous membrane of the esophagus or stomach they act as an escharotic, and may inflict a considerable amount of injury. They should be given only after food, and should be followed by a copious draught of water or other fluid. The permanganate may be made into pills with kaolin, but the same precautions as to administration will have to be observed.

At a later period, Murrell advocated the use of the binoxide in this condition, and it certainly has many advantages over the permanganate. It is not caustic, and may

be given either in powder or in the form of a tablet. Its administration should be commenced some four or five days before the expected period. Murrell has also published cases in which the citrate of manganese has yielded good results. When the amenorrhea is due to anemia the citrate of manganese and iron may be prescribed, but as the amount of iron in this combination is small, it would be better to give the sulphate or the perchloride of iron first, reserving the manganese until the condition of the blood is improved.

Speaking generally, it may be said that although the sphere of action of manganese is limited, it is deserving of more attention as a therapeutical agent than it commonly receives.

[Written for the MEDICAL BRIEF.]

Opium Eating and Smoking.

BY DONALD MACLAREN, M. A., M. D.,
London, England.

NO. II.

As I pointed out at the conclusion of the last article, there is nothing immoral in smoking opium. Morals are pretty much a question of geography. As Sir William Moore very justly points out, many customs which are tolerated and recognized by us would be considered immoral in countries where opium smoking is indulged in without reproach. Our modern balls and drawing-room dances would excite the astonishment and derision of many nations which it is our pleasure to regard as less civilized than ours.

Lord Wolseley, who is nothing if he is not outspoken, says: "If we are sincere in wishing to stop intemperance let us set to work in this monster Babylon in which we live. The sincerely moral man, who does not live on a pabulum of sentimental claptrap, purifies his own house and home before he undertakes distant crusades. We only make ourselves ridiculous by declaiming against what we style sins which we sanction around us. When I see strong measures taken in England to prohibit the sale of poisons in the form of spirits of all sorts, I shall believe in the new reformation. It is to me, in our present state, the most monstrous imposition and humbug to preach abroad what we dare not carry out at home."

The editor of a well-known Calcutta medical paper, says: "When England has purified her home life, when she has shut drunkenness out of her cities, then only may she go to the nations of the earth, and, having clean hands, bid them boldly to purify themselves from all evil."

Surgeon-General Mouatt tells us that while there are ten thousand four hundred and seventeen shops licensed for the sale of opium in British India, with a population of two hundred and twenty-two million, there are one hundred and eighty-four thousand seven hundred and forty-three for intoxicating liquors in England and Wales, with a population of twenty-nine million.

As to opium being always destructive to health, that I utterly deny, unless it is taken in excessive quantities, and, as before observed, nearly everything would be destructive to health if used in excess. When I was examined by the Opium Commission, says Sir William Moore, I mentioned that life insurance companies did not charge extra premium to moderate opium smokers, which, apparently, was received with doubt by the commission. The secretary of the Oriental Life Insurance Company states that the Oriental company, which insures more native lives than any other, has not had to deal with a death from opium for twenty years. Out of nine hundred and seventy-three death claims in twenty years, insuring in the aggregate thirty-four lakhs of rupees, there was not a single one of them attributable to the use or abuse of opium. Many suppose the use of opium must cause torpor, lethargy, and sleep, so unfitting a person for business. But the first action of opium on the system is exhilaration or excitement. As regards effects, I compare several pipes of opium to a glass or two of champagne. It brightens the intellect, temporarily strengthens the system and promotes physical activity and digestion. I liken several more pipes of opium to several glasses of brandy and water. The person becomes drowsy; but there is this difference, opium never develops the quarrelsome stage which so generally precedes the

drowsy stage of alcohol. The opium smoker's attitude is always one of repose. The opium smoker is peaceful without being quarrelsome. He gives the police no trouble, as the devotees of alcohol do. The Chinamen in Calcutta, all opium smokers, are the most healthy, peaceful, and industrious of all classes, and it is rare to see a Chinaman in a police court. In his "Lives of Bombay Opium Smokers," Mr. Pestonjee says: "From the statistics of crime during the last eight years, it appears there has not been a single case of criminal offense originating from opium."

In my description of the opium shops of Bombay, I said: "When a person begins to smoke, his faculties appear devoted to the matter in hand, and all his attention is directed to the manipulation of his pipe and lamp." The appearance of many of the people at the opium shops is very characteristic. There is no joviality perceptible among them, as there would be among a number of persons indulging in liquor. On the other hand, there is no noise or quarreling, as would certainly result from liquor. The different stages of alcoholic inebriety, the friendly, the argumentative, the captious, the communicative, the sentimental, the quarrelsome, the maudlin affectionate, and the extremely drunk, have no place in the opium house. A little conversation may take place, but it is in low strains, and principally between those settling down for their smoke. The different expressions of feature are a study. Here is one showing that stern and passive repose which, according to Epictetus, is happiness. Here is one whose countenance expresses perfect inanity, and who, like "my Uncle Toby," has "no desire to trouble his brain with abstract thinking." There is another, not yet under the influence of the drug, bowed in a meek and suffering manner, probably from rheumatic pains, and looking as miserable as if he had spent the day in reading a pamphlet on cholera-morbus or self-mortification. He flies to opium "to mitigate the ills he can not shun;" but "not poppy nor mandragora, nor all the drowsy syrups of the world" will in this life afford him more than temporary relief. On this one's face there is a vacant smile, for he is the victim of an ecstatic and pleasurable dream. But a few minutes ago, doubtless, "his bones were filled with aches." It may be that the very absence of pain under the magic of opium causes the gleam of pleasure on his face. Were he acquainted with the quotation he would probably exclaim: "If 'twere now to die, 'twere now to be most happy:" Next are the worn and well-marked features indicating some chronic internal disorder, probably hepatic. For in India—

> "The liver is the lazaret of bile, but very rarely executes its function,
> And the first passion stays there such a while, that all the rest creep in and form a junction."

He, also, is doomed; but opium will probably prolong and certainly smooth his remaining span of existence. Depriving him of opium would be a positive cruelty.

The physical attributes of many of the frequenters of the opium houses are not of a high order. Some are, apparently, old enough to be a legacy from a past age, or an importation from Pompeii. Many of the habitués, although not in reality old, are yet wizened, prematurely old, and debilitated. Most, like Cassius, have "a lean and hungry look," as if suffering from famine. "Sleek-headed" men are in a minority. Many enter like animated charnel houses, with merely skin and flesh enough to conceal the pathological horrors they contain. *Yet this is not attributable to opium.* It is the general mode of life, the unsanitary surroundings, want and disease, which produce a similar class in other large cities where opium is not smoked, and where gin takes its place. This person suffers from a bad cough, and is, evidently, asthmatic or consumptive; that person is weakened by rheumatism; a third is shivering in the cold stage of ague; a fourth has some irritating and painful skin disease; a fifth has suffered from want of food, and "to appease the hungry edge of appetite" flies to opium, as the others have recourse to opium for the relief of pain. Probably two-thirds belong to one or other of the classes referred to, and, in my opinion, they do much better for themselves by smoking *chandul* than they would do by drinking gin or native liquor. Those who cast the stones with such virulence, and so promiscuously, at these poor opium-

smokers, do so in ignorance, and without the grace of that best of virtues—Charity. They ignorantly regard the maladies they see in opium houses, not as diseases for the relief of which opium is taken, but as the effects of opium, and on such mistaken grounds they uncharitably condemn. Doubtless some take to opium without the excuse of any malady, simply as a solace against the worries of life, just as some people take to drinking, and others commit suicide, to avoid the evils of existence. The Hindu or Mohammedan, with greater philosophy than the average European, takes to opium smoking. In the magic of opium he finds such content that he would not trouble himself so much as Diogenes did if Alexander appeared between him and the sun. *That* content, the virtue of prosperous people is, however, of quite a different order. Abstinence is so much more pleasant on the other side of indulgence. Men having a good digestion, which somebody coupled with a bad heart, after dining sumptuously, may leave their domestic bliss, and with full pockets attend the meeting of the Anti-Opium Society, and there condemn opium smokers, one and all. The Pecksniffian strain so often adopted may be paraphrased into "Oh! my worldly friends pursuing the phantom of pleasure through the guilty mazes of opium dissipation, how easy it is to be happy if you will only be good!" But a person ignorant of the motives which lead to opium smoking is unable to differentiate between the use and abuse of the drug, and is altogether uncharitable to the defects of human nature.

When the use of opium is abused, there is no doubt that it produces bad effects. The first result is constipation and disturbance of digestion. The digestion becomes slower. Partially digested food passing into the bowels acts as an irritant, and excites diarrhea, with consequent emaciation. As a matter of fact it is but a small minority of opium users who take it to excess. We do not propose the abolition of alcohol because of a few dipsomaniacs, and there is really no valid reason why the abolition of opium should be proposed because of a few opiomaniacs. It has been said that the use of opium is more deleterious than the use of alcohol. This I altogether deny. It is well known that the excessive use of spirits causes fatty degeneration, disease of the liver, kidney, brain, heart affections, paralysis, and often the active delirium known as delirium tremens. Opium does not cause anything of the kind. In excess, as previously mentioned, it causes slow digestion, consequent diarrhea and following emaciation. Yet although this is the case in exceptional instances, the total benefit derived from opium far counterbalances the occasional injury. The statistics of the lunatic asylums of India, while showing that many develop insanity from spirits, or from bhang, show that only very few become lunatics from indulgence in opium. The anti-opiumists would abolish the use of opium, except when ordered by a physician as a medicine. If this were done it would be a most grievous interference with social habits and customs of large sections of the people of India, such as no government has a right to impose. For example, opium is an important dietetic factor in enabling men to undergo continued hard work without breaking down. The Rajpoot would not be able to offer the stirrup cup of usual pawnee (opium water) to his friend, as the latter leaves in the grey of the morning, or with the rising of the moon, for a twenty or thirty mile camel ride through the sands of Marwar, Bickaneer or Jeysulmere. Neither would the rider be able to share his opium with his camel or horse, which, especially before the days of railways, was a point of honor with the rider. The camel feeders who take young camels into the desert districts would not be able to subsist on their bag of grain and camel's milk without opium.

Some time ago, one hundred Sikhs were lent for service under the East African Company. As might be expected, some were regular opium eaters, and had seen much hard service without ever having been on the sick list. The boatmen of Bengal, who, after a hasty morning meal, are able to tow a heavy boat all day, would lose their power of doing so without opium. The opium pipe could not be introduced as now, when, after the evening meal it takes the place of the wine or spirits or tobacco consumed in other

countries. The presentation of the opium cup at social gatherings means welcome and good-fellowship. But anti-opiumists cry out against this custom, yet do not object to promote sociableness by means of the wine cup or "pegs."

The person suffering from want of food would not be able to appease his hunger by the customary dose of opium, and when scarcity or famines occur, thousands more would die than before. Neither would the dwellers in malarious districts protect themselves from fever and ague by the use of opium. The dwellers in the Terais especially believe that without opium they would succumb to the miasm, and the same belief in the prophylactic properties of opium is entertained in the fen districts of England.

As before observed, one of the constituents of opium, anarcotine, has been proved to possess great anti-periodic powers. But without considering these special powers, opium smoking in small quantities excites the circulation, and produces a glow throughout the body. In large quantities it soothes the system and blunts nervous sensibility. Both actions are antagonistic to chill, and chill is the first stage of malarious fevers, especially of ague. The Indian, after working and perspiring all day under a tropical sun, is very likely to become chilled by the night fall of temperature, and this liability is increased by his carelessness in not using extra garments. But he comes home, and after, or sometimes before, his evening meal, he takes his opium. As a consequence, instead of feeling cold and shivering, he remains warm and glowing, and so escapes chill, which if not the real and only cause of malarious fever, is certainly the cause of many repetitions of attack.

But perhaps the worst effects would fall on the frequenters of the opium shops who go there to obtain relief from some painful malady. What has been done in the Punjaub and Bombay in the way of suppressing opium has resulted in the formation of opium clubs, and in persons smoking at home.

I find the following in a Bombay paper: "Formerly there were twenty licensed smoking houses. These houses were, under a Government resolution, closed in August last. Since then as many as fifty private clubs have been started where persons collect and smoke opium. While the licensed shops were not allowed to be kept open after ten P. M., the private clubs are kept open night and day. A Government official went to see a few of these clubs. As he entered, some of them —smokers—tried to run away, when an old man of seventy-five years of age, and of excellent physique, got up in a rage, and in a loud tone said, 'You cowards, why do you run away? Stay and smoke. Will they cruelly deprive us of our neces sity? We shall fight it out; at the worst they will kill us.' If what the old man said represents the general feeling of the opium smokers, we are certainly no nearer the solution of the problem than we were. Is it not strange that during the riots, when all the shops situated in Bhendy Bazaar were closed, the opium shop situated in that locality, and owned by a Hindoo, was kept open, unprotected either by the police or the military, and as usual the Mohammedans were purchasing their daily quantities. Yet no attempt was made by the Mohammedans to beat or otherwise molest the Hindoo shopkeeper."

The opium-eater's soliloquy runs as follows:

I'd been cheered up at my chandoo shop, for years at least two score,
To perform my daily labor, and was never sick or sore;
But they said this must not be;
So they've passed a stern decree,
And they've made my chandoo-seller shut his hospitable door.

If I'd only cultivated, now, a taste for beer and gin,
Or had learned at pool or baccarat my neighbor's coin to win,
I could roam abroad o' nights,
And indulge in these delights,
And my soul would not be stigmatized as being steeped in sin.

But as mine's a heathen weakness for a creature-comfort, far
Less pernicious than their alcohol, more clean than their cigar.
They have sent their howlings forth
From their platform in the North,
And 'twixt me and my poor pleasure have opposed a righteous bar!

A New Operation for Large Oblique Inguinal Hernias.

BY JAMES U. BARNHILL, A. M., PH.D., M. D.,

Professor of the Principles of Surgery and Clinical Surgery, and Chancellor of the Ohio Medical University; Surgeon to the Protestant Hospital; Editor of the Columbus Medical Journal.
Columbus, Ohio.

Notwithstanding the great improvement in hernioplasty in the last few years, the percentage of failures is still quite considerable—from three to five per cent—in the hands of the most skilled operators, and doubtless a much larger per cent in the total number of cases operated upon. The number of hernias which still go untreated is witness to a lack of public confidence in operative procedures.

An analysis of failures in general shows (*a*) that after operations for the restoration of normal inguinal canal and those done by the Bassini method, recurrences result from weak union of the longitudinal fibers of the internal oblique to Poupart's ligament, and this, too, in a certain number of cases, notwithstanding every possible precaution has been observed; and (*b*) that after the typical transplantation operation there are occasional protrusions at the situation of transmission of the cord, and also that there are occasional cases of atrophy of the testicle. The latter effect has usually been attributed to the excision of too many veins, but I am satisfied that pressure upon the cord by the tense fibers of the coapted flaps of the external oblique aponeurosis is an important factor in producing this result.

For most cases, doubtless the Bassini, Halstead, Bloodgood, Ferguson, Andrews or other standard operations should be employed, slight modifications in individual cases giving excellent results; but in quite a number of cases combinations of methods, or new methods, may be worth trying.

This operation is devised for all cases in which imbrication is indicated, especially for large oblique inguinal hernias, with distended abdomen, displaced and partially obliterated conjoined tendon and poorly developed rectus muscle. In large inguinal hernias with considerable extension of the aponeurosis of the external oblique, and those with pendulous abdomen, imbrication of the layers of the aponeurosis of the external oblique may greatly augment the strength of the wall, and the creation of a new canal between the imbricated layers of the oblique aponeurosis, as recommended by Andrews, has additional advantages in preventing recurrences. With a view of preserving these advantages and avoiding possible compression between the edges of the aponeurotic flaps, the cord is passed through an incision in the edge of the flap rather than sharply flexed over the border. In the completed operation the cord passes through the external oblique aponeurosis just above the middle of the canal, and instead of passing between the taut edges of the coapted flaps it is transmitted through a transverse incision in the upper flap, thus strengthening the lower half of the posterior wall with the aponeurosis, as Halstead formerly did the whole canal.

The technique of the operation is as follows:

1. The skin and superficial fascia are divided from the spine of the pubis slightly beyond the internal abdominal ring. The aponeurosis of the external oblique is then incised to the same point, leaving the lower flap of fairly good width. The sac is then separated from the cord, freed of intestine, transfixed, ligated high up and excised, the stump being permitted to retract through the internal ring.

2. If there be varicose veins they are ligated and excised. The transversalis fascia and internal oblique, including the conjoined tendon, are then stitched to the shelving portion of Poupart's ligament, one or two stitches being placed in the internal oblique muscle above the point through which the cord passes, with a view of obliterating the inguinal fossa; the cord being brought well down to the border of the internal oblique, thus giving it considerable obliquity in passing beneath the muscles. Thus the posterior wall of the inguinal canal is in a large measure restored.

3. The lower border of the superior flap is stitched to the under side of the

inferior flap close to Poupart's ligament with mattress sutures—three such sutures being placed in the upper part of the incision over the muscle and cord, the other four being placed beneath the cord. A small incision sufficient to make an opening large enough for the passage of the cord is made in each flap; in the upper one at a point one inch below the internal abdominal ring, in the lower flap at the junction of its lower and middle third, thus permitting the cord to pass obliquely through artificial openings in each layer of the external oblique aponeurosis.

4. The mattress sutures having been tied, the cord passes through the opening in the superior flap and is placed between the imbricated layers of the aponeurosis until it reaches the incision in the inferior flap through which it is passed and the lower inferior flap is then stitched to the upper one with an overlapping of from two to three inches, as the case will permit. It will be thus seen that in its upper third the cord is in its normal situation. In its middle third it lies between the aponeurotic flaps, and in its lower third it is transplanted anterior to the aponeurosis.

5. Both layers of the superficial fascia are then approximated, closed with subcuticular silk-worm suture and covered with a layer of gauze and flexible collodion.

It will be seen that this operation is a combination of Andrews' method of imbrication and Halstead's method of transplanting the cord, though the transplantation in this case only applies to a small portion of the lower part of the canal.

The distinctive feature of the operation consists in the transmission of the cord: (1) through both flaps at different levels; (2) through incisions rather than between the edges of the flaps. This procedure gives greater obliquity to the canal, more valve-like value to the consecutive structures forming the anterior wall, less liability of compression of cord at point of transmission through the aponeurosis and, as it seems to me, a stronger abdominal wall at the point of transmission.

A simple demonstration will show that there is much less liability of the cord being unduly compressed when it is permitted to pass through an incision as here recommended than when it passes around the edge of an imbricated flap. In the former case the severed fibers contracting tend to make an opening, while in the latter a slight increase in tension from whatever cause tends to strangulate the cord and thus cause atrophy of the testicle.

At the points of transmission we will have an active regeneration of connective tissue fibers forming strong and unyielding bands much stronger than can be secured by the adhesion of the longitudinal fibers as approximated in the old operation.

If there be any apprehension of weakening the aponeurosis by the incisions made in it for the passage of the cord, one may be reassured by thinking of the facility and completeness with which connective tissue regenerates, as is illustrated in the regeneration of a severed tendo-Achillis for talipes equinus, and also in the unimpaired strength of the reunited tendon.

The severed fibers reunite, as already explained, around the cord, thus providing a more or less firm band around it and insuring strength to the aponeurosis as a whole. It is quite improbable that an equally strong resistance can be secured by adhesions between longitudinal fibers of the same kind or between muscle and tendon.

Of course, it will be understood that this operation is not recommended for the ordinary case of hernia. In this we get almost perfect results by the simpler methods. In all such we should simply aim to restore the parts to their normal position, but the method here described has special advantages in dealing with large oblique inguinal hernias, especially in cases in which the conjoined tendon is weakened or partially obliterated and the rectus muscle narrow. The posterior wall of the canal is strengthened and additional resistance to the hernial protrusion is given at the point of the passage of the cord through the external oblique aponeurosis, partly by the strength of the fibrous rings themselves and also by the increased valve-like pressure on account of the greater obliquity of the new canal. The cord is abundantly covered in its lower two-thirds by the aponeurosis of the

external oblique and below this by the layers of the superficial fascia, adipose tissue and skin.

It is now five years since I performed my first operation by this method, and this case, together with several others since that time, have been entirely successful.

248 East State Street.

[Written for the MEDICAL BRIEF.]

Sulphate of Copper in the Treatment of Typhoid Fever.

BY J. F. STEVENS, A. M., M. D.,

Dean of the Nebraska College of Medicine; Medical Department Nebraska Wesleyan University; Professor of the Principles and Practice of Medicine in Same.
Lincoln, Neb.

Copper is one of the most potent algæcides known. Under favorable conditions 1 part of copper per 1,000,000,000 suffices to destroy spiogyra. A large majority of algæ are destroyed by 1 to 3,000,000. The colloidal solution of copper, produced by the action of water upon metallic copper surfaces, proves to be the most destructive. Possibly this is due to the perfect solution formed. Nor is copper fatal to algæ alone. Under favorable conditions the bacilli typhi abdominalis succumb to a dilution of from 1 to 100,000 to 1 to 500,000. As with the algæ, the colloidal solutions are immensely more potent than solutions of the copper salts. Of the salts the sulphate proves the most actively destructive, possibly because of its solubility. Mercuric chloride is but slightly more fatal to typhoid germs than copper sulphate. Carbolic acid, thymol, formalin, naphthaline, sulpho-carbolate of zinc and other accepted antiseptics take low rank in comparison.

These facts, together with a knowledge of the mild toxicity to the human family, suggest at once the possible value of the drug in the treatment of typhoid fever. Experience teaches that a six per cent solution of the salt is the most convenient. Remembering that copper is notoriously liable to be contaminated with arsenic, care must be taken to procure a perfectly pure drug. Beginning early in the disease, two drops of this solution diluted in one-half glass of water should be given hourly. An occasional sensitive stomach will call for a reduction of the dose to one drop. One drop will contain about one-sixteenth of a grain. If the tongue becomes dry, the dilution may be slightly acidulated with aromatic sulphuric acid. If the breath becomes foul, moderate doses of baptisia will prove useful. Patients should be continued on the treatment until convalescence is well established, when the drug may be stopped and small doses of strychnine substituted. During convalescence the pulse rate will frequently be found subnormal. This is probably due to the action of the copper on the nervous system and need cause no alarm. The same phenomenon is often very marked in cases treated with sulpho-carbolate of zinc. Both drugs act as a sedative to the nerves. When cases are seen early, before there is marked degree of intestinal ulceration, the use of large colonic flushings containing from five to ten grains of copper sulphate to the quart prove of very great value in shortening and lightening the course of the disease. The writer has seen such decided results that he can speak with much confidence. Good judgment must be exercised in this as well as in any other treatment. The patient's hips should be slightly elevated and the solution be allowed to enter slowly. Two quarts should be used hourly for several days. After retaining the enema for five or ten minutes, the patient may relieve himself, using a bed pan. Should the treatment irritate the bowel, reduce the drug strength, or use once in two hours instead of hourly. It is my custom to use the remedy thus for three days, then use once in three hours for several days, after which the intervals between are gradually lengthened until once daily yields to non-use.

During the autumn and winter of 1906 and 1907 fifteen cases of typhoid fever were treated with copper, all of whom recovered. Six of these cases were treated in St. Elizabeth Hospital, and nine in private families. The youngest was nine years old and the eldest thirty-seven. One was a case of walking typhoid. The six hospital cases came from a railroad construction camp and, with the exception of two, were well advanced in the disease

when admitted. The railroad cases were of a bad type, patients being delirious and in several instances having hemorrhages. Cases in private practice were seen much earlier in the disease, ran a milder course, convalesced sooner, and on the whole presented more gratifying results. Two of the hospital cases received the colonic flushings above referred to in addition to the remedy per orem. Bowel washings were omitted in the other four cases, because of great abdominal tenderness and very evident profound ulceration. Eight of the cases in private practice received injections. In one family having two cases, one patient was already in the course of the second week of the disease when first seen. The second case coming under treatment early, was treated by flushings and convalesced at the end of two weeks, after running a comparatively mild course. Another young man of eighteen who had been ill one week when first seen and whose case was typical in point of prodrome and beginnings, had a normal temperature at the end of fifteen days. The last case treated was a girl of ten years who, at the end of two weeks, presented a normal temperature. This case received colonic flushings three times a day only, owing to the fact that she was rebellious, and was treated throughout by reduced copper in the place of copper sulphate solution. A trituration was made with sugar of milk, representing one five-hundredths of a grain of copper to one grain of sugar of milk. Of this ten grains was administered hourly during the day, the doses being reduced as the patient improved.

Diet in all of these cases was, in the main, buttermilk. At no time was sweet milk given. Skimmed and strained soups were used, particularly tomato soup. The juice of ripe tomatoes, expressed and strained, was given to such as liked it, in quantities of from one-half to one wineglassful a number of times daily. As the case convalesced, tapioca was gradually added to the diet. The nurses were instructed to insist that the patient partook of goodly quantities of water. If the tongue became dry, a few drops of diluted hydrochloric acid was added to the water, which proved very grateful to the patient. When the temperature had been normal one week, the diet was carefully changed into semi-solid foods, and later on into the food of health. These cases, in addition to forty-three reported in the *Western Medical Review*, November, 1906, make a total of fifty-eight cases treated on the copper plan, with one death. The patient who died was very far advanced in syphilis, so much so as to make recovery impossible under any circumstance.

It would seem that this list serves to establish the fact that copper is one of our most reliable remedies in the treatment of typhoid fever. Like other remedies, however, it must be used with good sense and every possible chance given the patient in all ways for recovery. Absolute quiet, absolute rest, careful nursing, constant attention to details, are all necessary. Without these, failure must usually come in the treatment of any serious disorder.

The case in which reduced copper was used instead of one of the salts, proved particularly happy in the outcome. So much so, as to suggest further study and trial in this direction.

[Written for the MEDICAL BRIEF.]

Points to be Kept in Mind in Connection with the Administration of Chloroform and Ether as Anesthetics.

BY H. J. H. HOEVE, M. D.,
Professor of Anatomy in Drake University College of Medicine.
Des Moines, Iowa.

In many private cases, and even in a great many hospitals, an observant eye finds at once that the examination of patients regarding the determination of the anesthetic to be employed, is frequently limited to auscultation of the heart of the patient and a nodding of the head of the examining physician. The urine examination is slighted in many cases, as though it were of no import to know whether chloroform or ether should be used. Because of the laxity in examination in regard to selecting the proper anesthetic I have prepared the following classification:

Chloroform, and not ether, should be used in the following cases:

1. In affections of the respiratory organs, where ether would cause too much

irritation. 2. In nephritis. 3. In labor cases. 4. For children. 5. Cases on the battlefield. 6. In hot climates. 7. Cases where actual cauterization is necessary. 8. In abdominal sections, if the bowels are distended with gas, and where coughing and vomiting, which are more frequent with ether, must be prevented.

Never use chloroform for a second anesthetic within a week from the first administration.

Ether should be used as follows:

It should always be preferred, wherever possible, except at the induction of narcosis.

One of the main points in classifying cases is to remember that ether is much more irritating than chloroform, and consequently produces a more abundant secretion from the mucous membranes. It may also produce an irritation of the stomach through the saturated saliva. The fact that ether possesses greater power to irritate is proved by the fact that it requires but five per cent of air to properly dilute it for anesthesia, while chloroform requires ninety-five per cent of air.

Preparation of patient. (Bryant.)

Make an examination of the patient from top to toe.

Examine the secretions.

Make a record of the pulse and respiration.

No food six to eight hours before operation, except a glass of milk.

Remove false teeth, if there are any.

Loosen everything that constricts the body anywhere.

Cause the evacuation of the bladder and rectum.

Have enough fresh air in the operating room.

Relieve patient's fear.

If, during an emergency, an anesthetic must be administered without emptying the stomach, then the best thing to do is to pass the stomach tube after the patient is under the anesthetic.

All constriction should be removed, as the heart will have enough work, and any pressure upon the capillaries in different areas would impede the circulation greatly.

Position.—The horizontal position is necessary. The head should be on a level with the body, and if the patient should insist upon a pillow, it must be removed as soon as the anesthetic begins to take effect. A small roll may be placed under the shoulders and neck to free the respiratory passage.

The teeth of the manible should be kept anterior to those of the upper jaw. This is accomplished by pressing the manible forwards. This frees the larynx. It is impossible in this position for the tongue to fall back upon the epiglottis. The points to be kept in mind now are:

(*a*) Allay the patient's fear.

(*b*) Take care of his comfort.

When a patient holds himself down by his will power, he will struggle as soon as his will power is anesthetized. In order to allay his fear, it may be well to give a little morphine and atropin hypodermically. In some cases one-half to one ounce of whisky may be administered. The patient should be kept as dry as possible. Attention should be paid to the position of the extremities. Paralysis has been caused in not a few cases by permitting the extremities to rest on the edge of the table. The arms should be drawn up to the shoulders; the nose and lips should be anointed with vaseline or cold cream in order to prevent irritation; the eyes should be covered by a towel for the same reason. If the head is turned to one side the saliva accumulates in the cheek on that side, and can easily be wiped out by means of a piece of gauze.

The temperature should be carefully watched, as the anesthetic has a tendency to decrease it. The patient should be kept well covered.

The anesthetizer has absolutely no business to watch the operation; if he attends to his duties properly he has no time for anything else.

Chloroform is nearly always used to begin the anesthesia, if it can be had. Nitrous oxide serves the same purpose, and is probably better. It requires a great deal of judgment in the first stage as to the concentration of the vapor.

In administering the ether the cone is first held a few inches away from the face, permitting greater dilution; so, when the cone is placed down squarely upon the face, the patient breathes in the natural way; not quicker than normal. As soon as the respiration is normal the anesthetic

may be pushed. The maximum dose of chloroform to be used is sixty minims a minute, the usual dose is twelve minims, and the minimum dose six minims a minute.

When the respiration becomes irregular, it is necessary to dilute the vapor by lifting the cone. This is also necessary when the patient holds his breath on account of the deep inspiration, which will shortly follow.

Involuntary muscular contractions are frequently present. If there are struggles, the mask must be partly removed on account of the danger of heart paralysis. In the first period the anesthetic is given very slowly; in the second, push it, and in the third period be very careful.

During the second period, semi-consciousness, the patient has lost control over his muscles, but the reflexes are still present. In cases of confinement, colic, or reduction of dislocations, it is not necessary to push the anesthetic further, but from statistics it is dangerous to operate at this stage, because the reflexes are still present, and a reflex might cause paralysis of the heart. If semi-consciousness is required; as in confinement, no more anesthetic is used until the patient begins to move. This is the dividing line in reality, between surgical anesthesia and semi-anesthesia.

The Most Valuable Reflexes:

1. Pharyngeal—swallowing movements.
2. Conjunctival—touching the lower margin of the upper eyelid.
3. Deep pupillary reflex.

1. The pharyngeal reflex is due to ether vapor irritating the back of the pharynx, and the swallowing movement are the results.

2. In order to obtain the conjunctival reflex, pull the upper eyelid upwards, and touch the lower margin, the result will be wrinkling of the lower eyelid.

Remember, then, that as long as the reflexes are present, the patient is not ready for operation. If the eyes should resist opening, then you do not have to test for the conjunctival reflex. It is a fact that the eye muscles are affected very late, and as soon as they are affected the patient is ready for operation.

A good way to avoid vomiting is to give enough ether to have the pupils a little dilated. The chief indication that the patient is too deeply anesthetized is heavy snoring; this is due to paralysis of the soft palate. There are certain signs, called danger signs, which indicate that the patient is too deeply anesthetized.

Danger Signs:

1. In connection with the pupil.
2. In connection with the respiration.
3. In connection with the pulse.
4. In connection with the skin.

1. Withdraw the anesthetic at once if the pupil is dilating, and the superficial reflexes do not return.

2. Watch the respiration carefully; if it is bad, compress the epigastric region a few times, the patient will respond with a deep inspiration, and the danger is passed.

The pulse does not always become irregular before it increases in rapidity. If it runs up to one hundred and forty or one hundred and fifty, then it is necessary to use pilocarpinæ hydrochloras, 1/40-grain, hypodermically, or if this is not successful, salt solution.

The respiration must be carefully watched. If artificial respiration is induced immediately after the cessation of the respiratory centers, the chances, according to some good authorities, are ninety-nine out of a hundred that the patient will recover.

In giving an anesthetic it must be remembered that the patient is nearer death than life. He may die at any time, after a few whiffs, or after the operation is over. Probably the most frequent cause of death is the early paralysis of the heart. This occurs before complete insensibility has set in, and is usually due to concentrated vapor reaching the heart. If the patient has been struggling, the next few inspirations being much deeper than the rest, will saturate the blood to the utmost, and the blood passing into the heart reaches the coronary arteries, and the heart stops reflexly. The same condition may also be brought about by irritation of the mucous membrane of the nose. It is the result of too great irritation of the vagus nerve, resulting in reflex inhibition, but the same kind of irritation may cause the heart to start again. Therefore, the point is to prevent too much irritation of the respiratory tract.

The late paralysis which sometimes occurs, is due to the weakened condition of the centers in the medulla, whenever an operation lasts a few hours. The vaso-motor center is the first to stop, and the last is the respiratory center. When the vaso-motor center is stopped, all the vessels relax, and the blood goes through the arteries into the veins. This, of course, might cause death by cutting off the blood to the respiratory centers, or it might be due to direct poisoning of the respiratory center, but in most cases it is due to anemia. This is also the reason why a patient should not be anesthetized in the sitting position.

Routine treatment for vaso-motor paralysis:

1. Inversion of the body.
2. Mechanical excitation of the heart.
3. Thermal excitation of the heart and vessels.
4. Chemical excitation of the heart and vessels.

1. Invert the table, permitting the patient's legs to hang over the foot end; the knees will form a firm hold. This does not bring the blood in the heart back to the brain, but that which is in the veins below the diaphragm into the right auricle, and a contraction follows.

2. Pressing the region over the heart at the rate of about one hundred and twenty a minute.

(*b*) Squeezing the heart between chest wall and ribs (hand under ribs).

(*c*) If possible, take hold of the heart itself.

(*d*) Incision over heart, and pressing upon the heart itself.

(*e*) Aspirating the contents of the right ventricle.

3. Steaming hot cloths, towels, or the like over the pericardium, at the same time rectal injections of hot normal salt solution (120° F.). It may be given intravenously at the same temperature. The result is the same—a contraction of the involuntary muscles and the vessels.

4. Intra-venous injections of ammonia, 15/20 m., and four times as much H_2O every fifteen minutes, because the action of the ammonia is very fleeting, as it is destroyed in the liver. Strychnin might be used also, followed up with digitalis.

Routine treatment of respiratory Failure:

1. Mouth open and tongue pulled forward to clear the passage.
2. Head to one side of the body, a little lower than the body.
3. Artificial respiration.
4. Rhythmic contraction of the tongue.
5. Hot injections into rectum and veins.
6. Drugs.

The remedies for respiratory failure depend mainly upon:

1. Reflex stimulation of the respiratory centers.
2. Direct irritation of the respiratory tract.

Reflex stimulation of the respiratory Centers:

1. Rhythmic contraction of the tongue.

(*b*) Dashing a little ether upon the bare abdomen.

(*c*) Slapping the chest with a towel wrung out of ice-cold water.

(*d*) Stretching of the sphincter ani (the most painful procedure).

Ordinary compression of the chest is sometimes followed by an inspiration. In the larger hospitals a tank with oxygen is mostly at hand, and ready for use.

It is important to hear or feel the current of air from the nose. If this is impossible, the nose may be occluded, in which case the mouth is opened, and if this does not relieve the condition, the tongue forceps must be used. Failing of relief, a finger is placed in the larynx. If this is not successful, the patient is inverted. If all of this is unsuccessful, a sub-hyoid laryngotomy may be indicated. The trachea might now be cleaned by means of a small rubber catheter passed in through the artificial opening, and the contents withdrawn.

1505 West Ninth Street.

A Progressive College.

We are pleased to record the fact that the College of Physicians and Surgeons, of Dallas, Tex., under the able management of Dr. Arthur C. Bell, its dean, has purchased a new home for the college, and have a plot 150x150 feet, and surrounded by beautiful grounds. All the appointments will be of the latest style. We wish the college the success it merits.

Chronic Inflammation of the Pharyngeal Tonsil as a Factor in Otitis Media.

BY WILLIAM R. MURRAY, PH. B., M. D.,

Clinical Professor Rhinology and Laryngology in the University of Minnesota; Attending Surgeon Nose and Throat Department Asbury and City Hospitals; Consulting Oculist and Aurist Swedish Hospital, Etc.
Minneapolis, Minn.

It is not my intention in the brief space that has been assigned to me to refer to those well-marked cases of adenoid growths which are so prevalent during childhood, and which, fortunately, are so promptly recognized by the profession. But I refer to another class of chronic inflammations of the pharyngeal tonsil, frequently present in adults as well as in children, in which the adenoid tissue is not hypertrophied sufficiently to cause any marked obstruction to breathing, but which may be so situated latterly in the naso-pharynx as to encroach upon the orifices of the eustachian tubes, or which may be situated in the median line, and during periods of slight congestion encroach upon the eustachian tubes, thereby causing a salpingitis or an otitis media.

This form of glandular hypertrophy may be present as a result of a more marked form of adenoid obstruction which is so frequently present during childhood, or it may have existed as a chronic inflammation without having given rise to any symptoms of obstruction. The most marked symptom of which the patient will complain is a post-nasal discharge, usually accompanied by more or less hawking and spitting in the efforts to clear the throat from accumulated discharge, or an occasional feeling of fullness in the ears, accompanied by more or less deafness, due to the encroachment of the hypertrophied tonsil upon the eustachian tubes, or due to the presence of the post-nasal discharge in the region of the orifices of the tubes, which in turn gives rise to an acute, subacute or chronic catarrhal involvement of the tubes, and is extremely liable to cause a similar involvement of the middle ear, giving rise to an acute catarrhal or purulent otitis media, or middle-ear involvement may progress more insidiously, resulting in a chronic catarrhal otitis media.

As the source of involvement in middle ear and eustachian catarrh is usually due to some abnormal condition within the nose or naso-pharynx, it follows that we can hope for no permanent improvement of the aural condition until such causative factors have been removed, and in the presence of a middle ear or eustachian catarrh in which the etiological factor is the presence of a chronically inflamed pharyngeal tonsil, our efforts will be directed primarily to the removal of the hypertrophied gland, and secondarily to the correction of such changes as may have taken place within the middle ear or tubes, by such treatment, local and general, as may be indicated in each individual case.

Electric Lavage in the Treatment of Intestinal Obstruction.

BY A. P. CONDON, M. D.,

Professor of Surgery, Creighton Medical College; Surgeon to St. Joseph and Wise Memorial Hospitals.
Omaha, Neb.

I know of no condition arising in the practice of medicine in which so much depends upon the good judgment and prompt action of the physician as intestinal obstruction. He must not only be capable of appreciating the importance of the situation and the necessity of immediate interference, but he must also have the moral stamina to do a laparotomy when the indications are imperative and the life of the individual is in jeopardy.

The therapeutic measures should be confined to those which require but little time for their action; for we must keep in mind that it is the stercoremic intoxication which causes the collapse and which puts the individual in such an unfavorable state for operative procedure, and each hour of waiting lessens his chances for recovery from a laparotomy.

To my mind, the therapeutic measures to be used in acute obstruction, should be

limited to enteroclysis, the insufflation of air per rectum, and electric lavage.

Electric lavage has been much used in the hospitals of France, but has not been extensively employed in this country; it is not mentioned in our text-books on medicine or surgery.

"Electric lavage is a procedure of electrization of the intestines by means of which one tries to reinforce or to awaken the peristaltic contractions, in view of re-establishing the course of the interrupted intestinal contents, and which consists, essentially, in utilizing a quantity of water as an intestinal electrode."

I was first impressed with the advantages of this form of treatment in the clinic of Professor Boudet, of Paris, to whom is due the credit of its modern use and most of the statistics concerning the results obtained. It is not a new therapeutic agent, for even as far back as the early part of the last century we have a record of its use by Baillie, a London physician. In 1826 Leroy d'Etiolles presented to the Academy of Medicine in Paris a memoir upon the application of galvanism in the treatment of internal strangulation. Duchenne, in 1851, reported the first cure of a case of acute obstruction following the application of electricity to the intestinal canal. This, like many another medical acquirement, was not much employed and but little investigated until within the past two decades.

Physiological experiments have proved that the galvanic current is the better to employ to produce contractions of the muscular coat of the intestines. In a healthy individual, strong contractions can be caused by the faradic, but when the contractibility of the intestines has been lessened, the faradic current does not exert the same action, owing to the interruptions in the current; the effect is, therefore, fleeting and not of sufficient power to cause marked contractions, so that better and more permanent results are obtained from galvanization or an uninterrupted current.

The appliances needed for the employment of electric lavage are simple. A galvanic battery, capable of giving a milliamperage of fifty; two good conductors; one large or two small abdominal pads covered with chamois skin; a curved rectal electrode about four or five inches long enclosed in a rubber sheath to protect the mucous membrane of the rectum. It is well to have a large and small electrode, one for adults and one for children. The rectal electrode is attached to an irrigator or fountain syringe, holding from two to four quarts of warm water, containing one-half saturated solution of salt.

The rectal electrode is introduced slowly and without too much force as far as possible into the rectum. After being well inserted, the water is allowed to flow in very slowly; if injected too rapidly the rectum may contract, expelling both the water and tube. During the injection gentle abdominal massage should be applied. When a pint has been introduced the abdominal pad is placed upon the abdomen and connected to the negative pole of the battery, while the positive pole is attached to the rectal electrode.

Begin with a few milliamperes of the current and gradually increase to forty or fifty if necessary to produce active peristalsis; however, it seldom takes more than thirty. During this time the water is still flowing slowly into the bowel.

A single application should last from five to twenty minutes, according to the manner in which the patient retains it. At the end of five minutes the current can be reversed by bringing the indicator back to zero and then connecting the positive pole to the abdominal electrode and the negative to the rectal. The desire for defecation and the peristalsis may be so intense at the end of two or three minutes that one will have to desist in the operation.

The result of the injection may be a copious movement or the water may come away but slightly colored, followed by the expulsion of gas. The expulsion of gas shows that there is a permeability of the intestine, providing that it be passed in large amount and should have a foul smell, otherwise one might think that the air has been introduced with the water, which sometimes is the case.

The number of the injections to be given depends upon whether the obstruction be acute or chronic. When acute and the state of the patient is grave, after one thorough application without success, a laparotomy should at once be per-

formed. In cases of chronic occlusion, where the conditions are not imperative, after three injections, at intervals of five or six hours, with no effect, surgical intervention is indicated. The result wished for in the treatment of ileus, is the rapid restoration of the permeability of the intestinal canal. I believe that we have in electric lavage a therapeutic agent which is capable of accomplishing this end in all cases in which the obstruction is due to insufficient tone or lack of contractibility, and where by the inducing of active peristalsis the occlusion can be overcome.

Electric lavage is of much service in cases of chronic obstruction; it is of value in the obstipation that is observed in some insane, hysterics and general paralytics, and in all cases of chronic constipation.

If an occlusion has existed long and there is a possibility of gangrene or a perforation of the bowel, no time should be lost in opening the abdomen.

In every case of intestinal obstruction the first thing, if possible, is to determine its etiology, and if the cause is one that can be overcome by peristalsis, then electric lavage should be tried.

The Injection Treatment of Syphilis.

BY J. W. HANDLY, M. D.,

Professor Venereal Diseases, Vanderbilt University, Medical Department.
Nashville, Tenn.

The present day of advancement in the various departments of medicine carries with it a corresponding advancement in care and cure of that once most formidable disease, syphilis, so that now the horrors once pictured to the unfortunates of lust and passion are greatly minimized and encouragement, heretofore unknown, can be offered them with such assurance that aside from the inconvenience of the long treatment their minds are at ease.

We, as syphilologists, are anxiously awaiting the discovery of an antitoxin which will shorten the existence of the disease and probably prevent the same after a suspicious intercourse. Diphtheria and tetanus have, to a great degree, been bereft of their fatal terminations. Variola has been averted, and late literature indicates that the gonococcus serum will soon find its way into the hands of those skilled in the investigation of preventive medicine along this line. Until these serum antitoxins are perfected, we shall have to be content to use the means at hand for the cure of our patients.

One year ago I read a paper before the Tennessee State Medical Association on the treatment of syphilis, in which I outlined a most convenient treatment, per orem, by a line of quickly soluble tablets, which I have used for several years with much satisfaction, and to-day am using in many cases which can not be treated at regular intervals at my office. During the past year I have used hypodermatic medication with much satisfaction. Prior to this time I had used the soluble mercurial salts by intermuscular injection, after formulas suggested by noted syphilologists, and on account of frequent abscesses, muscular lumps and muscular soreness and stiffness aside from the pain caused by the injection, I had abandoned it. The deep injection of calomel suggested and used by these men was tried and discarded.

Since I have been using the salicylate of mercury suspended in benzoinol, after suggestions by Gottheil, my most sanguine hopes have been realized, my results most gratifying. My method of using this form of treatment does not differ materially from that laid down in the various text-books, but the success I have attained is due to closely observing the effects of the mercury, increasing or reducing or discontinuing as symptoms indicate.

A specially devised syringe without packing, glass barrel with minim marks on same one to ten and a half dozen long needles should be employed in administering the mercury suspension. The buttock must be scrubbed with soap and corrosive sublimate solution, while the needle is passed through an alcohol flame to sterilize it. The fleshy part of the buttock, at a point internal to the course of the sciatic nerve, is selected for injection. The syringe should be disconnected from

the needle to allow regurgitation in the event we have punctured a vein. To insert the oily suspension into a vein has caused syncope and other cerebral or cardiac or pulmonary disturbances. Muscular resistance to the introduction of oily mass would assure us that no vein has been entered. After withdrawal of the needle the part is sealed with collodion.

Now as to the dose. This varies from three-tenths grain to one and seven-tenths grain of the salicylate of mercury, according to the apparent needs of the patient, while the interval of treatment varies from three to seven days. It is advisable not to use the same buttock twice in succession, nor the same one if inflammatory lumps are present as the result of previous injection.

I would also suggest a rest from treatment after a period of two months, watching the case for reappearance of any symptoms. These cases frequently pick up in weight after the discontinuance of the mercury, especially when the iodide of potash is given to stimulate the glandular structures. Ptyalism is rare, yet the gums are sometimes touched by one-grain doses given at five-day intervals. I do not hesitate to commence the treatment as soon as the true chancre appears and in the cases so treated the secondary symptoms have been so light as to be almost unnoticed.

The appearance of the spirochæta pallida in the serum is sufficient evidence of the true nature of the trouble and justifies the immediate use of the antisyphilitic treatment without fear of a mistaken diagnosis. The idea of waiting for secondary lesions to appear before commencing treatment has now been abandoned. Why let the whole system become saturated with and depleted by the disease during a period of six weeks when we have positive means at hand to clear our diagnosis? At best we are delayed too long in bringing back the lost hemoglobins and diminished red-blood globules. Commence treatment as soon as possible and push it to tolerance, but not too much. Mercury in excessive doses produces similar results to that of syphilis—in moderate doses it combats the disease. Hence I reassert the closest scrutiny must be observed in arriving at a proper dose of each patient; the dose that will add flesh, strength and good color; the dose that will restore the hemoglobins and red-blood globules. I have seen mucous patches disappear from the mouth after a week's treatment with only two injections of one grain each of the salicylate of mercury. Semi-weekly doses continued prevented any return of them and general improvement to follow.

At times they complain of pain lasting a day or two after the injection. This can be accounted for by the possibility that some branch of the large nerves was punctured. It is my opinion that the injection treatment is far preferable to any other in lesions of the eye, nose or throat where active treatment is called for. Use a grain every second day until you see signs of ptyalism. Add to this increasing doses of the iodides for rapid assimilation and elimination. Brain and cord lesions can be reached by the same line of treatment, and especially in late lesions, where the iodides have relieved the gumma, will this form of mercury prevent their return.

Again, where the gastro-intestinal tract is peculiarly susceptible to disturbance by mercury or where delicate skin will not allow frequent application of the inunction or where domestic relations prevent the regular use of either, will the injection treatment come most satisfactorily to hand. By this line of treatment we are enabled to see our patients frequently, watch them closely and be able to combat quickly any symptoms that may arise. There are no nauseating solutions to upset the stomach nor no dermatitis to arise from the inunction. Patients can not dictate to themselves when they shall come to see the doctor, as is often the case in the treatment by tablets or pills, but we can dictate to them. We can keep them alive to the necessity of regular treatment, so that when all symptoms disappear they, too, will not disappear. Many of my patients prefer the injections to any other form, and feel lost without them.

Doctors, get you a syringe and get busy. You, too, will be pleased with your results.

Hot Water in Surgery.

BY HUGH WILKINSON, M. D.,

Professor of Clinical Surgery in the University of Kansas Medical College; Surgical Staff of Bethany Hospital, Kansas City, Kan.: Assistant Physician to St. Margaret's Hospital, Etc.: Kansas City, Kan.

The use of hot water in my surgical work has been so successful, or at least beneficial in so many instances, that I have chosen it as the subject of this brief article. Such a cheap, easily obtained and applied remedy needs more careful and frequent use. It is true that we are taught by many that in early inflammations cold water is equally beneficial, but I have obtained good results more frequently from the heated water thoroughly used. The cold merely relieves or prevents the congestion in the parts, and anesthetizes the nerve filaments, and is of value, if at all, only in the earliest stages of inflammation. Hot water, on the other hand, stimulates all the local human elements in the fight between the tissues and the inflammation producers. It brings more blood to the part, stimulates in place of depressing the vascular elements, and augments elimination and destruction of germs and their poisons.

In the application of hot water, great and minute care should be taken in its application. In instructing a patient about the care of an ulcer of the leg, for instance, or some chancroidal lesion, a felon, or any infection of the hand, it is a common custom to advise them to "soak the part in hot or warm water," leaving him to guess the rest. What does he do? He goes home, warms some water, and merely bathes the part, or allows it to lie a few minutes in the (probably) lukewarm fluid, and ends the procedure. No results can be accomplished from such treatment. In the instructions to his patient, he should be carefully detailed as to them. In ordinarily severe cases, I tell them to secure an ample-sized and shaped container for the part to be treated, heat a quantity of water, and submerge the part for at least fifteen or twenty minutes every three or four hours. The water should be as hot as can be borne, and when partially cooled more hot water should be added to bring it to the necessary temperature. In very severe affections, as a bad infection of the hand, or a spreading chancroid of the genitals with, perhaps, phimosis, the treatment should be repeated every hour or two.

I am aware that this is difficult to secure from many patients, especially among the lower classes, but by strongly urging them regarding its necessity we can often "scare" them into its observance.

I am speaking of hot water alone. In many of these cases the addition of some mild antiseptic seems to increase the efficiency of the treatment, especially in open infections.

The cases in which hot water, as above recommended, do good are too numerous and various to mention. In my work it has been more markedly beneficial in the class of cases mentioned above, to say nothing of sprains, old and recent contusions and swelling, and inflammation after fractures.

In gynecological work the hot douche and hot sitz bath are well-known measures, but should have a more thorough and detailed application than is commonly given them.

The use of cataplasma kaoli and its many proprietary substitutes have been greatly over-estimated as to value. Hot water as suggested here will give results time and again where the mud preparations fail.

[Written for the MEDICAL BRIEF.]

Meningitis.

BY H. M. LUFKIN, M. D.,

Professor of Clinical Medicine and Physical Diagnosis in the Homeopathic Medical College of the University of Minnesota. St. Paul, Minn.

The most common form of disease of the membranes of the brain is meningitis.

The dura mater is much less frequently affected by inflammation than is the pia mater. An inflammation of the dura mater, or pachymeningitis, as it is called,

is most frequently the result of traumatism or specific disease.

Inflammation of the pia mater, or leptomeningitis, presents the clinical variety of meningitis most commonly met with. Meningitis is so varied in its clinical manifestations that a dividing line can not be sharply drawn as to the exact location of the inflammation, the exact pathology or symptoms. For example, tubercular meningitis and simple meningitis, and even the infectious meningitis may be so closely allied in their symptoms and clinical manifestations as often to be indistinguishable one from the other, so that often we must fall back upon the etiology as the determining factor in the diagnosis. Not infrequently etiological factors may be so confusing as to render the diagnosis impossible until the late manifestations of the disease, or the necropsy. A typical case of either form of meningitis is, as a rule, not confusing, but typical cases of the text-book variety are rather the exception than the rule. The simple meningitis is so frequently a secondary affection that some authors hold that it is never idiopathic.

Non-tubercular meningitis, or simple meningitis, is either dry or exudative. This is a confusing pathological distinction, because, in some forms of tubercular meningitis we may meet with a purulent exudation.

Non-tubercular meningitis occurs at all ages, being rare during the first year of life, while the middle period of childhood is the age more commonly affected.

The most common form of non-tubercular meningitis, and that most typical, occurs as a result of trauma, or through direct extension of a local inflammation from a purulent otitis.

Some specific germ gives rise to the balance of cases met with. Of these the specific infectious diseases are the most frequent cause. These are scarlet fever, measles, erysipelas, pneumonia, typhoid fever, syphilis, and heat-stroke.

Pathology.—Pathologically two forms of non-tubercular meningitis may be distinguished. In the commoner forms the inflammation results in a general cell proliferation, resembling new connective tissue cells. It produces a dry, lusterless opaque membrane; or the inflammation may result in exudation of sero-fibrin and pus, into the meshes of the pia mater and along the walls of the blood vessels, in which case it is distinguished as the exudative form of meningitis.

The former variety is that which is seen most often clinically as complicating the acute infectious diseases.

The latter bespeaks a more serious form of inflammation, a deeper infection The exudation consists of serum, sero-fibrin or pus, and occurs in varying proportions so that the pathological designation of this form of disease would be either the serous form, the fibrinous or the purulent form, according as to which form of exudation predominates. The exudation varies from a small amount to sufficient to cause a marked compression of the convolutions of the brain.

The brain substance may show degenerative changes in the vicinity of the pathological lesion, the convex portion of the pia mater may be affected, or the base of the brain and upper portion of the spinal membranes may be involved.

The symptoms will vary according to the location, character and extent of the inflammation, as well as by the amount of the exudation present.

Symptoms.—As meningitis is commonly secondary to injury, or some other disease, its symptoms and course may be obscured by the special disease of which it is a complication. We see, occasionally, a child come down with active cerebral inflammation without apparent cause. The disease runs a rapid course, proving fatal in one or two to eight days. A careful search, however, will reveal some cause for the meningitis, which clearly removes it from the so-called idiopathic class. The symptoms do not vary, excepting in the acuteness of the attack, in apparent idiopathic cases, from those which can be distinctly traced to a primary cause.

As this disease is one which generally affects children, it is often impossible to gather etiological factors, such as falls, earache, a co-incident pneumonia, or any one of many causes which may appear simultaneously with the meningitis, and yet remain undiscovered.

The following case is one of the apparently idiopathic variety. A child, three years of age, showed in the morning some

indisposition, loss of appetite; was observed to hold the hands to his head as if suffering from headache. A slight rise of temperature caused the family to attribute the trouble to indigestion. Within a few hours the symptoms developed rapidly when the following condition presented: Flushed face, somnolence, twitching of the muscles of the arms and feet, rigidity of the neck, and repeated convulsions.

The temperature the first day did not exceed one hundred and two degrees; the second day temperature one hundred and three degrees; convulsions more frequent, consisting of tonic and clonic contractions of the muscles of the face and extremities, with marked retraction of the head. Beginning of third day there was a convulsive seizure lasting over a period of two hours, at which time I saw the case in consultation, when a temperature reaching the limit of the thermometer (one hundred and eight degrees), was noted. The child was unconscious; almost pulseless; face cyanotic. Cold baths reduced the temperature rapidly; convulsions subsided, and the child returned to consciousness for two or three hours, when increasing somnolence recurred, with repeated twitchings, final recurrence of uncontrollable convulsions and death.

Careful inquiry disclosed no possible cause for this attack of meningitis, yet, in all probability, the child, without the knowledge of his parents, had suffered some slight injury to the head.

The most notable feature of this case, aside from the source of the infection, was the remarkable high temperature, with subsidence of the convulsions, and return to consciousness.

Of the milder types the following will serve as an illustration. It represents the pathological lesion in the class case of acute non-tubercular meningitis: A baby six months old, had suffered several days from looseness of the bowels, characterized by stools green in color, containing curds and mucus. Some loss of appetite, and marked rise of temperature. On the third day temperature rose to one hundred and three; child became fretful and irritable. A general hyperesthesia developed so that it was impossible to touch or move the child without causing great pain and discomfort. It was found that light was objectionable, and movements of the head caused great pain. The bowel condition throughout the course of the disease was typical of a mild summer diarrhea, varying little from day to day. The fourth day, after a comfortable night, considerable edema of the face, hands and feet was noted. On the fifth day the temperature rose to one hundred and five degrees, retraction of the head became marked; some contractures of the feet were noted, reflexes all exaggerated; converging strabismus developed; a stroke of the pencil upon the abdomen produced a red, congested line (*tache cerebrale*) lasting five to seven minutes before fading. Food was refused. The next day temperature dropped to normal; stools less frequent; child noticed things for the first time without irritability. Cried, and could stand some light. Sixth, seventh and eighth day completed convalescence.

The mother of this child had had two pulmonary hemorrhages within the month; had tubercular deposits, abscesses of both lungs; was nursing the baby. The history of the mother led to grave apprehension of tubercular meningitis, although tubercular meningitis is rare during the first year of life.

The following case illustrates simple meningitis, following injury to the head, with deferred active inflammation: Child three years old. Mother a sufferer from Graves disease in advanced stage. (She died within the year of the baby's illness.) No tubercular history. Baby playing as usual, when she fell, striking her head; was very pale, and suffered some shock, and vomited once or twice, but was soon as well as ever. A week later the mother noted a vacant stare, lasting but a second, after which the baby became sleepy. A short nap seemed refreshing, only these attacks became more frequent, several occurring each day; each was followed by drowsiness. No rise of temperature, yet there developed unusual constipation and irritability. During the following month the child failed in nutrition; became gradually more irritable; shunned bright light, and slept poorly. The seizures, which were hardly noticeable at first, had become more pronounced and frequent; the eyes turned; one hand and arm became flexed

and rigid. The seizures would last two minutes, and were followed by stupor lasting an hour. The absence of fever and the transient character of the symptoms led to a diagnosis of epilepsy, the result of injury. Six weeks following the first attack the patient was seized with a general convulsion, lasting half an hour, followed by fever. The symptoms before noted as being only transient in association with the seizures now became permanent. There was marked rigidity and retraction of the neck, strabismus, photophobia, anorexia, marked *tache cerebrale*, reflexes all exaggerated; repeated convulsions, a gradually ascending temperature, rapid wasting, and death in ten days. Paralysis of the extremities of the left side indicated cerebral pressure. There was no autopsy, but this was evidently a meningitis of the exudative type.

As a noticeable contrast to this class of cases, I cite the following, which is fairly typical of the tubercular type:

Miss M., a young girl in her first year at high school; mother died of tuberculosis of the lungs soon after the child was born. The father was in good health, without tubercular history in his family. This girl is an only child. She had a sunny, sweet disposition, and is beloved by all who know her. She has never been well and strong. Caught cold easily, suffered with attacks of vertigo, etc.; had not been able to attend school regularly, but was in advance of children of her age, because of unusual precocity. She had the usual diseases of childhood, but always made an apparently good recovery. During the spring of 1905, while attending school she complained of being easily fatigued, then complained of headache. This condition was attributed by her parents to eye-strain. It was after this that her stepmother called at my office and called my attention to the condition which seemed to have existed for several weeks, until she had become somewhat worried. A prescription was given, with instructions to keep careful watch. The history of the case, the tuberculosis of the mother, and my knowledge of the child's general malnutrition, led to a suspicion of a beginning meningeal trouble. Two weeks later the mother returned, saying that the headaches had become unbearable, but yet did not wish me to see the child, as she thought that a rest from school would clear up the trouble. The following week I was called to see the child, and found her in bed suffering intensely from headache. Her face was flushed; eyes sensitive to light. She complained of pain in her limbs, inability to sleep, and a general hyperesthesia of all the senses. Her disposition, which had previously been of the mildest and most docile type, had changed to one of irritability. Yet the patient realized this, and after some sharp command, would apologize, and fall into tears for being so ungrateful and unappreciative of the attentions paid her. The following week there was slight change in the condition. Headaches failed to respond to treatment. Irritability increased. The skin, which was always pale, seemed waxen in color. A slight touch of the finger was usually followed by a red blush of congestion, which would last for several minutes. The reflexes now became exaggerated. This condition continued for another week without material change, while the headache persisted. The irritability would show periods of amelioration, and some sleep would be obtained; then again wakefulness, alternating with slight delirium. She could take no food, and when she did, especially liquid food, it was soon ejected with great force, without premature nausea. About this time marked rigidity of the neck developed, and it became impossible to move the patient in any way without causing incomparable agony. During the short time the patient slept there was more or less delirium of a passive type, followed by periods when she was rational. The pupils, up to this time, had remained normal; reacting to light, but now became irregular in outline, and one contracted more than the other. Slight twitchings, followed by contraction and rigidity of the feet and hands developed. The pulse, which, during the first part of the illness, was somewhat accelerated, one hundred and five to one hundred and fifteen, during the third week of the disease, became very much slower, and gradually developed irregularity and weakness. Unconsciousness supervened in the third week of the disease.

A period of amelioration took place about this time, when the patient became rational, talked freely to her parents, seemed to appreciate the gravity of her condition, met and talked with friends, predicted her possible death, and made some bequests. This period of apparent amelioration was followed shortly by complete unconsciousness and the development of the Cheyne-Stokes respiration; several convulsions of a mild type supervened, and the fourth week of the disease the patient died apparently from exhaustion.

A diagnosis of tubercular meningitis was made at autopsy. There was some slight dullness in upper lobe of lung.

In the main these cases present typical examples of their type, while some depart from the same. This case of tubercular meningitis is rather advanced in age, between three and ten years being the usual age in which we find this disease. To differentiate the various types of meningitis is often impossible. It is almost impossible to say before autopsy that a meningitis is of the purulent, exudative or tubercular purulent variety. Yet there are features of distinction which, with patience, and a careful analysis of the symptoms, will aid in diagnosis. The distinguishing points between non-tubercular and tubercular meningitis are: first, the etiology. Tubercular disease in some member of the family, or a distinct exposure to tubercular infection, the presence of tubercular glands or a tubercular deposit, or non-tubercular disease in the subject before the onset of the tuberculosis should be looked for. The non-tubercular variety presents an acute onset, and a generally rapid course; the pulse is rapid from the start, increasing in rapidity with early falling of the pulse. The respiration in the tubercular variety, is slow, very irregular in type, and develops the Cheyne-Stokes respiration later than the non-tubercular variety, in which we have rapid respiratory movements. The convulsive seizures in the tubercular variety are less marked, are slight in their manifestations, less general, as a rule, and appear later in the disease. Hyperesthesia of all the senses is variable, depending largely upon the amount of exudation present. While these differential points apply to many cases, the order of the development of the various symptoms may be such as to leave one in doubt for some time before a just estimate of their importance can be determined. Especially is this so in the non-tubercular variety, which has been preceded, or is accompanied by some infectious type of disease which it complicates. The meningitis being so altered by the symptoms of the primary infection as to render the diagnosis confusing. Tubercular meningitis is admittedly invariably fatal. Simple meningitis presents an unfavorable diagnosis in the majority of cases, yet we see many cases recover, often with permanent disability from local paralysis or degeneration of the brain substance, leaving the child a defective for life.

The treatment of either variety is purely symptomatic. Absolute quiet and rest should be secured and freedom from all sources of irritation. To accomplish this a trained nurse who thoroughly understands the requirements of the case is invaluable.

The type of remedy used in treatment is that which expends its main action upon the functions of the brain. Belladonna in the third attenuation, and aconite meet the early symptoms of congestion and cerebral excitement. Later, when delirium develops, stramonium is useful. The extreme irritability and early development of these cases, accompanied by constipation and vomiting, will often call for the use of nux vomica or bryonia. For the high temperature, cold baths and the ice cap are indispensable. The treatment after convalescence should be as carefully adjusted as during the onset of the disease; it sometimes requires months to restore the patient to a normal state of nutrition and nerve balance.

While the prognosis is always grave, it is never safe to predict a fatal issue, particularly is this so with young children, as their unstable nervous organisms are such that a slight irritation or a moderate dry meningitis may closely resemble a more serious type, and yet perfect recovery takes place.

[Written for the MEDICAL BRIEF.]

Recto-Colonic Feeding.

BY CHARLES J. DRUECK, M. D.,
Proctologist to People's Hospital.
Chicago, Ill.

In presenting this paper I wish to state that I am not so enthusiastic as to suggest this method of alimentation as a substitute for the normal avenue of ingestion, but in the treatment of certain conditions it may be desirable, if not imperative, to relieve the stomach of all food for a time, and in these cases we may temporarily sustain the patient by introducing foods into the rectum and colon through the anus. It has long been recognized that all mucous membranes will absorb certain substances and pass them into the lymphatics, but only recently has this knowledge been applied to rectal feeding. Kelsey cites numerous authors who speak of the relative absorbing power of the colonic and gastric mucous membranes and a considerable proportion of them conclude with some such evasive statement as: "It is not wholly established yet, that sufficient nourishment may be absorbed by the mucosa of the rectum and sigmoid to sustain life." Bauer, for instance, states: "Not more than one-fourth of the necessary nutriment even under the best conditions can be absorbed from the rectum."

Such statements in the light of our present knowledge must be modified, because enemata must not be deposited in the rectum or sigmoid, and moreover experience has shown that many patients not only live but some even gain slightly in weight when the injections are carefully given according to the directions that appear later in this article. Thompson (*Practical Dietetics*) supported a patient seven weeks, and Flint (*N. Y. Med. Rec.*) refers to a patient who was nourished for fifteen months by rectal feeding alone and who had been maintained chiefly by this method for five years. These, of course, are extreme cases, but it is safe to state that any patient may be maintained for three or four weeks upon this artificial feeding exclusively, and this is sufficient to produce the desired results or tide the case over a crisis in many instances. Friedenwald and Ruhrah, in their book, state that an individual may be sustained four to seven weeks. It will be easily seen that the writers of fifteen years ago and to-day differ materially in their opinions as to what may be accomplished.

Feeding by way of the rectum has been objected to mainly on theoretical grounds of physiology, although I might add that in my experience the method of administration is often faulty. The rectum proper, that is the last six inches of the bowel, has very limited absorbing power, but Landois has shown that the colon has very marked assimilative power, although the digestive ferments are feeble. Thus properly prepared foods are readily absorbed and considerable nourishment thus derived.

Recognizing the fact that patients are nourished by foods administered per rectum and still maintaining that the secretions of the rectum have little digestive power, very peculiar theories have been advanced as to how assimilation is accomplished. Flint (Trans. N. Y. Acad. of Med.) says. when food comes in contact with the rectum while the stomach is empty, the gastric and intestinal juices descend to the rectum. Batty, by experiments on cadavers, concludes that the injected food ascends the whole digestive canal instead of remaining in the colon or rectum. He thus accounts for the phenomenon of patients being able to taste substances such as quinine or castor oil when given per rectum. C. W. Brown, of Washington (Food, Vol. 4, No. 8), cites a case where the patient was able to distinguish the taste of potassium iodide or ergot fifteen or thirty minutes after they were given per rectum, and accounts for it by rapid absorption and transmission through the blood to the taste bulbs and saliva. Voit and Bauer were the first to find that sodium chloride added to meat juice and peptones greatly increased their absorbability when used in enematas, but the salt stimulates reverse peristalsis to such an extent that many writers (Grützner and later Swiezuski) have been able to demonstrate in the stomach substances that had been administered per rectum.

INDICATIONS FOR RECTO COLONIC FEEDING.

1. Obstruction to the entrance of food into the alimentary canal, as by new growths, foreign bodies, inflammatory swellings of the mouth, pharynx or esophagus which may result from disease, corrosive poisons like carbolic acid, ammonia, or following operations upon these parts.

2. Inability to swallow food as during coma, delirium, post-diphtheric paralysis or in the presence of spasmodic conditions of the esophagus, also during acute insanity when food is refused by the mouth.

3. Gastric disturbances, such as acute gastritis, hyperchlorhydria, hypersecretion, gastric dilatation, ulcer or cancer when it may be desired to rest the stomach, also the reflex vomiting of pregnancy or seasickness.

4. Stricture of the lower digestive tract, but above the cecum.

5. Feeble digestion and when emaciation is increasing.

PRINCIPLES OF RECTO COLONIC FEEDING.

The minutest details are important and the enemata should always be given by the physician himself instead of intrusting it to a nurse, because the patient's life often depends on the treatment being carried out for some time. If the rectum becomes irritated, it usually means the suspension of the treatment, because only rarely can the feedings be withheld long enough to quiet the local trouble. Occasionally a patient will object to the feeding for esthetic reasons and the physician must use tact and persuasion. Before taking up the details of methods I desire to emphasize the following as being vital to the success of the treatment:

1. The rectum must be free from mucus or feces before giving the enema.

2. Any irritability of the rectum is to be relieved as quickly as possible.

3. The quantity and quality of food used should be carefully regulated to avoid peristalsis and to allow complete absorption of one injection before another is given.

ADMINISTRATION OF THE INJECTION.

The utmost care is necessary in the manipulations because irritation or injury to the rectum is inevitable if careless, rough or unskilled attempts are made. The exact condition of the rectum must be determined and explicit, written instructions given, when a nurse is intrusted with the work because failure often results from leaving this matter to persons ignorant of the anatomy and physiology of the parts and of the conditions that may arise or are to be observed.

At first the clysters may be rejected, but when properly prepared and administered the rectum in many instances soon acquires a tolerance and the nutrient enemata may be given in sufficient numbers and volume to support the patient for weeks. In all cases, proctitis is likely to arise and it is only a few favorable instances that irritation and diarrhea does not occur after several weeks. When this does happen the enemata must be stopped temporarily to be resumed after the bowel improves. All local troubles like ulceration, fissure, fistula and especially hemorrhoids are drawbacks. Great care must be maintained not to irritate the latter by rough usage of the catheter or syringe nozzle. The use of a soft, flexible catheter and a two per cent cocaine solution is imperative for such cases. I will mention the ordinary syringe with the short nozzle only to condemn it. For children, a number twelve or fourteen "velvet-eyed," flexible catheter may be used, but for adults, a full length rectal tube about one-half inch in diameter should be selected. The tube should be rigid enough to free itself and not bend or double, if it catches in a fold of mucous membrane, and yet must not be stiff enough to cause pain or damage when introduced. Sweet oil, butter or vaseline may be used as a lubricant, but not glycerin, as that excites peristalsis.

One of the first essentials for absorption by the colon is cleanliness within the bowel. It is very evident that if the colon or sigmoid are filled with feces or the membrane covered with mucus it is impossible for osmosis to occur. Therefore, before any nutrient is introduced the colon must be thoroughly emptied and cleansed. One hour before the time of giving the morning feeding the colon should be flushed with a high injection of one quart of normal salt solution, a return flow catheter being provided that the water may find easy exit and thus avoid

stimulating peristalsis. In many instances one such cleansing each day will be sufficient, but if much mucus is present it is well to precede each feeding with the cleansing injection, and in such cases the salt should be replaced by two teaspoonfuls of sodium bicarbonate. When the rectum is tender or inflamed a saturated solution of boric acid is best borne. This procedure washes out any undigested food or waste matter, cleanses the mucous membrane, stimulates the local circulation and thus provides better absorption.

The temperature of the solution used to flush the bowel is a matter of some difference of opinion. Tuttle recommends cold water because he finds tnat it acts more promptly and leaves the bowel more tolerant of the succeeding nutrient enema. My own preference, however, is for solutions nearly the body heat, as they cause less reaction, in other words, congestion of the mucosa. The nutrient enema being kept in contact with the tissues for a considerable time must necessarily induce some reaction, and if we, by any treatment, over-stimulate and thus irritate the colon, it promptly expels the whole contents and thus may unfavorably determine our case.

A very important point is to flush out the bowel some little time before giving the nutrient (in my practice I make this about one hour) and then allow the patient absolute rest in bed. A fountain syringe or an ordinary stomach tube and funnel may be used to fill the rectal tube. The apparatus must be tried before introducing to see that all is in working order. It is well to heat the appliances to about 100° F. to prevent chilling the enema before it is injected; fluids either too hot or too cold are promptly expelled. An enema at 90° to 95° F. is best retained. When everything is ready the tube is filled with the enema before introducing, to insure the exclusion of air, because air is very likely to stimulate peristalsis and evacuation.

The tube is introduced with a twisting or boring motion to avoid its becoming impacted in the folds of the mucous membrane. If it meets resistance, a little of the fluid is admitted and the rectum dilated or ballooned. After the tube has passed the sphincter (about four inches) it is allowed to rest a few minutes until the temporary excitement has subsided and during this rest any colonic gas that is present is frequently expelled. The tube is then advanced as high as possible to bring the fluid in contact with a large amount of mucous membrane and to lessen the tendency toward ejection. Some authors lay considerable stress on the anatomical arrangement of the circulation. The blood returned from the colon, sigmoid and superior hemorrhoidal veins enters the portal system, while that from the lower rectum, the inferior hemorrhoidal veins, enters the vena cava, so that substances absorbed by these latter veins do not go through the liver, but substances absorbed higher up pass through the vena porta to the liver and are there further elaborated. Be that as it may, the fact remains, that sugars introduced into the rectum do not cause glycosuria because the rectum has very little, if any, absorbing power and the food must pass up into the colon to be absorbed.

After the tube has been fully introduced the injection is allowed to run out very slowly, occupying fifteen minutes or more because rapid injection stimulates peristalsis. The bag should be held about two feet above the level of the patient's hips.

When the tube is nearly emptied and before any air has a chance to rush in after the injection, it is firmly compressed and slowly but steadily withdrawn. Then to aid retention, a soft, folded towel should be firmly pressed against the anus for twenty or thirty minutes. This reduces the temporary excitement and the tendency to evacuation. The patient should remain quiet for at least an hour and be instructed to try to retain the injection. Cheerful conversation by the doctor or attendant diverts the patient's mind and is of much assistance where there is a fear of expulsion.

POSITION OF PATIENT.

The position of the patient also assists, the left lateral prone with the hips raised on a pillow is usually sufficient, although if the patient is nervous or hysterical, it is well to use the knee-chest position. In gynecological or obstetrical cases where enemata are given, it must be remembered that tight vaginal tamponing interferes with absorption from the rectum.

The number of injections per diem depends on the irritability of the rectum and at the beginning should be one in eight or twelve hours. If after a couple of days the rectum is in good condition and it is necessary to give small enemata frequently, they may be repeated every six hours. However, frequent clysters usually irritate the rectum and have to be suspended soon.

OPIUM IN ENEMATA.

Opium in the form of laudanum (from three to twenty minims) may be added to the nutrient when irritation exists, but it must be remembered that though opium inhibits peristalsis and thus favors retention of the enema it also interferes with its absorption. Whenever it is given, its doses must be guarded and its action watched. If the nutrient enemata have been continued until the rectum is irritated, the opiate often acts better when injected into the rectum one-half to one hour before the enema. When administered in this way, the volume is so small that it acts locally before the larger, nutrient enema is given. The deodorized tincture of opium may be used instead of laudanum.

The presence of hemorrhoids is one of the most unfavorable handicaps to the treatment because they are so easily irritated and inflamed and thus set up spasmodic contractions of the sphincter. If they exist, they should be carefully painted with a two per cent solution of cocaine muriate just before each feeding and immediately after a mild astringent and sedative ointment should be used.

FOODSTUFFS USED IN RECTAL FEEDING.

Not all substances administered by mouth are available for colonic feeding. It is important to use only such substances for colonic foods as will be almost, if not wholly, absorbed, because all residue acts as foreign matter. It has been found that many albuminous foods, although absorbable, become irritants when given in too great a degree of concentration. Pure peptones, for example, must be diluted with two or three volumes of water or some bland vehicle. Some albumens, such as egg or that of chopped meat, may be absorbed by the colon undigested, but even these are better when partially pancreatized. Albumen is very slowly, if at all, diffusible, and must be previously changed into albumose. This may be accomplished easily by adding pepsin or pancreatic extract to the injection, either some time before administration, thus allowing digestion to take place outside the body, or mixing the digestive in the clyster just before giving it and allowing digestion to proceed within the bowel. Catillon, experimenting along this line on dogs, noted that the animal fed on unaltered egg lost weight and barely existed, while the one receiving eggs mixed with pepsin retained normal weight and apparent health. After thirty-seven days the pepsin was removed and the animal gradually lost weight. Plain starches are poorly absorbed from the rectum, but when partially converted into grape sugar are absorbed more readily.

FATS.

In the selection of a food for artificial feeding the caloric units which it contains is obviously important and it would appear, therefore, that fats and oils would be pre-eminent, yet clinically it is found that fats are not only not absorbed, but, when administered they tend to coat the mucosa and the food and thereby prevent absorption. This is most unfortunate because a given amount of fat produces twice the energy that the same amount of proteid or carbohydrate food does. Attempts have been made to saponify the fats before their administration and Edsall and Miller (of Philadelphia) have carried out some extensive experiments along this line, but were unable to find a soap that was soluble that did not contain so much from alkali as to make it markedly irritating to the bowel. The only other way of giving fats is in emulsions, but in using plain milk and yolk of egg it is found that the proteids entangle the fats in the coagulum and stop digestion. With artificial emulsions and with malted, peptonized or pancreatized milk much better results have been obtained. The advantage in these preparations is that the fat is very finely divided, and in such condition much more fat is absorbed than is usually credited. About one-half ounce of the powder mixed in five ounces of

saline solution is the average amount and is well absorbed without irritating the bowel. In the ordinary course of digestion, administering food by mouth, the fats are absorbed wholly by the villi of the small intestine and very little action normally takes place in the large bowel on fats.

EGGS.

Egg albumen is one of the best, if not the best, ingredient for rectal feeding and is absorbed even though unchanged when administered, but is better acted upon if predigested with peptogenic or pancreatic powder. Ewald says egg albumen unpeptonized is absorbed as readily as commercial peptone, while peptonized egg albumen is taken up with even greater facility. The addition of fifteen grains of table salt to each injection aids the absorptive power, though where the salt is used we occasionaly set up a reverse peristalsis. I wish to call your attention to what I have previously said, that in some cases we have sufficient retro-peristalsis to carry the food into the small bowel, and it is in these cases, I believe, where we have such happy results, in that the patient not only holds his own, but seems to improve in strength. The yolk of the egg is not used, because it contains so much fat mixed with the albumin as to be useless.

PANCREATIZED MEAT.

Pancreatic extract of some form may be used in preparing proteid food, but must be fresh, because it does not keep long, and if old may act as an irritant. Glycerin extracts of pancreas can not be used on account of the aperient action of the glycerin. Leube suggests the addition of one part fresh pancreas to three parts of fresh beef, as the best method. The pancreas and meat are finely minced and rubbed together into a paste with the addition of a little water. All fat must be carefully removed. Mayet suggests practically the same formula, but with the addition of one egg, and adds: "Mix and let stand two hours before administering." It is occasionally recommended to add Hcl. to beef solution and also to milk, but the acid is too irritating and all such artificial digestion must be carried on outside the body.

BLOOD.

Dried beef blood has been used as a rectal food, but is not practicable, for it usually clots within the rectum and prevents the absorption of other substances. Fresh, defibrinated blood has been used, but is not popular or satisfactory.

GLUCOSE.

Glucose is absorbed if diluted. If given in concentration it irritates the mucosa and stimulates expulsive peristalsis. Leube recommends three hundred cubic centimeters of a fifteen per cent solution as a maximum.

STIMULANTS.

I will call your attention to but two stimulants, namely, coffee and alcohol. There are times, especially in the immediate post-operative treatment, when it is desired to combat shock even more urgently than to give nourishment. A pint of good coffee (black) contains five to seven grains of caffeine and gives prompt and effective support. Whenever the stimulant is desired the pint of coffee may be substituted for the ordinary nutrient enema, and in this way may be used more liberally than alcohol because it is not so irritating; although, of course, all stimulants are really irritants and in protracted cases their frequent use renders the colon intolerant.

Alcohol in fifteen per cent dilution of good liquor stimulates the bowel and increases the absorbability of the proteids. One of the strong points in the use of liquid peptones, as they are offered in the market, is that they contain about that strength of alcohol, together with about eighteen per cent of carbohydrates and proteids. When added separately to the enema about one drachm of brandy or an ounce of red wine is enough. The Europeans prefer red wine because of its astringency. The alcohol should be added after digestion is completed in the mixture and just before its administration. Larger amounts of liquor are likely to irritate the bowel. Very often a small injection of one-half ounce of whisky, sherry or brandy in one and one-half ounces of water will be retained and absorbed, when larger quantities of fluid with the alcohol incorporated are expelled. Undiluted whisky added to milk some-

times causes a precipitate by coagulating the casein that is not pancreatized, and as no solid matter in even a fine precipitate is any use in the colon it simply acts as an irritant.

FORMULAE OF NUTRIENT ENEMA.

Having considered somewhat the kinds of foods that are applicable for artificial feeding, we must next combine them to suit our various needs because no one food will sustain life wholly, and the nutrient enema must combine proteid, carbohydrate and salt. I have had good success by using an injection of peptonized milk eight ounces, whites of three eggs and one-half teaspoonful of table salt for one feeding, and at the next injection using pancreatized meat eight ounces. About once every other day it is well to add two ounces of grape sugar to one feeding for its heat energy. By alternating these foods my patient receives all classes of foods in a readily absorbable form. In emergency cases, where we can not prepare these foods for each feeding, we may use one of the commercial beef peptone preparations in the proportion of one to two ounces of peptone solution and four ounces normal salt. Where these alcoholic mixtures are found to be too irritating, better results will be obtained by substituting malted milk, one ounce, and saline solution, five ounces. The formula of Ewald gives very good results where one recipe is to be used; it is: Beat the whites of two eggs with a tablespoonful of cold water, add one or two teaspoonfuls of boiled starch in one-half teacupful of twenty per cent glucose solution, a wineglassful of claret and a teaspoonful of peptone solution. Mix at a temperature below the coagulating point of the albumen.

The amount of nutrient injected each time must be determined in each case. Some patients can retain but three or four ounces. In such cases the clysters must be given more frequently, perhaps every four to six hours, while others will comfortably retain up to eight ounces and need not be fed oftener than every eight or twelve hours. When the enemata are given frequently it is always necessary to add some opiate, as the rectum is sure to become sensitive. In nearly all cases we must add opium after a week, and as the doses need frequently to be increased, it is well to begin with a small dose.

A large part of the success in this work depends upon familiarity with the method employed. I do not want to be misunderstood as implying that rectocolonic feeding can entirely replace the natural method of assimilation, but I do insist that in the proper class of cases, where a few days to four weeks may mean the saving of a life, this way of feeding will sustain the patient and in some instances even add to his weight. Hunger and thirst are often very annoying for a few days, but after that the patients are relatively comfortable, the tongue remains clean and moist, and the longings diminish.

I will call your attention to just one case. Mrs. B., aged thirty-five years, a Bohemian, housewife, was referred to me with a desperate case of gastric ulcer. Her pain was almost constant and even liquid foods caused agony and usually vomiting. She had lost so much strength that she had to be carried to the hospital. A sharp hemorrhage had existed the day before, but had practically subsided when I saw her. I deferred operation in her exhausted condition, and to relieve her urgent symptoms advised colonic alimentation. From the time I saw her she took nothing by mouth for one week and for the next three weeks that the treatment was continued only water was allowed. All nourishment was given per rectum. The first enema was a pint of strong black coffee and after that peptonized milk and egg alternated with pancreatized meat. Once every other day I added a little coffee or alcohol. The first day this woman begged for something to eat or drink, but after the second enema the pulse was perceptibly fuller and her cravings moderated. She was thirsty the whole first week, but when water was allowed I found that one pint per day kept her very comfortable. She had one hemorrhage on the third day of the treatment, but none after that. Her pain gradually subsided and when she was finally allowed a restricted diet she was in much better physical condition than when she entered the hospital, and even expressed a willingness to continue with

the enemata if I thought best. Several months later this patient returned of her own accord and said she was having some of the old pain and asked for further treatment. The gnawing pain disappeared in thirty-six hours, but the stomach was kept at rest for a week. The patient was seen again during the preparation of this article and says she has no symptoms of the old trouble. I report this case because it is not an extraordinary one, but on the contrary, is such as most of us meet very frequently and where the indications are clearly to put the stomach at rest.

[Written for the MEDICAL BRIEF.]

A Case of Gangrene of the Foot Following Diabetes Mellitus and Arterio-Sclerosis.

BY FRANK WARNER, M. D.,

Professor of Operative and Clinical Surgery in the Starling Medical College.
Columbus, Ohio.

Recently I was called to see a case of gangrene of the foot in consultation with Dr. Clement, of Groveport, Ohio. The patient, a man sixty-three years of age, had been a farmer for many years, and had led a temperate and active life. Family and personal history good. Some years before he developed diabetes mellitus, from which he has been suffering. An examination of the urine showed five per cent of sugar; specific gravity, 1036.

Blood examination showed hemoglobin, eighty per cent; red corpuscles, four million five hundred and sixty thousand; white corpuscles, six thousand five hundred. The differentiation count of whites showed normal. The red corpuscles were well formed, barring occasional slight irregularities in conformation.

The gangrene involving the foot was of the moist variety. Two toes were black, and a discoloration extended along the plantar surface of the foot, half way from the toes to the heel. The foot itself was somewhat edematous, this edema extending even above the ankle.

It was seen at once that amputation was imperative, but whether to undertake this operation immediately with the high percentage of sugar in the urine, or to delay it until the percentage of sugar could be diminished, was a problem to be decided.

Another important question to be settled in my mind, when amputation should be done, was whether we should be content with sacrificing the foot alone, or, under the presumption that this gangrene was dependent upon a great amount of impingement of the arterial supply of blood to the foot—presuming that this arterial sclerosis resulted in a compromise of the caliber of the vessels up to the point of their distribution from the popliteal artery—making amputation at or above the knee necessary.

The operation was delayed one week and the patient was put upon a non-saccharine and non-starchy diet. Analysis of the urine, at the end of one week, showed that the sugar had been reduced to four per cent.

Amputation was now made above the knee. The patient bore the operation well, and there was but little shock. The wound healed promptly.

The point in this case of great interest to me is that an examination of the leg, subsequent to operation, showed the arterial vessels below the knee to have been almost completely occluded, and that an amputation anywhere short of the point at which it was made could have resulted in but absolute failure.

The literature upon this subject shows that this is usually the case, and that when an amputation is made necessary by a similar state of affairs, arising in the course of such a case, a high amputation, such as we made, is imperatively demanded. Still, in the face of all this literature advising high operation in this class of cases, we are constantly seeing low operations, simply removing the foot at the ankle, and the amputation made just above this point. And when this is done, we are accustomed to see almost constant failures as a result.

10 West Goodale Street.

Inclosed find M. O. for one dollar, for which send me the BRIEF for another year. I love it better than any other of my journals.—J. E. Cox, M. D., Boughton, Ark.

Diseases of the Breast.

BY ALFRED DE ROULET, B. S., M. D.,
Chicago, Ill.
Formerly Professor of Surgery and Diseases of Women in the Medical Department of Trinity University.

V.—CANCER.

While we know practically nothing of the etiology of cancer of the breast, there are certain facts in the clinical history of each case which stand out with more or less prominence, and to which a considerable degree of importance should be attached.

The age of the patient is a factor of considerable importance, cancer of the breast being most prevalent in women of from forty to sixty years of age, seventy-five per cent of all cases occurring during this period. The condition is very rare in young women, and is practically unknown before puberty. The cases reported from time to time as occurring in very young children are, in most cases, I am inclined to believe, sarcomata, rather than carcinomata. Gross, in his study of sixteen hundred and twenty-two cases, finds that the average age at which cancer appears in the breast is forty-eight years, the earliest time of onset in this series being in the twenty-first year. Williams reports a series of five hundred cases, in which the youngest patient was twenty-four when the growth was discovered. In extreme old age cancer of the breast is comparatively infrequent, but whether this is due to a prevailing scarcity of extremely old people or to a lessened susceptibility, I am as yet unable to express an opinion.

Traumatism has long been considered an important etiological factor, but, on investigation, the data on which this belief is based is far from convincing. For example, if trauma was an efficient cause of cancer we would naturally expect to find the new growth developing in the portion of the breast most exposed to injury, as pressure or chafing from an ill-fitting corset, or from the injuries incident to nursing. As a matter of fact, cancer appears most frequently in the upper outer quadrant, which is the least exposed to injury of any portion of the breast, while the nipple and areola, which is the region most exposed, is almost immune. Gross was able to elicit a history of injury in one hundred and ninety-six cases out of one thousand five hundred and eleven cases examined; Winiwarter, with one hundred and seventy cases, found previous injury in twelve. Williams questioned one hundred and thirty-seven patients with a view to eliciting a history of previous injury and was successful in thirty-five cases, and of these thirty-five he says: "Many of the above affirmations appeared to me to be the outcome of imagination, rather than proving any real causal relationship, and in no case was there evidence that the disease had developed out of induration or other obvious lesion thus induced."

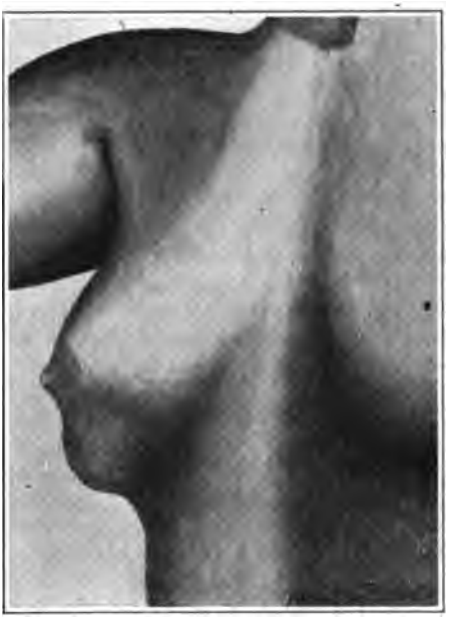

FIG. 1. Unusual Location of Nodule in Cancer of Breast, Tumor Appearing Below Nipple.

While it is undoubtedly true that cancer is not infrequently discovered at the time or shortly after the receipt of a blow or other injury, I am convinced that the injury has nothing to do with causing the cancer, although it may call attention to an already existing, but unsuspected, condition.

Lactation and chronic mastitis are considered by many to be important factors in the causation of breast cancer, but, as

in the case of trauma, the evidence is not sufficient to afford positive proof. In reviewing the histories of seven hundred and sixty-five cases reported by different authors, I find that of this number five hundred and twelve have nursed one or

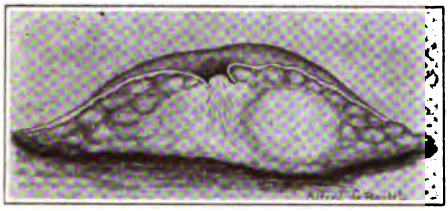

FIG. 2. Section Showing Gross Appearance of Carcinoma of Breast. Nipple Drawn Backward and Toward Tumor.

more children, while two hundred and fifty-three were either sterile or their breasts had never been functionally active. Until the fact is established that barren women are more than one-third as numerous as their more prolific sisters, we have no reason to believe that the normal activity of the mammary gland in any way predisposes to cancer.

Heredity is frequently mentioned as a cause of cancer, and in this instance I believe the evidence is sufficient to at least justify the conclusion that cancer or a predisposition to cancer may be hereditary. The frequency with which cancer appears in certain organs in several members of the same family or in several generations of the same family, is at least suggestive. For example, in the Bonaparte family, Napoleon I, his father, one brother, and two sisters died of cancer of the stomach. Senn says that he has repeatedly seen cancer of the breast in two succeeding generations. Sibley relates an instance of cancer of the left breast occurring in a woman and her five daughters. Broca has reported by far the most complete, as well as the most convincing case of this kind. Mme. Z. died of cancer of the breast at sixty, leaving four daughters, A, B, C and D. Of these four two died of cancer of the breast and two of cancer of the liver.

A left three daughters, who at the ages of sixty-eight, seventy-two and seventy-eight, were alive and free from cancer.

B left two sons and four daughters. Of these the second son died of cancer of the stomach, three daughters died of ca of the breast, and one of cancer of liver.

C had two sons and five daughters. first daughter died of cancer of the b and left two sons and three daugh of whom the second daughter died of cer of the breast. C's second daug died of cancer of the breast, the thi cancer of the uterus, the fourth of ca of the breast, and the fifth of cance the liver.

D left one son who, at the age of sev was still free from cancer.

Of the larger series of cases repo Paget has published a series of t hundred and thirty-two cases, in sev eight of which a history of heredity obtained, while in Williams' series of hundred and thirty-six cases, thirty-t gave a similar history.

Hereditary cancer appears much frequently in the female than in the members of the affected families. Br case illustrates this peculiarity in a s ing manner. Mme. Z and fourteen o nineteen female descendants, who rea the age of thirty, died of cancer, w only one of the seven male descend died in this manner.

Clinical History.—Ordinarily, the symptom noticed by the patient is a h indurated, irregularly-flattened mas the breast, situated, as a rule, in the

FIG. 3. Mammary Cancer, Showing Retra and Elevation of Nipple.

per outer quadrant, although it may situated in other parts of the breast below the nipple. (Fig. 1.) The dis ery is usually made by accident, as, dinarily, there has been little or no vious pain or discomfort to attract at

tion. Occasionally, the development of the tumor is accompanied or preceded by a peculiar momentary stinging pain, which comes and goes, reappearing at in-

FIG. 4. Cancer of Breast, with Infiltration and Ulceration of the Skin, and Retraction and Slight Elevation of Nipple.

tervals ranging from a few hours to several days. This stinging may be limited to the affected breast or it may extend into the axillary space or along the arm. This pain is never severe, but when present it is very suggestive of cancer.

The idea that cancer of the breast is a growth which "eats into the tissues" and is, necessarily, accompanied by the most agonizing pain, is, unfortunately, deeply rooted in the minds of patients generally, and it is often difficult to convince them that a cancer can exist without causing appreciable suffering.

On examination, the cancerous nodule is found to be of a peculiar wooden hardness, absolutely devoid of elasticity. The hardness is most pronounced in the central portion of the mass. The borders are blunt, irregular, and, on account of the infiltration of surrounding tissues, vaguely defined. The tumor is not movable in the tissues, except in very fat women with loose, pendulous breasts, but is likely to be adherent both to the skin and the retro-mammary tissues.

In the majority of cases the nipple is retracted, that is, drawn inward toward the chest wall, as well as in the direction of the cancer. (Fig. 2.) For example, if the tumor is situated in the upper outer quadrant, the nipple is drawn upward toward the clavicle. (Fig. 3.) This point is of some interest from a diagnostic standpoint.

Dimpling of the skin over the tumor is almost pathognomonic of cancer, and the more deep seated the tumor the more certainly does the dimpling indicate carcinoma. In elderly women, even the slightest dimpling should arouse grave suspicion.

As the tumor increases in size the overlying skin becomes reddened and congested, and presents a characteristic "pig skin" appearance. The infiltrated skin soon breaks down, forming an irregularly rounded ulcer with a crater-like cavity, with thickened, indurated edges. (Fig. 4.) The floor of the ulcer is formed by the surface of the exposed cancer, and is covered with more or less necrotic shreds and with ill-formed granulations. There exudes from the ulcer a thin, acrid, often blood-stained ichorous discharge, with a peculiarly penetrating and offensive odor. The ulcer progressively increases in size and shows not the slightest tendency toward healing.

The cancer not only invades the skin, but it extends backward into the retro-mammary tissue, and the pectoral fascia, and may even penetrate the chest wall and involve the pleura. (Fig. 5.)

As the disease progresses, the axillary lymph nodes become enlarged and matted together, making a hard nodular mass, which fills more or less completely the axillary space. (Fig. 6.)

Often there is noted a fullness in the clavicular region of the diseased side

FIG. 5. Extensive Carcinoma of Breast.

which is not present on the other. This means that the infection has spread along these lymphatics and may extend along the chain accompanying the internal

mammary artery, or may involve the bronchial glands at the root of the lung. Occasionally, the axillary enlargement becomes so excessive as to seriously in-

FIG. 6. Cancer of Breast Showing Retraction of Nipple, Ulceration of Skin and Enlargement of Axillary Lymphatics.

terfere with the brachial circulation and edema and even gangrene may result. (Fig. 7.)

In advanced cancer of the breast cachexia is often marked. The patient loses her appetite and becomes weak, pale and emaciated, the skin showing a peculiar yellowish pallor.

The diagnosis is based on the age of the patient, the presence of a hard, immovable, inelastic, rapidly-growing tumor, with irregular, infiltrating margins, dimpling of the skin, the formation of adhesions between the tumor and the skin and retro-mammary structures, ulceration, the comparative absence of pain or tenderness in and around the tumor, the presence of an occasional momentary stinging sensation, and the presence of enlarged lymph nodes in the axilla, and sometimes the supraclavicular region on the affected side.

The prognosis is always grave, but there is considerable difference in the degree of malignancy in different ca Under ordinary circumstances a scirr cancer of the breast, if untreated, kill the patient in from two to t years, while a medullary cancer runs course in a year or less. There are, h ever, certain considerations which ar some assistance in estimating the pr ble duration of any given case. The is of the greatest importance. In br cancer the younger the patient the m rapid the course of the disease. In tients over seventy-five a cancer may almost indefinitely, the patient eventu dying of some intercurrent affection. cancer also runs a more chronic cou in a thin and scrawny patient than in of a more pleasing plumpness. Early volvement of the skin and lympha renders the prognosis very grave, w if the tumor is pigmented, or if gen dissemination has taken place, the p nosis is hopelessly bad.

With operation, as a general rule, earlier the operation the better the p nosis, but, of course, there are except to this rule. Taking the cases as t

FIG. 7. Showing Edema of Arm in Case Atrophic Scirrhous Cancer of Breast.

appear, the favorable, the indifferent, the hopeless, when operated on by modern radical methods (Halsted's Meyer's), approximately forty per

are cured, and to be considered cured a patient must be absolutely free from all signs of cancer for at least three years after the operation. With selected favorable cases this percentage could undoubtedly be materially increased.

The treatment of cancer of the breast is essentially surgical. There is no drug or remedy as yet known which will, with any degree of certainty, retard the progress of cancer. The X-ray may be used as a palliative measure in inoperative cases, in the hope of at least relieving some of the more distressing symptoms, but the results from this treatment are not sufficiently positive or certain to justify its employment in cases amenable to operative treatment. Caustics and so-called cancer pastes are employed in some cases with undoubted success, yet their disadvantages are so great and their advantages so small, as compared with operative treatment, that I can see very little to recommend in these relics of surgical barbarism.

Treatment of Typhoid Fever.

BY RALPH M. MORRILL, M. D.,
Lincoln, Neb.

In this age of therapeutic nihilism, a discourse on this subject from a medicinal standpoint is out of the ordinary and distinctly irregular; but I have found by comparison that the general run of cases get along best that are treated from an intelligent therapeutic standpoint. It is also essential that one have a thorough knowledge of the disease from a pathological standpoint, so as to be able to recognize all conditions rightly when they present themselves.

That which has done most to discredit medicinal treatment is the so-called antiseptic or germicidal idea as regards the intestinal tract. From Woodbridge down to the present time, the idea has been to sterilize the gastro-intestinal mucosa, so that no wonder, to our own discredit, we leave it to the nurse; internal secretions, and functional activity of all the emunctories are lost sight of. We do not get at the basic lesion; as it stands now tympanitis and borborygmi must be relieved by salol, hemorrhage by opium, delirium by whisky, cold bath for pyrexia, and so on until the patient gets well anyway or dies from toxemia and exhaustion.

Classical typhoid does not embrace those types which are questionable, such as the so-called abortive type, typho-malaria, or typho-pneumonia; not but that disease conditions may take on typhoid manifestations, but the usual bacilli are absent, so we will take the typhoid case that runs from three to six weeks.

The usual case when seen has been feeling badly for some time, has the general prodromal symptoms, tongue coated, bowels constipated, anorexia complete. Castor oil, a sufficient quantity to produce a thorough evacuation, is given at once, and is the only agent for this purpose worthy of consideration. Enemas are all right to clean out the lower bowel, but are not to be depended on exclusively. The tongue will be coated a dirty white, pasty, will be broad and thick—an evidence of a disordered condition of the body fluids that will be benefited by the hypophosphite or sulphite of soda. I frequently give it until the urine is alkaline, the hyposulphite of soda in capsules and the sulphite in solution; the addition of chionanthus is generally beneficial, and on account of its selective action is most always indicated. If the tongue is inclined to become dry or fissured, dilute hydrochloric acid will be of much benefit, in place of the sulphites; in fact, during the fastigium and deferverscence, it is frequently indicated, and the indication will have to be looked for. A casual observation may see the tongue coated for the sulphites, but if you will examine more carefully you will observe that at the edges there is a beef-red appearance which indicates the acid. By maintaining a normal balance of the intestinal secretion by the acids or alkalies, you will find that diarrhea, tympanitis, anorexia, delirium, etc., are of minor importance. I frequently find a combination of this character useful:

℞ Dil. Hydrochloric Acid.....3 drachms.
Sp. Chionanthus.....4 drachms.
Sp. Hyoscyamus.....2 drachms.
Elix. Lac. Pepsin.....q. s.....4 ounces.

M. Sig.: Drachm every three hours.

For the pyrexia I use a combination, giving the mixtures in five-grain doses every three hours. The cold bath is a travesty on good judgment; it stops radiation and produces visceral congestion, and I have never seen anything but bad results from its continued use. Cool or lukewarm sponging is indispensable, or a cool compress to the abdomen will not inhibit radiation; the addition of alcohol to the water is of value also. Hypostatic congestion of lungs is most always relieved by changing the patient's position; delirium is treated by the application of cold to head and a half grain of codein. Hemorrhage is treated not by ergot, opium, etc., but I make a tincture of oil of erigeron and oil of cinnamon, one drachm of each to two ounces of alcohol, the dose being from five to thirty minims, and add small doses of ipecac and belladonna to the mixture, with better results than anything else. Charcoal and milk have been helpful in some cases. Outside of normal salt and camphorated oil I know of no satisfactory stimulant.

From a dietary standpoint I consider fruit juices essential—orangeade, lemonade and grape juice are preferable; sweet milk, buttermilk, matzoon or koumiss, egg creams, vegetable soups, tomato in particular, and beef broth sparingly. This is variable enough and will not grow monotonous.

In hygienic considerations there is nothing new. I use a saturated solution of bichloride of mercury to disinfect all excreta.

To treat a subject of this kind exhaustively requires a volume. To sum up, we do not need too much antisepsis from a germicidal standpoint; we should strive to establish a normal condition of functional activity of all structures from the peptic glands to the crypts of Lieberkühn, and results will usually be found satisfactory.

Brownell Block.

The MEDICAL BRIEF has been called the Medical Bible by more than one of our friends, but has it ever occurred to you who have seen it that it is the cleanest of all medical journals in its expressions and illustrations? No language is used that is not expressed in a delicate way, and purely scientific in its thoughts and meaning.

[Written for the MEDICAL BRIEF.]

Hyper-Oxidized Hydro-Carbon Treatment in Tuberculosis — Oxygen Liberated in the Stomach from Oxides — Hemoglobin as Oxygen Accumulator.

BY PROF. E. C. GETSINGER,
Biologist, Washington, D. C.

What relationship oxygen inspired holds to life, and the processes by which it is capable of perpetuating life, is known only in a most limited way. That oxygen, once in the circulation, becomes subject to conversion into energy, motion or vitality when combined with the other processes akin to life, is but general knowledge. It can not be considered severally only in so far as it is the principal substance which aids in sustaining life. The lungs are considered to be the principal, in fact, the only solitary means of conveying oxygen to the blood.

So was the stomach formerly considered in its function until rectal feeding was discovered and found to be a successful recourse. Then why not liberate oxygen in the stomach, and there taken up by the circulation when the lungs are impaired by disease? Is not almost every form of food consumed some form of an oxide? and is the oxygen not liberated? Or does the system reject the same from that source because of the non-ethical manner in which that life-force dared enter into the chemical brotherhood. Would not such a form of liberated oxygen treatment in the stomach be the panaceal treatment for tubercular patients whose healthy lung areas are so decreased as to enervate them, and thus render them even more subject to the processes of dissolution.

In tuberculosis we enter a realm of mystery greater than anything in the index of diseases. I am not inclined to invite unnecessary prejudice of the profession by reciting the results of twenty years of research, thought, meditation and experience in this direction—at least not in America. I know them too well, as a class, for that. I will thus confine myself more to ancient facts and endeavor to throw a flicker of common sense on them, which may appear as a new light,

and in so doing it is my aim to exhibit more common sense than erudition.

The ancient facts record that hemoglobin constitutes ninety per cent of the blood composition. That the ratio of molecular composition is, carbon, six hundred; hydrogen, nine hundred and sixty; nitrogen, one hundred and fifty-four; sulph. iron, three; oxygen, one hundred and seventy-nine. That hemoglobin has a great affinity for oxygen; yet, while in solution a molecule of hemoglobin holds a ratio of only one hundred and eighty of oxygen to one thousand nine hundred of other constituents. That it readily liberates its burden of oxygen under certain circumstances, or in other words, hemoglobin has a function of holding quantities of oxygen as an accumulator rather than a solvent of oxygen. Only a small portion of oxygen inspired remains in the blood as a gas. Over ninety per cent is combined in the form of an oxide, and thus enters into the blood and tissues. In this oxidic form I believe it enters the circulation by way of the stomach. It is also true that the plasma likewise holds only a small portion of oxygen in simple solution. That the blood, as a whole, contains more carbonic acid than oxygen, in a ratio of twenty volumes of oxygen to thirty-nine and forty-six volumes of carbonic acid in one hundred parts. The chief part of oxygen is contained in the blood corpuscles, but not in a simple solution either, but in a form of an oxide, with the molecular arrangement so constituted that the oxygen is but loosely held together, and which is readily liberated when other functions require it.

To supply tubercular patients with sufficient oxygen is now the cry of the medical profession the world over, and in being at a loss as to how to proceed by medication, open air and altitudes are the only means at hand. When oxygen is taken into the lungs or stomach in quantities from a tank or other contrivance, it can only result in too rapid chemical action and tissue changes, and become an irritant, as is proven by dioxide upon lesions. But when administered in a compound, or in an oxidic form, where there must first a process play upon the compound before the oxygen is liberated, then such inflammatory dangers are avoided, by slow and gradual liberation, giving the hemoglobin time to prepare for its accumulation as rapidly as it is given up. I thus consider the oxygen tank a means of "rapid transit" in many cases. Furthermore, along this line we find that a molecule of hemoglobin contains six hundred atoms of carbon, an element which has the greatest affinity for oxygen, with a power of attracting at least ten to one, of oxygen. Then hydrogen, at nine hundred and sixty atoms, has the power to attract at least twice its bulk of oxygen. Thus, one molecule of hemoglobin, broadly considered, has the accumulative properties of holding in loose solution at least eight times its bulk of oxygen, without altering its own chemical composition one iota.

How does it do this? Apply the principles involved in storage batteries, and you have the answer.

When the assimilation of carbon is reduced or imperfect, the hemoglobin becomes carbohemic for want of the element which can possibly hold the oxygen after being inspired, because a single atom less of carbon means, perhaps, ten less of oxygen, and since the majority of tubercular patients suffer from some form of intestinal indigestion which affects the assimilation of carbon, we need not look far for the seat of the principal disturbance. The deficiency of oxygen in the blood, caused by the lack of carbon in quantity, renders the patient subject to the ravages of the tuberculous processes, the resistance being diminished, and with normal chemistry disturbed, only morbid processes are possible. The tubercular patient can be saturated with oxygen by any of the various methods, yet if the carbon is deficient, so that the accumulative power of hemoglobin is diminished, then the patient becomes enervated in spite of oxygen, because proper oxidation does not take place. The hemoglobin holds oxygen in reserve supply—ready to be converted into whatever form of energy the body might demand. It seems to act similarly in this respect as does a juggler of balls—holding five balls in one hand for disposition by the other, yet is receiving another ball in the place of each one as soon as disposed of. The ball

never is and never was a part of the hand, nor are the atoms of oxygen, above a certain number, a part of the hemoglobin. Where the supply of oxygen is not equal to the demand, and the hemoglobin is overdrawn on its reserve supply, it will naturally yield up its own oxygen, as far as possible, and thereby the normal quantity of hemoglobin be reduced. Where the healthy lung area is so diminished by disease as to render the supply of oxygen insufficient for normal oxidation of tissue, then morbid processes ensue, residual animal tissue accumulates, and, finally, various bacillus form—possibly of spontaneous origin—only to add their toxic influence to the whole condition.

Saturation with oxygen is not possible in cases where air cells are collapsed, paralysis of the lungs exists, hepatization and congestion interfere, unless oxygen can be liberated in the stomach, and thus thrown into the circulation. It is possible, and is a fact. It has been done for years with surprising results in tuberculosis of the lungs, successfully in even the thir stages, where cicatrization of cavities followed and became filled in with scar tissue, as will physicians associated with me in experimental work testify. Over eighty-six per cent of cures, without relapse after from one to five years, some cures made twelve years ago are perfectly well to-day.

Then, also, as soon as the supply of oxygen becomes low, and the hemoglobin has already parted with as many of its one hundred and seventy-nine atoms per molecule as it can possibly spare, then nature seems to arouse itself in an effort to consume the unoxidized matters in the blood, a wave of endeavor is manifest, only to fall back disheartened, because in the impoverished state of oxygen the effort could only result in water—night sweats, respiration being less at night time than in active moments, hence less oxygen, thus toxic matter accumulates, while the enervated state can not generate sufficient energy for combustion, but only enough to form H_2O.

As soon as such a patient is properly supplied with both oxygen and carbon, then the night sweats cease, simply because normal combustion is taking place, and toxic matters burdening the blood and tissues are being oxidized. This result has been attained in over two hundred cases which I have had the opportunity to observe, wherein patients were fed every thirty minutes with a form of hyperoxidized hydrocarbon, the carbon taken from any of the various balsam and essential oils, excessively oxidized, placed in a medium of fats derived from grape sugar. The oils being first treated so as to eliminate their toxic properties, or else patients would have to be under careful observation every moment of the day.

Almost daily I am disputed in the fact that oxygen can be liberated in the stomach, and then be taken up in the circulation, and this from men of reputed intelligence. Whether this is a more general belief among the medical brethren I do not know, but to settle the question once for all, I will quote from one who had sixteen years of intimate acquaintanceship with Justus Baron Von Liebig, of the University of Giessen. I refer to William Gregory, M. D., F. R. S. E., Professor of Chemistry, University of Edinburgh, who, as far back as 1850, wrote in his work on "Organic Chemistry," page 576: "This proves that the formation of fat from sugar in the animal body, which certainly takes place, is a source whence the blood may obtain oxygen when respiration is impeded."

It is still the practice, to a great extent, to treat patients who show anemic or tubercular tendencies, with iron in some form, in the expectation of rendering the blood normal. But when we consider that in one molecule of blood corpuscle we find, perhaps, only three atoms of iron against six hundred atoms of carbon, then this seems to indicate that but little meditation is given to this all-important subject of medicating according to the chemical requirements rather than the "fads." To treat such conditions with a digestible form of carbon, and when combined with oxygen, the value is greatly enhanced, would appear to be rational treatment, for such medication not only supplies a limited supply of oxygen, but induces the carbon as well, which will in time be taken up by the hemoglobin, and there hold, perhaps, eight times its bulk of oxygen besides. The carbon from vegetation is more readily converted into blood prop-

erties. If this were not true, then feeding on charcoal or coal dust would give the same results.

All treatments for tuberculosis brought to light during the past fifteen years, were successful only in so far as the remedy contained carbon and oxygen. The more of those elements the more successful the treatment, yet not one of the numerous treatments of that period made it possible to saturate the patient with oxygen. The old essential oil treatment has never been surpassed, as far as medication for tuberculosis is concerned. It was the toxic dangers which caused the medical profession to discard it, and not the failure to cure that disease. Instead of overcoming the difficulties, they sought other less dangerous methods and, finally, adopted creasote, which in the end only created irreparable stomachic disorders. And in this form of medication it only succeeded in overcoming tuberculous conditions in ratio to the oxygen and the very small volume of digestible carbon it contains.

Nearly all tuberculous patients suffer from some form of intestinal dyspepsia—malassimilation of carbons, and thus nitrogen or carbonic acid are absorbed to excess. Then why feed such patients on nitrogenous fats?

Practitioners have spent years in an endeavor to treat tuberculosis with a germicide, after Koch discovered the bacillus, only to finally—and without much noise—find that the bacillus is the effect, not the cause *per se*, of the disease. Then followed the essential oil treatment, then codliver oil, then creasote, then various serum treatments from the French school, and, finally, open air, milk and egg diet—albumen for the hemoglobin, instead of carbon. Yet with all of these methods of treatment, tubercular patients are now a thousand to where there was one when I began my experiments. In those days there was no alarm. I simply took it up as one of the problems of that day, never dreaming that before my work was completed that the disease would assume the proportions of a plague, nor did I ever anticipate that the medical profession would ever say "that no cure would ever be found," and with such pessimism openly teach a suffering public that no hope is held out, even to their generations.

I understand that the MEDICAL BRIEF has a large European circulation, and since I desire very much to bring this treatment into the hands of various foreign governments for the benefit of humanity, I take this means of bringing my proposition to the possible notice of the profession in those countries.

I have vainly tried to give my discovery to the United States Government, but it is only in a position to take notice of discoveries in processes of new gun metal and kindred merciful (?) ideas.

I propose to place the discovery into the hands of any government for the purpose of manufacture and distribution to the physicians. There are no patents connected with the processes, but the raw materials are exceedingly dangerous, and to place the process into the hands of careless operators is out of the question.

I have unlimited confidence in the treatment, and back up my sincerity with a proposition that I will furnish free of cost sufficient hyper-oxidized hydro-carbon tablets for a complete course of treatment of one hundred patients, and this with each country.

The test to be made by physicians as a body authorized to deal with the matter by their respective governments, and if satisfactory results are attained, the entire matter will be turned over to a commissioner and the knowledge connected with the manufacture, the governments to only pay the necessary expenses connected with the transaction.

I can not treat with physicians individually, nor those desiring to enter into a business arrangement. The treatment ought to be kept out of mere profit-sharing endeavors.

The distribution to physicians in the United States has been turned over to a physician of repute in New York City, a member of the A. M. A.

150 East Capitol Street.

[Written for the MEDICAL BRIEF.]

General Remarks of the Pelvic Floor.

BY BYRON ROBINSON, B. S., M. D.,
Chicago, Ill.

(Continued from page 555.)

The levator ani fascia proximal and distal is the real visceral support. I think it was Dr. Meyers, a German physician, who first happily named it the pelvic diaphragm. In many subjects it is membranous. The normal muscle has the shape of a boat, and when this boat-shape becomes cone-shaped, the pelvic floor is impaired. The levator ani is composed of many muscular bundles coursing chiefly parallel to each other, but also at varying distances. The bundles are flat, ribbon-like, and of a bright red color. The bundles of muscular fibers are maintained at greater or less distance from one another by collections of fat or connective tissue in varying degrees. Fenestra, or apertures, are commonly observed between the muscular loops. The capacity of the bundles of the levator ani muscle to separate and reunite without injury, serves a useful purpose in labor, when rapid and wide distention of the pelvic floor may occur. Too many figures illustrates the muscle as a distinct plane with no parallel gaps between the bundles.

The levator ani (the deep, muscular layer of the pelvic floor, is connected to the external sphincter ani of the rectum and vagina), the superficial muscular layer of the pelvic floor, and by this muscular connection to the perineal body (the punctum fixum), the deep and superficial muscular layers of the pelvic floor are maintained in intimate relations of much utility. A few fibers are lost in the perineal body. The levator ani is in closer organic relation with the rectum than the vagina, because the rectum requires more frequent and perfect evacuations than the vagina. It is chiefly a sphincter muscle. The weakness or limited degree of its origin and insertion, and the direction of its fibers, are in accordance with its fading existence.

The proximal curve of the rectum is due to the horseshoe-shaped loop of the levator ani, which originates chiefly from the dorsal surface of the pubis. By the contraction of the distal stronger fibers of the levator, the distal portion of the rectum is forced against the perineal body, which compels the anus to turn dorsalward and to evacuate its contents. The levator ani, on account of its form and dimension, allows deficiencies in the pelvic floor, which are occupied, ventrally, by the bulbo-cavernosus and dorsally by the coccygeus muscle, its continuation backward.

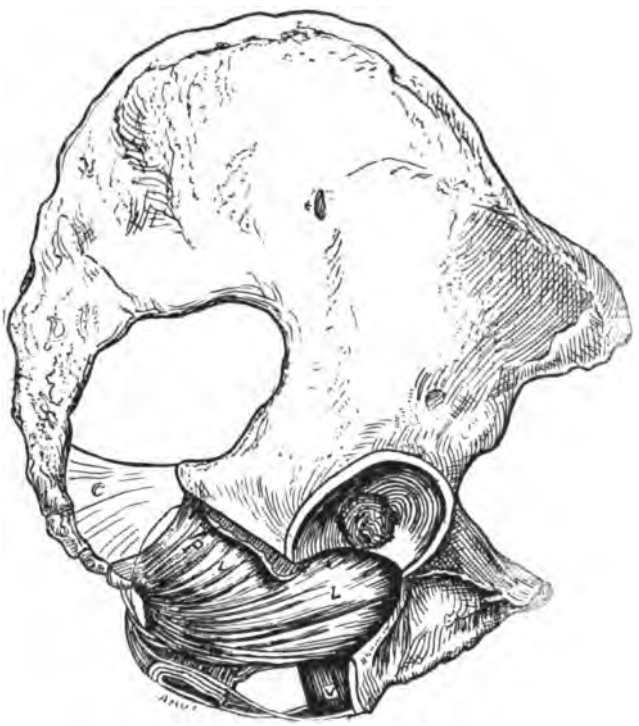
The palpable rounded border of the levator ani lies three-quarters of an inch proximal to the anus and three-quarters of an inch proximal to the vaginal aperture, making the muscle, in fact, a regulator of the external apertures of these two canals. Normally, the orifices of the canals are maintained closed by sphincters. They remain patent only by internal or external force, or from trauma. The levator ani will elevate from five to twenty pounds, averaging about ten, as noted by Dickinson. As every gynecologist knows, its strength soon tires assistants in vaginal hysterectomy. From its insertion into the perineal body the external sphincter, post-rectal raphe and coccyx, it draws ventralward the post-vaginal structures of the pelvic floor. In the excellent work of Savage, he names the portion from the principal bony origin, pubo-coccygeus. This is erroneous, as these loops do not pass as far dorsal as the coccyx—do not even come in contact with it. The levator elevates the rectum and vagina ventralward and proximalward to the pubic arch. The muscle has but limited influence on the lateral wall or borders of the rectum. The muscular fibers composing the horseshoe loop exercise the chief influence over the dorsal rectal wall, while the portion of the muscle arising from the white line (fascia) serves its purpose by maintaining the pelvic diaphragm in relation prepared for any immediate action; with its proximal and distal fascia it makes a tense floor for the superimposed viscera.

The levator ani fascia proximal and distal lends the muscle its greatest utility by increasing its strength, and also producing harmonious action in its function. The horseshoe sling is inseparably blended with the sphincter ani externus. The levator ani produces the H-shaped condition of the vagina by lateral pressure,

and its puckered or constricted appearance at the orifice. The muscle becomes hypertrophied during pregnancy and vaginismus. It resists the head in labor to a surprising degree. It may be easily observed in slow labor, when, if small forceps sufficient to overcome the tension of the muscle be applied, labor proceeds rapidly.

The comparison of the diaphragm (diaphragma thoracis) and levator ani (diaphragm pelvis), as to the capacity for strength is in favor of the levator ani. Its strength varies much in different subjects. The best descriptions of the levator ani muscle are given by Henle, Luschka, Testut and Lesshaft. Hart and Dickinson, Studdiford, have made excellent studies on this muscle. Browning and Peter Thompson wrote interesting articles on the subject. The levator ani may be a rudimentary muscle, disappearing with the tail and in the evolutionary process of an erect attitude. This view may arise from the weakness of its origin, the direction of its fibers and insertion, as well as the requirement of the double fasciæ. It is unphysiologic for a muscle to produce constant support, hence the levator ani can not be considered a continuous support for the viscera; it is rather a sphincter muscle.

The levator ani muscle is analogous to the buccinator muscle, or the ocupitofrontalis. Perhaps from an evolutionary standpoint we may look on the levator ani as having three functions, viz.: (a) of a sphincter; (b) of an elevator; and (c) of a tensor of the levator ani fascia proximal and distal. As proof that the levator ani is a sphincter one need only introduce the finger into the vagina and request the subject to contract the muscle. Cruveilhier, Henle, Lesshaft and Budge insist that the levator ani is a sphincter of the anus and distal rectum chiefly, and not an elevator. That this muscle is an elevator, one need only dissect it to find the muscle ending definitely in the walls of the rectum, and such ter-



LATERAL VIEW OF THE LEVATOR ANI MUSCLE.

FIG. 9. L, L, the curved levator ani muscle surrounding the rectum; V, vagina. The grasp of the levator ani muscle on the rectum is here evident. P, the levator ani fascia distal represented in a roll. (Luschka)

minating fibers, when in action, could only elevate the rectum. The horse during defecation illustrates that the levator ani is an elevator, as the rectal wall is elevated, the rectal mucosa everted and completely evacuated. As an elevator, it resists intra-abdominal pressure.

The levator ani appears as well developed in the male as the female, and hence labor does not appear to develop it. The levator ani muscle is greater in those animals with a tail, and originally its chief function was to aid in managing the tail, from which it would appear that as a tensor of the levator ani fascia proximal and distal these fibers take an active part. They originate at a definite fixed point, lose themselves between the fascial blades and do not extend to rectal or vaginal walls. When a muscular fiber neither goes to the rectum nor ends in its wall, it will not act as a sphincter, nor as an elevator, except in mass or adjacent connection.

Lesshaft and Roux divide the levator ani into two layers, viz., (a) the internal proximal layer, which is an elevator, and (b) the external distal layer, which is a sphincter.

The trigonum urogenitale forms a muscular tendineous plate, possessing the form of a triangle, located in the subpubic angle, and is pierced by the urethral and vaginal tubes. The essential constituents of the trigonum urogenitale forms the muscular trigoni urigenitalis, which is related to the vagina as the levator ani and coccygeus is related to the anus.

In short, one might state that the pelvic floor consists of two anatomic segments, viz.: (a) the levator ani (plus the coccygeus) with their proximal and distal fascia and related distinctly with the rectum; (b) the musculus trigoni urogenitalis plus the ligamentum trigonum which is distinctly related to the vagina (and urethra).

The fascio-muscular apparatus of the pelvic floor spans the osseous-ligamentous space in the pelvic exit, and practically consists of two different segments, viz.: (a) the diaphragma pelvis; (b) trigonum urogenitale. The diaphragma pelvis practically extends over the general pelvic floor, forming a funnel, the outlet of which is represented by the anus. The foundation of this funnel is the levator ani muscle (together with the coccygeus muscle). The levator ani is practically connected and related to the anus.

The levator ani plus the coccygeus muscle forms the muscular pelvic floor, on which rests the pelvic viscera and for which it possesses exit apertures. Dr. Howard A. Kelly, in my opinion, attributes excessive powers of support to the muscularis of the pelvic floor while deficient power is attributed to the pelvic floor fascia. To illustrate that the pelvic musculature is not the main support, we may suggest that the muscles of the pelvic floor characteristically originate and terminate in fascia, tendons.

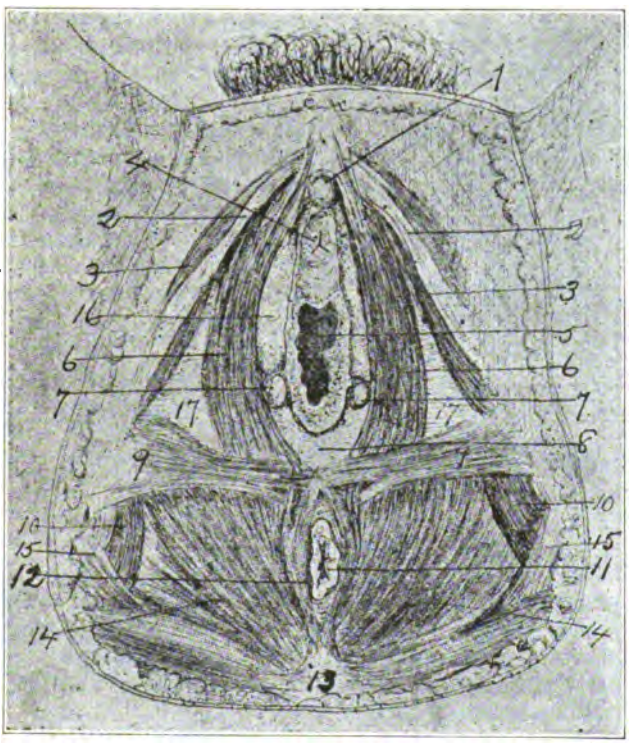
The dorsal portion of the levator ani muscles presents a funnel form between the ischial spine and coccyx.

As regards the minute division of the levator ani into separate independent bundles or muscles, much depends on personal taste. For example, W. A. Newman Dorland remarks that the levator ani is really composed of four paired muscles, designated as ischio coccygeus, ileo-coccygeus, pubo-coccygeus and pubo-rectalis, or Holl's sphincter recti. These simply indicate points of origin. Most anatomists divide the levator ani into two muscles, viz.: (a) muscularis-pubo-coccygeus and (b) musculus ilio-coccygeus. In general the levator ani originates from the lateral parietes of the lesser pelvis, passes distalward and medianward, uniting with its apposite fellow to form the muscular pelvic floor. It aids to support the pelvic viscera and surrounds the structures which penetrate it. The levator ani restores the pelvic floor to its normal position subsequent to the efforts of parturition, defecation or urination. It is a muscle of forced expiration. If the dissector divides the levator ani into two muscles—pubo-coccygeus and ilio-coccygeus—the pubi-coccygeus will concern itself with the rectum, one part of its fibers acting as a sphincter recti, the other part as a compressor recti (Holl's muscles), while the ilio-coccygeus is chiefly a supporter in the pelvic floor. The levator ani is supplied by a branch from the ventral division of the IV sacral and a

branch from the pudic nerve which relates intimately with the genitals.

Space forbids descriptions from comparative anatomy. However, the main change in man's pelvic muscles and fascia from that of lower animals is due to absence of tail and erect attitude.

2. *Coccygeus Muscle* (*musculus coccygeus*).—The musculus coccygeus is a flat triangular muscle arising by its apex chiefly from the ischial spine and lesser sacrosciatic ligament. It extends medianward, fan-shaped and becomes inserted by its base in the lateral border of the two distal sacral vertebræ and two proximal coccygeal vertebræ. The coccygeal muscles assist the levator ani and pyriformis in closing the dorsal portion of the pelvic floor or apertura pelvis distal. The relations of the coccygeus are: its ventral border is in contact with the dorsal border of the levator ani, however, separated from it by a connective tissue tract. Its dorsal border is in relation with the distal border of the pyriformis. Its proximal surface relates itself with the rectum. Its distal surface is in relation with the lesser sacro-sciatic ligament. It is supplied by a nerve branch from the IV and V sacral. The coccygeus muscles (bilateral) elevate and support the coccyx subsequent to its pressure dorsalward from defecation or parturition. The coccygeus muscle is one of the typical examples of a muscle becoming transformed into a fibrous tendinous band, fascia, from recession or deficient use (as the coccygeus was originally a powerful lateral caudal motor in primitive mammals).

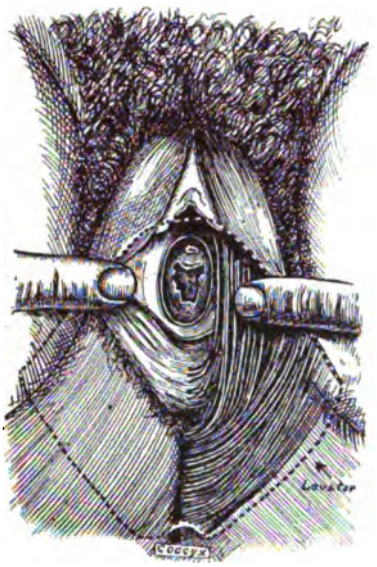


SUPERFICIAL MUSCLES OF PELVIC EXIT.

FIG. 10. I drew this illustration semidiagramatic to illustrate the general view of the muscular pelvic exit and its relations. 1, clitoris; 2, crura clitoridis; 3, erector clitoridis musculus; 4, urethra; 5, orificium vaginam; 6, musculus bulbus cavernosus; 7, pudendo-vaginal glands (of Duverney, Bartholin, Tiedeman); 8, dorsal vaginal commissure; 9, musculus transversus perinei; 10, musculus obturator internus; 11, anus; 12, sphincter ani externus; 13, coccyx; 14, musculus levator ani; 15, ligamentum sacrum, scraticum major; 16, bulbus vaginæ; 17, deep layer of superficial perineal fascia.

3. *Pyriformis* (*Musculus Pyriformis*).—The pyriformis is a flat, pyramidal muscle. Its origin is on the lateral borders of the II, III, IV sacral vertebra

from the distal border of the major sacro-sciatic notch and from the major sacro-sciatic ligament. Its course (partly internal and partly external to the pelvis)



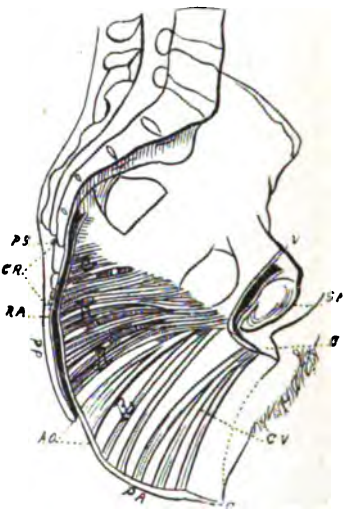
LEVATOR ANI MUSCLE AS VIEWED THROUGH THE SKIN.

FIG. 11. The pelvic exit is dotted. The directions of the levator muscle is evident (illustration from Dickinson, 1889).

is through the major sacro-sciatic foramen. It is inserted by a rounded tendon in the proximal border of the trochanter major. It affords a bed on which the sacral nerves can rest and be protected. The pyriformis and coccygeus muscles appear as a continuation of the levator ani and to line the distal as well as the dorsal pelvic wall.

4. *Sphincter Ani Muscle Externus.*—The sphincter ani externus is a thin, flat plane of an elliptical form. It arises from the coccyx, adjacent skin and superficial fascia. In its course it encircles the rectum and becomes inserted into the central tendon of the perineum, the skin ventral to the anus and other muscles. It is supplied by branches from the nervus penendus. The sphincter ani is intimately adherent to the integument surrounding the margin of the anus. The length of the sphincter ani is about four inches and its breadth on the lateral border of the anus is an inch. The sphincter ani maintains the anus continually closed. It can be firmly contracted by will, as in forced expiratory action (controlling contents). It being inserted in the coccyx, it aids to fix the central point of the perineum so that the accelerator urinæ may act. The sphincter ani aids to strengthen the pelvic floor by its action on the anus, as also by its attachment to the centrum perineal on tip of the coccyx. The anal group of muscles—levator ani, coccygeus, pyriformis and sphincter ani—so far as muscular support is concerned, play a major role in the perineum. They do not lend the perineum of pelvic floor its main support nor strength that is performed by fascia. Muscle functionates, fascia supports. Fascia is the corner stone to bear burdens forced on it by muscles.

Insertion.—From this description of the levator ani from actual dissection it will be observed that the insertion of the levator ani is: (a) on the opposite side of the pelvis from the identical location of its fellow origin; (b) to a limited degree



DISTENDED LEVATOR ANI.

FIG. 12. The elongated and separated bundles of the levator ani are here presented. V, bladder; SP, symphysis; C, clitoris; CV, constrictor of the pudendum; F, fourchette; PA, ventral perineum; AO, anus; PP, dorsal perineum; CR, coccyx; PS, distal point of sacrum; RRR, marks the distended levator ani in separated bundles. The middle R is on the most powerful bundle. The capacity of the levator ani muscle to separate into bundles, fasciculi aids to prevent rupture. Multiple muscular fasciculi separated yield more extensively than if in one solid bundle (Varnier after Dickinson).

in the median tendineous raphe; (c) some fibers may be inserted in the coccyx, rectum, vagina, perineal body, external rectal sphincter.

The white line, arcus tendineus. The crescentric, curved line, of ligamentous origin of the levator ani is profoundly connected with the pelvic fascia and the muscular fibers of the levator ani begin as tendineous fibers which form the white line. The ligamentous origin of the levator ani muscles is the blended, coalesced, powerful, fibrous fascial planes of the levator ani proximal and distal.

II. PUDENDAL GROUP OF MUSCLES.

In the pudendal group of muscles of the pelvic floor or perineum, I shall include, 5, Sphincter vaginæ (or Bulbo covenosus); 6, erector clitoridis; 7, transversus perinei superficial; 8, transversus perinei profundus. This group of muscles is intimately related to the pudendum in controlling the vaginal caliber, sexual relations and in maintaining the position of the pudendal orifice.

5. *Sphincter Vaginæ.*—Constrictor vaginæ, constrictor cunni, bulbo cavernosus. The sphincter vaginæ surrounds the distal end of the vaginæ. It is a double muscle. It *arises* from the distal border of the ligamentum triangulare or lamina aponeuratica and centrum perineale. In other words, it arises dorsally from the transverse perineal fascia midway between the sphincter ani and ischial tuberosity. A limited number of fibers is connected with the sphincter ani externus. The sphincter vaginæ becomes inserted by two bundles, the lateral of which attaches itself to the curve of the cruva clitoridis, and the medial bundle of which unites itself with that of its fellow distal to the clitoris into a single tendineous plate.

The sphincter vaginæ is a thin, broad, pale, red muscular layer. Through its sheet-like layer the blue bulb of the vagina shimmers. It surrounds the lateral vaginal walls. Its insertion into the bulb of the vagina, on the surface of the corpus cavernosum of the clitoris and in the mucosa between the clitoris and urethra suggests its sexual signification. Its contraction increases the turgidity of the bulb and hence limits the vaginal orifice —it is a sexual muscle, compressing veins and inducing erection of tissue. The sphincter vaginæ—bulbo cavernosum—partially occupies the space between the bilateral origins of the levator ani from the symphysis pubis. It not only surrounds the vagina but also the vestibule. It aids to strengthen the pelvic floor by means of its sphincter action on the vagina.

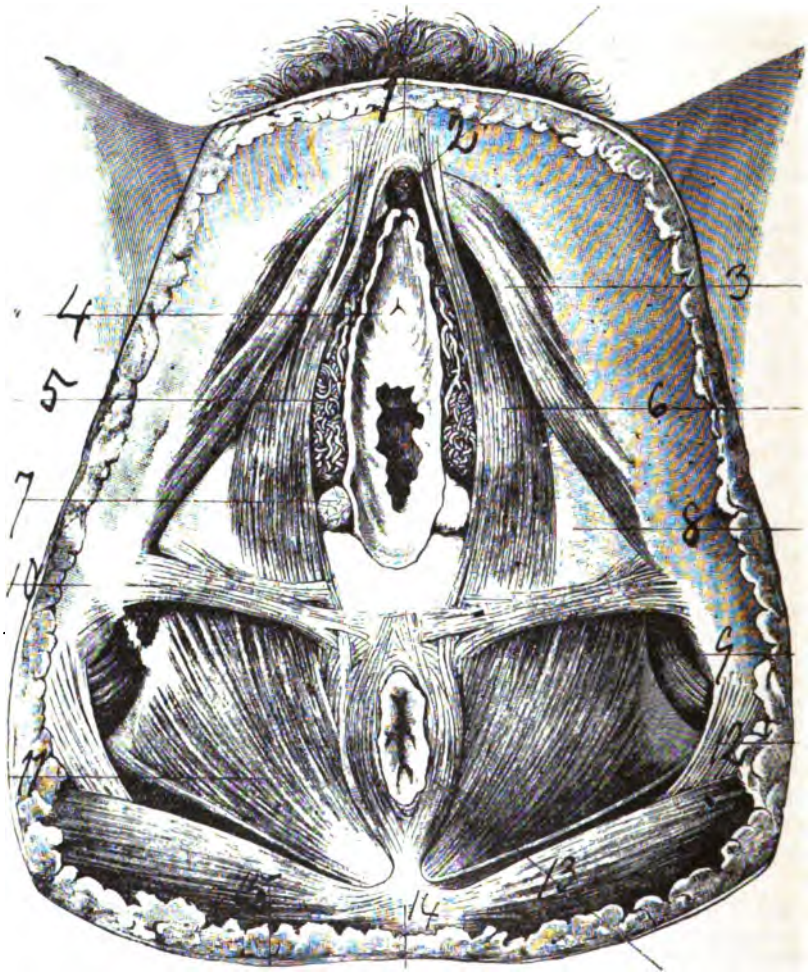
6. *Erector Clitoridis* (ischio-cavernosus. The erector clitoridis or ischiocavernosus muscle is located along the lateral wall of the vagina. It *arises* from the internal surface of the tuberosity and ramus of the ischium. In its *course* it embraces each crus clitoridis and becomes *inserted* in the fascia which envelopes the dorsal portion of the corpus clitoridis adjacent to the point of attachment of the ligamentum suspensorium. The erector clitoridis during contraction obstructs the return flow of venous blood inducing erection of tissue—it is a sexual muscle.

7. *Transversus Perinei Superficialis.*—The superficial transverse perineal muscles is practically a subcutaneous muscle or a subfacial muscle. It may originate from bone or fascia. In general it arises from the internal surface of the ischial tuberosity and varies in conjunction with the erector clitoridis and coursing medianward and proximalward becomes inserted in the centrum perineale. Some fibers may join the sphincter ani externus. Some of the fibers of the transversus perinei superficialis may be branched bundles from the levator ani. This muscle is intimately connected with the distal border of the trigonum urogenitale or triangular ligament.

8. *Transversus Perinei Profundus Compressor* (constrictor urethra).—Transversus perinei profundus (Hanle) *arises* from the internal surface of the junction of the rami of the ischium and pubes. It *courses* ventral to the urethræ and dorsal to the vagina. It is attached to the urethral and vaginal walls, blending with the opposite fellow. Unlike the male, the vagina divides the transverse perinei profunda. This muscle is intimately connected with the triangular ligament or trigonum urogenitale. On account of distribution adjacent to the membraneous urethra, this segment of the muscle is termed the compresor urethræ. Dr. H. O. Marcy states that at the central point of union the muscular fibres interdigitate or blend with the fiber of the levator ani.

The transversus perinei muscles are generally of less dimensions in woman than in man. They should be described practically as a muscular unit. They are variable in origin and dimension. Holl indicates that some of the muscles termed transverse perinei are branched bundles

jacent to that of the erector clitoridis, courses obliquely medianward and becomes inverted in the centrum, perineale intimately connected with the sphincter vaginæ, sphincter ani externus and trigonum urogenitale. The nerve supply of the sphincter vaginæ, erector clitoridis



MUSCLES OF PELVIC EXIT.

FIG. 13. Genitals subsequent to the removal of skin and superficial fascia. 1, ligamentum suspensorium clitoridis; 2, glans clitoridis; 3, musculus ischio-cavernosus; 4, orificium urethræ; 5, bulbus vestibuli; 6, sphincter vaginæ; 7, pudendo-vaginal gland; 8, musculus perinei profundus; 9, musculus obturator externus; 10, musculus transversus perinei; 11, musculus levator ani; 13, sphincter ani externus; 14, os coccyx; 15, gluteus maximus (Nagel after Savage).

of the levator ani, *i. e.*, parts of Holl's pubo-rectalis. When the transversus perinei muscles are distinctly developed, it may present a quill or little finger dimension, spheroid or flat band, intimately associated with the dorsal border of the trigonum urogenitale. It originates ad-

and transversus perinei arises from rami perinei of the nervus pudendus, and the vascular supply arises from the rami perenei of the arteria pudenda interna.

The topography of the transversus perinei presents points of interest in perineorrhaphy. The transversus perinei is a

landmark between trigonum urogenitale and anal region. The distal surface of the muscle is covered by fascia perinei, the dorsal free border of which surrounds the anal region. The proximal surface of the muscle rests on the aponeurosis of the trigonum urogenitale. It is intimately related with numerous perineal nerves, arteries and veins.

The pudendal group of muscles—sphincter vaginæ, erector clitoridis and transversus perinei—are of limited dimensions, and hence in contractile power. The erector clitoridis is a sexual muscle—aiding by its contraction to obstruct venous blood, and consequently inducing swelling, turgidity and erection of cavernous or erectile tissue. The sphincter vaginæ, though it constricts the distal vaginal orifice, is practically a sexual muscle, aiding by its constriction to obstruct the venous flow from the bulbus vaginæ, inducing swelling, turgidity and erection of this giant spheroid of collected veins. The transverse perinei maintain the tension of perineal fascia and the peritoneal relations of vaginal and anal orifices. It may be stated that the pudendal group of muscles become limited in dimensions, are also limited in their power to strengthen the pelvic floor or perineum; however, being intimately associated and interwoven with perineal fascia, they aid to consolidate and strengthen the pelvic floor in a minor degree. The anal group play the major role as muscular support of the pelvic floor.

[Written for the MEDICAL BRIEF.]

The Value of Faith.

BY R. C. CAVE,
St. Louis, Mo.

He who said, "We walk by faith and not by sight," stated a law of life which is true of all men, from the most ignorant peasant to the most learned philosopher. Faith is simply the conviction of the truth of something we do not know to be true—the assurance of the reality of something which lies outside the range of our knowledge. But the range of our knowledge is so limited that, if we did not base our action on the truth of something that lies beyond it, we would not act at all.

We can not know what a day or an hour may bring forth. Hence, every step we take out of the present into the future is taken by faith; every move we make toward the attainment of any end is made by faith. We do not know that we can attain the desired end; we only believe that we can, and are influenced by that faith to move toward it. The farmer sows his seed, believing that it will yield a desirable harvest. The merchant buys his goods, believing that he can sell them at a profit. The physician gives medicine to his patient, believing that it will prove beneficial. So, in all the affairs of everyday life, we walk by faith.

The same law holds in the realm of scientific research and discovery. The scientist observes, classifies, and compares facts, theorizes and experiments, reasons and deduces conclusions, but, his faculties being limited, he can not know that his information is complete or his reasoning free from fallacy, and, hence can not know that his conclusions are true. And when he has ascertained the order of nature with seeming certainty he can not know that this order will remain constant. "Obviously," says Mr. Huxley, "no amount of past experience can warrant us in anything more than a correspondingly strong expectation for the present and future. We find, practically, that expectations, based upon careful observations of past events, are, as a rule, trustworthy. * * * But, for all that, our highest and surest generalizations remain on the level of justifiable expectations; that is, very high probabilities." Hence, he who follows the light that science gives, walks by faith.

And it is even more manifest that we must walk by faith in our spiritual life. Our religion—whether it be blind obedience to an authority outside of ourselves or fidelity to the divine spirit within us; whether it be abject slavery to the doctrines and forms of the past, or an eager search for and progress toward better things—is but a reaching out after the unknown, prompted and directed by faith.

And faith not only prompts and directs the conduct, but it also moulds character. The civilization of an age or country is determined by its prevailing belief. When

belief in war is dominant, civilization is martial; when belief in commerce prevails, civilization is industrial. A prevailing belief in materialism produces an irreligious civilization, and a prevailing belief in the spiritual produces a religious civilization. Everywhere as the faith of men has been, so have been the men themselves. He who believes in money as the highest good becomes avaricious; he who believes in pleasure as the highest good becomes voluptuous. "As man thinketh in his heart, so is he."

It is only because faith thus influences life and moulds character that it has value. Considered in itself, it has neither merit nor demerit, and deserves neither approval nor disapproval. Apart from its influence on life and character, one faith is every whit as good as another. It is not faith, but manhood, that counts. We approve the good man and condemn the bad man, without waiting to find out what the one or the other believes. Thus, the intuitive moral judgment of mankind, giving expression to the sense of justice divinely implanted in the soul, declares that man ought to be approved or condemned, not according to what he believes, but according to what he is; and, hence, that faith is worthless, save in so far as it serves to lift the believer to a higher plane of manhood. The supreme question is not whether we believe in Moses or in Buddha, in Mohammed or in Jesus, in a personal God or in a divine principle, but whether our faith, whatever it may be, has so wrought in us as to incite us to just, generous, and noble lives, and make us pure and godlike in thought, desire, purpose and endeavor.

An Innovation.

A feature of the Ohio Valley Medical Association, to be held at Evansville, Ind., November 13 and 14, 1907, will be an evening session to which the laity are invited. Dr. Curran Pope, of Louisville, Ky., a notable orator, will deliver an address entitled, 'The Age in Which We Live." Dr. Brooks F. Beebe, of Cincinnati, Ohio, will deliver his address as retiring president of the association. We hope they will have a successful meeting and that much good will be accomplished.

[Written for the MEDICAL BRIEF.]

Recent Medical Progress in New York State.

BY SAMUEL S. WALLIAN, A. M., M. D.,
New York.

This State has, after long effort, much maneuvering, and much more or less bitter contention, set the pace, in the line of medical legislation, for the rest of the country, and, for that matter, for the rest of the unregenerate world.*

In effect it has permanently eliminated the question of sectarianism as regards the licensure of practitioners. As soon as the act just passed by the legislature has been officially put in operation, all medical coons will look alike to the non-partisan single Examining Board. No doubt the statute, as finally amended and passed, has faults; but the principle behind it is certainly based on reason and common sense. As experience demonstrates them lacking provisions can be added and unjust ones, if any there be, eliminated. This principle ought to have been enacted into law as soon as the Mayflower had landed her cargo and taken account of stock. There never should have been but one examining board, and but one standard of qualifications. Any other plan smacks of class legislation.

If a disagreement as to therapeutic means, methods and materials constitutes a school of medicine, then there are nearly as many schools as there are individual practitioners, since no two agree in their practice.

Sectarianism in medicine indicates superficiality of reason and narrowness of spirit. No man or set of men has the right to dictate what any physician shall use, or what he shall reject, in treating his patients.

The advocate of this or that exclusive theory or dogma to the exclusion and condemnation of all other rules, systems and theories is always a prejudiced bigot whose opinion on medical subjects is not worth the drop of ink expended in writing it out. He neither reasons himself nor comprehends the reasoning of others.

* Germany, France and Switzerland have always regulated their medical practice through single examining boards.

Every so-called "school" of medicine has had its mission, and added some valuable facts, to have their bearing on other facts applied to the art of healing the sick. This is true, even when applied to mystics, mental healers and Christian scientists, who are neither Christ-like nor scientific.

Medical colleges should be known simply as medical schools, without being tagged as the exponents of this or that "pathy."

Nature knows no "law of cure" save that of ceasing to transgress. She provides not in any case panaceas, but always inexorable penalties.

To cite a few of the nicknames and pseudo "systems," as they are bandied about by laymen and some doctors, "allopathy" never had other than an imaginary existence. It was a trumped-up nickname, fathered by Hahnemann. Homeopathy, eclecticism, hydrotherapy, physiotherapy, radiotherapy, serotherapy, mechanotherapy, osteopathy, and all the rest of the numerous tags are linguistic excrescences on the body of real medical science, ranging all the way from soft corns to sarcoma and chalky deposits in its joints.

If you or I know anything about the human organism, the nature of disease and the laws of living; if we have learned something of value in connection with the eradication of diseased conditions, it is our moral duty, as well as our professional business, to communicate our knowledge to the world, and to make our acquired skill available in alleviating human suffering and saving threatened lives. There is no earthly need of organizing our observations and deductions into a one-sided "system," and unstintedly denouncing those who do not see as we see and practise as we practise. Let us modestly advance what we have learned as fragments of the great whole of medical science.

It is high time that the medical world had outgrown and outlived every form of "pathy;" time that every student of the art of healing, which Byron styled the "Art of Killing Pain and Patients," should indulge no aspirations beyond that of becoming a true physician, broad enough to see all sides of a medical proposition, and intelligent enough to discern and adopt what is sensible, and avoid what is silly. When all medical men shall have fairly learned this rational lesson they will have earned the right to be called rational students of rational medicine, instead of petty partisans of some more or less inconsistent and incomplete schism. They will also earn the honor of being esteemed by their colleagues and co-workers in other professions as honest searchers after physiological, pathological and therapeutic truth, regardless of its source, or of its popular label.

The State of New York is to be congratulated on the stand she has at last taken. It is a step in the right direction, and if, as charged in some circles, surreptitious provisions were foisted upon the framers and sponsors of the medical act, just passed and signed by the governor, their injustice will appear, and future legislatures will unquestionably cull them out. Certainly all progressive medical men have cause to rejoice, while they recall Tennyson's "One law, one element, and one far-off divine event toward which the whole creation moves."

Another Treatment for Cancer of the Stomach.

BY DR. A. ROSE,
New York City.

While we are awaiting reports of the results with Jacobi's methylen-blue method to treat cancer of the stomach, we learn of a new remedy recommended with the same praise as Jacobi's. Dr. E. Funke (*Medicin. Blätter*, 1906, No. 44) speaks of remarkable results in several cases of cancer of the stomach, by means of brewers' yeast, taken fresh from the brewery (perhaps our Fleischmann's yeast cakes might answer as well). He writes the appetite, the digestion and the general condition improve very soon and tumors disappear. The treatment, a tablespoonful of brewers' yeast three times a day, before meals, has to be continued for, at least, a month.

Begging the Question.

BY T. A. SMURR, M. D.,
Ottawa, Ill.

For genuine unselfishness and personal self-abnegation for the good of their fellowmen has ever been the proud boast of our profession, and the midnight oil has been burned for ages that we might bring to the suffering world, not alone a panacea for their sufferings, but a prophylaxis for their every fil, so that life, health and happiness should be theirs galore, and we, relieved from their tales of woe, might make an equally precarious living in some congenial spot-cash pursuit. But the world persists in being sick, miserable, and dying, despite our most diligent, persistent and unselfish efforts.

Anent all this, a Scottish chiel sometime said of the profession:

> "Oh that some power the gift wold gie thee
> To see yesels as ithers see ye."

Then I'd been spared from giving you this unfriendly whack.

One of these big-gun professional philanthropists (in the memory of men still living) announced through the public print (so all might know and profit thereby) that he had discovered and identified the bacillus of tuberculosis, and, further, that he had a perfect cinch on him, and that by the use of his wonderful legacy to the medical profession, the world would be freed from that dreaded bacillus. The doctors, and the suffering and the dying all around the world held their breath (so to speak) believing that this announcement would be followed in a few, a very few, hours by the free gift of a full-working formula for this sovereign remedy, this salvation for the white-plague stricken world; and how was it given? Oh, a syndicate of capitalists was organized to see that the remedy was properly and safely concocted, and a protective tariff assessed, so as to protect us from a too lavish and wasteful use of a good thing, and, unintentionally, protected us from being seriously duped. Well, it died in borning, or soon after.

But not to be outdone, the progressive Yankee doctors, together with the State board of health, get out their microscopes and proceed to get wise, and soon run the root of this plague to earth, finding it in the poor, generous, patient and long-suffering cow, and they hasten to assure us that ninety per cent of all our dairy cows are so badly diseased that it was a divine miracle that any of us lived after having used butter, cream or milk, or even looked a fine, fat heifer in the face evening and morning at milking time. A generous anti-plague appropriation was secured, and an active professional campaign of education, and tubercular eradication was inaugurated, and the dear public were soon enlightened and taught that anything from a boil to a stone-bruise might be, or become, tubercular. Many herds of fine-bred, well-kept, fat and seemingly sound cattle, were condemned and ruthlessly slaughtered, and had it not been that the appropriation ran out, the great State of Illinois, in place of being a banner State for dairy products and beef cattle, would now be millions to the bad, and cattleless; and here endeth the second reading or lesson.

But the generous, self-sacrificing syndicate of professional knaves were not yet done with us, and operating through this same State board of health (how big that sounds) appointed through professional superiority or fitness? Oh, no; through political pull, have gotten another appropriation, and all over the States are to be seen the white tents of the isolated aggregation of white-plague smitten dupes; super nutrition for a time offsetting concentration of infection and depressing environment, and for a time inspires a hope for betterment, and thus the game is played, and will continue so long as the appropriation lasts, or able clients pay fat bills for fresh air. When, like in the case of the cow, it will become ancient history, and some new life-saving philanthropic fad must be devised and foisted on the gullible public. But what are the odds whether you die from open-air treatment or Christian Science, so long as you are hopeful and happy, and there still flows a stream of shekels from your pocket to pay the fiddler.

[Written for the MEDICAL BRIEF.]

Influenza and Intermittent Fever.

BY JOSEPH D. HARRIGAN, M. D.,
New York City.

NO. II.

Continuing the comparison, commenced in the June issue of the BRIEF, of the symptoms of these two diseases, we come to the consideration of those pertaining to the changes in the liver and the spleen.

Quoting from Professor O. Lichtenstern (Nothnagel's Encyclopedia, American Edition, page 668), on influenza, we find the following:

"As regards influenzal hepatic disease, the reports are mainly pathologic. Hyperemic conditions, parenchymatous degenerations, cloudy swelling, small-celled infiltration, microscopic tissue necrosis and formation of thrombus are mentioned."

The conditions for the formation of abscess of the liver, of which Kraunholtz and Cimbali have observed a case, are present in the severe forms of hemorrhagic-ulcerative enteritis.

Reynal describes a case of "icterus gravis" after influenza.

Experiences concerning the frequency of icterus in influenza are very varied.

It is mentioned by Lancisci (1709), and by Huxham (1737), as an occasional occurrence—"some fell into jaundice"—as well as by many later authors (Stoll, 1775, and others).

Peacock, in his description of the epidemic of 1847-48, remarked that "a frequent symptom was a feeling of heaviness and pain in the right hypochondrium, which was generally combined with a certain amount of icteric discoloration of the conjunctivæ or the skin in general."

Raeumler observed in the last pandemic: "Icterus, or at least icteric, discoloration of the sclera in 88.5 in males and 76.8 per cent in females;" that is, practically, always.

Rota (Bamberg) and Bergmann (Pottenstein) saw "numerous cases of icteroid discoloration of the conjunctiva and skin, as well as marked catarrhal jaundice," and the medical officer for the district of Merseburg reports, as the result of information supplied by the physicians of his district, that "in all the febrile cases, whatever the form of the disease, there was slight jaundice of the skin and eyes, as well as bile-pigment in the urine."

One feels tempted almost, after reading the description above of icteroid influenza, or, rather, of influenzic icterus, to wander into the domain of yellow fever and compare it with influenza, but—"sufficient to the day is the evil thereof"—the comparison will keep.

Passing to intermittent fever we find in the simple type, according to Mertz (Ziemssen's Cyclopedia, volume II): " * * * the skin is generally hot and dry, the complexion pale and muddy; growing yellowish and slightly icteric about the sixth to the eighth day."

And in the masked intermittents the same author says: "Masked fevers may, furthermore, manifest themselves in the form of intermittent hyperemia, hemorrhage, edema and inflammatory disturbances of nutrition. Among the latter are * * * swelling * * * of the liver * * * "

"* * * Intermittent jaundice also is sometimes encountered. During the year 1859 Martin saw a whole epidemic of intermittent jaundice, of the tertian type, among the French garrison at Pavia. On the fever days, the spleen and liver being swollen, the discomfort was greater, and the urine, conjunctiva and skin were darker-colored than on the days that were fever free * * * "

Coming to a consideration of the pernicious forms of intermittent, the same author says:

"It remains for us to notice the *icteric* form of malarial fever. It is usually developed from a simple intermittent, and prevails endemically in certain localities, as on the Island of Madagascar and on Nodso Bè. It often seems to give certain warnings of its approach, twelve to twenty-four hours in advance, such as headache, nausea, chilliness, and sometimes a slight icteric coloring of the conjunctiva or of the alæ of the nose. The actual attack always begins with a violent, long-continued chill, during which the icteric color either first begins, or, if already present, grows more intense, spreads over the entire body, and soon assumes a saffron or olive hue. Intense nausea is

now felt, with copious vomiting of bile, and often bilious diarrhea."

Pathologically considered, the author states that "the liver is often enlarged, in acute cases hyperemic, the parenchyma swollen and soft; sometimes, especially in the pernicious fevers of the tropics, it is studded with numerous apoplectic spots, or with disseminated and confluent inflammatory and purulent collections. In the icteric form the organ is very large, the gall-bladder usually filled with thick, dark-brown bile."

All that is stated here concerning the changes wrought in the liver in intermittent fever, together with the symptoms indicative of them, can be reiterated most emphatically of identically the same manifestations and conditions found in influenza. The only distinction (without a difference) is that arising from the varying degrees of concentration, and, possibly, also, of intensity of the poison factor in the matter. This, together with the varying extrinsic circumstances of purely chemical and electro-chemical environments, that go by the name of climate, constitute factors powerful enough, withal, to work certain changes in the accidentals of epidemic disease, modifying some, distorting others, but never eradicating the essentials that form the ground-work and frame-work upon which all depend.

Passing to the spleen in intermittent fever we find the same congestive and inflammatory developments that characterize the changes just now depicted as occurring in the liver. Hertz says:

"In most cases of pernicious intermittent, the *spleen* is enlarged, reaching three or four times its normal size. It is hyperemic and softened, sometimes consisting of nothing but a sac filled with a black, bloody fluid.

"Infarctions are not very rare, which may result in gangrene or the formation of abscess (cases reported by Scholz, Duchek and myself), and rupture of the spleen, with fatal hemorrhage into the cavity of the abdomen, may occur.

"It is not uncommon to find discolorations and thickening of the capsule of the spleen, and adhesions to neighboring organs.

"Under some circumstances, when death occurred during the first or second attack, the spleen has been found unchanged, this condition being particularly observed by Girard in the malignant fevers prevalent at Rome. * * *

"The 'ague cakes,' with which every one has long been familiar, are the results of frequent relapses of intermittent fever, lasting for a long time, and of primary chronic infection of a high grade. They consist of firm, tough, slaty tumors, presenting a smooth surface on section, rich in pigment matter, of enormous size; often fifteen or sixteen times the natural size of the organ, of the shape of a cake, usually provided with a thickened capsule, and attached by adhesions to the surrounding parts or organs.

"They represent either simple, hyperplastic conditions or amyloid degeneration. Leucemic tumors of the spleen seem to be of more rare occurrence, inasmuch as not a single case of the kind fell under my observation in Holland during six years; and Tomasi, during four years, within which time he saw very many tumors of the spleen, could never demonstrate any one of them to be leucemic. Occasionally the spleen may diminish in size again after having been enlarged; in that case it is firm, tough and atrophic, with a large increase of its trabecular tissue, and almost entire disappearance of its pulp."

With regard to the symptoms accompanying the pathological conditions noted, Hertz says:

"Tenderness and actual spontaneous pain in the spleen, or pain on taking a deep inspiration, or on coughing, sneezing, moving the body vigorously, or producing pressure over the organ, together with enlargement of the same, are phenomena worthy of attention in malarial fever. Duboue and Derblich, however, are mistaken when they represent the first symptom as being seldom absent, and regard it as of great diagnostic value, inasmuch as in many cases it may be sought for in vain, especially in all those of a chronic character. It arises from the great and rapid stretching of the spleen during the paroxysm, and is to be found, above all, in children and young persons during acute attacks, being less noticeable

in older persons, with thicker capsules that are not so easily distended. When the spleen has, furthermore, formed adhesions to neighboring organs, tenderness in this region, on moving or shaking the body, may remain persistent.

"Enlargement of the spleen from the most insignificant to the most formidable in degree, is a far more constant condition. If the enlargement is not great, the diagnosis must be made by means of percussion, as the tumor does not extend below the margin of the ribs. In more serious enlargements, however, the organ extends, to a greater or less degree, into the cavity of the abdomen, occupies a more vertical position, and may fill a great portion of the left side of this cavity. * * * Swelling of the spleen is even found in the new-born infants of mothers suffering from malarial fever. In ordinary intermittent fever the enlargement sometimes takes place as early as during the prodromal stage; usually, however, not until the stages of chill and heat, receding again during the sweat and the period of apyrexia. * * * The very evident and almost constant way in which the spleen is involved in intermittent fever, suggests the idea that the two are very nearly related. With our present knowledge we can no longer attribute the swelling of the spleen to an over-filling of the organ with blood during a chill alone, as it may attain to the very largest size in chronic infection without chills. Piorry reverses the old proposition, and designates intermittent fever as a result of disease of the spleen; Meckel and Duchek also declare the spleen to be the primary seat of disease.

"On the other hand, again, according to the reports of Jacquot, Saurier and others, people are said to die of malarial fever in Africa without the slightest swelling of the spleen. A singular case is also related in which a man received an extensive wound of the wall of the abdomen on the left side, through which the spleen escaped; as it could not be returned, it had to be removed. The patient recovered from the operation, and had malarial fever afterwards, just the same as before, although eventually a *post-mortem* examination showed nothing but the shriveled rudiment of a spleen left."

Passing now to consider the spleen in influenza, we find, according to Professor O. Leichtenstern, in Nothnagel's Encyclopedia (malaria, influenza and dengue, p. 669):

"In influenza, as a rule, the spleen is but rarely so much increased in size that a distinct enlargement can be demonstrated at the bedside. This applies particularly to the immense majority of mild cases. But in severe cases (about fifteen to twenty per cent), influenza, simple, as well as that with complications, gives rise to definite splenic enlargement, which can be determined with certainty during life, and whose existence is frequently confirmed at the *post-mortem* examinations. But the statements regarding the condition of the spleen in influenza are remarkably contradictory."

While the pathologists, Birch-Hirschfeld, "generally found no changes in the spleen," and Jürgens "had seen no splenic tumor," Ribbert, on the other hand, found "the spleen occasionally enlarged to several times its ordinary volume, and in all (eight) some enlargement."

In agreement with this author and other pathologists (Wallis), we, too, occasionally observed marked increase in the size of the spleen in a number of *post-mortem* examinations; so, too, Drasche found "in all influenzic cadavers, acute, and sometimes considerable enlargement of the spleen," while Winowgradow found it only twice in thirteen autopsies.

Kuskow found it enlarged twelve times among forty autopsies, generally but slightly; in the remaining twenty-eight cases the spleen was smaller, and "often considerably less in size."

After enumerating many authors and observers whose results of observation were on the negative side as to enlargements, the same author states:

"In marked contrast to these statements are numerous others, according to which the influenzic splenomegaly is of very frequent occurrence.

"Sokolow and Kernig describe enlargements of the spleen as a constant feature. It was observed in the city hospital at Dresden in 80 per cent of the cases; in Hamburg in 56 per cent; by Baumler (Freiberg) in 63.5 per cent, and by Schnaubert (Petersburg) in 39 per cent.

Goll (Zurich) describes it of very frequent occurrence. Guggenheim (Wurtzburg), in 25 per cent; Anton (Wurtzburg), in 16 per cent; Aufrecht in 20 per cent. We have found it in 14 per cent; Gutmann (Nuremburg), in 11 per cent; Krehl and Fischer in 10 per cent.

"In the French republic the frequency of enlargements of the spleen is almost invariably mentioned by Potain, Chantemesse, Guyot, G. Sée and Mangoubi."

We might thus continue indefinitely comparing the symptomatic and pathologic facts relative to these two diseases, and it would not be at all extravagant to claim that for one and all in the one case we would find duplicates in the other. But a sufficient number of points has, it seems to the writer, been offered proving indisputably that the essentials of these diseases are identical.

What really clouds the whole matter, as stated by me time and again, is the promiscuous, indiscriminate and unwarranted use of the word "complications."

A disease may have all the symptoms, almost to a dot, of another, and be considered as an entirely different affection, simply because of the greater or less prominence of one or two of the pathological developments occurring in the one case as compared with the other.

Thus, for instance, in a group made up of, say, for example, coryza, bronchitis, laryngitis, esophagitis, enteritis, hepatitis, nephritis and splenitis, should the bronchial symptoms seemingly be predominant, we call that group of symptoms, perhaps, influenza, "complicated" by splenitis, nephritis, etc., but should the enteritis, splenitis, etc., hold principal place, we may refer to the group as, if you please, malaria, "complicated" by bronchitis, laryngitis, pneumonitis, etc.

This is anything but scientific.

When we consider the wide variations in the symptoms of these two diseases, in different epidemics, and even in the same epidemic, it is ridiculously absurd.

It would seem to me far more scientific to take the simplest forms under which these different groups of symptoms occur, and from these simplest forms of epidemic disease, work our way forward towards the more complex, eventually advancing —without eliminating these simplest forms, but rather absorbing and utilizing them, to the most complex varieties under which epidemic disease manifests itself.

In other words, the most complex and deadly forms of epidemic disease contain within them all the essentials that go to make up the less complex and less deadly, down to the simplest and most trivial. Thus the plague, black death, etc., have, as part of their composition, *malaria* and its simplest progenitor, *influenza*. The whole scheme of epidemic disease is analogous to that of the science of mathematics, a building up, if you might say it, from primary principles.

Just as in the latter, the most complex operations have, intimately bound up in their intricacies, the simplest forms of arithmetical expression, so, in the former, the greatest combinations of symptomatic and pathologic phenomena, contain as a *sine qua non*, most easily understood, simple essentials.

Applying this theory to the two diseases under consideration, we would expect to find, from the perfect similarity of nearly all the symptoms present, and from the agreement of the pathological findings, either the two diseases to be identically the same, or else that one was a simplified form of the other. This would be in line with the differences existing between the malaria of stagnant fresh-water marshes and that caused by the salt-water marsh exhalation. It is a well-known fact that the latter form is the more severe of the two. That would bring in the point that, if the former is caused by the exhalations of carburetted hydrogen, the latter must have entering into its causation some other form of hydrogen—possibly chlorinated—from the decomposition of the chloride of sodium.

Thus we would have simple malaria, due to carburetted hydrogen; salt-water malaria due to the same+chlorine, or, possibly, chlorinated hydrogen alone; pernicious malaria, due to some similar form of hydrogen+environment, chemicals, etc., etc.

Now, if influenza and malaria are identically the same, only differing in degree of severity and extent of pathological changes, we must expect to find an etiological factor of very close kinship in the

former to that responsible for the latter disease.

In fact, we would expect to find some other combination of hydrogen, perhaps ammoniated.

How it is possible for the atmosphere of the earth to become surcharged with hydrogen, and thus, entering into combination with the ammonia, or other constituents found therein, to produce the widespread disturbances to health that are identical almost with malaria, and known to us by the name of influenza, it will be necessary to leave to a future paper for consideration.

[Written for the MEDICAL BRIEF.]

Trichinosis.

BY J. W. MCCALL, M. D.,
Huntingdon, Tenn.

The following is a reprint of cases of trichinosis from the *State Board of Health Bulletin*, Nashville, Tenn., published in that journal March, 1886, page 113, with an interesting sequel of microscopical examination of muscular tissue of one of the patients:

"TRICHINOSIS IN CARROLL COUNTY.

"HUNTINGDON, TENN., March 26, 1886.

"*Dr. J. D. Plunket, President State Board of Health, Nashville, Tenn.:*

"DEAR SIR—As per request, I make the following report:

"On the 26th of December, 1885, I was called to see the family of Mr. James Espy, seven in number—father, mother, two daughters and three sons, ages ranging from eighteen to fifty-eight years—living three miles west of Huntingdon, on the farm of H. C. Townes, Esq., of this place. I found Mr. Espy, the father, confined to the bed with considerable fever, some edema of the face and some muscular soreness. He stated that he was taken sick, five days previous to my visit, with vertigo, nausea and vomiting and chilly sensations, followed with fever. He thought the attack was brought on by overwork in a clearing in a creek bottom close by. It being a prolific spot for the development of malaria, I diagnosed his case one of that character, and so directed the treatment. On the 30th, and nine days from the commencement of the sickness of the old gentleman and four from my first visit, I was called to see the family again, and, to my great astonishment, found them all sick but one, out of seven. I found, also, that the diagnosis in the first case was incorrect, and it was not until the next visit that I become fully satisfied, by the exclusion of other diseases, of what seemed to me to be the true nature of the disease in the family—trichinosis—the result of eating insufficiently-cooked sausage infested with trichina spiralis.

"They were attacked from the 20th to the 24th, but did not report their cases to me at my first visit on the 26th. Two were taken with nausea and vomiting, accompanied with diarrhea, the other three had uneasiness and uncomfortable sensations in the alimentary canal, unaccompanied with vomiting and diarrhea; unpleasant sensations and pain in the head, with vertigo, were common to all. The most prominent symptom present was the great edema of the face and eyes, with apparent conjunctivitis, soreness of the flexor muscles, and edema of the feet and legs, coming on from the sixth to the tenth day from the commencement of the disease.

"It is truly a strange spectacle to enter a house and find every member of the family presenting the appearance of having been in deadly conflict with some species of the genus vespa.

"The muscular soreness and edema were not altogether so great in the cases that had vomiting and diarrhea in the commencement as those that were free from it. The edema in the feet and legs was three or four days later in making its appearance than in the face and eyes. The calves of the legs, the posterior portion of the thighs, and the anterior aspect of the upper extremities, were involved. In fact, the flexor muscles generally seemed to be the preferred site of the little depredator.

"One of the cases, the mother, had extreme soreness of the abdominal muscles, and great edema in the hypogastric region, extending to the vulva, which has scarcely now, eighty-eight days from the

attack, resumed their natural condition. One of the patients had soreness in the extensor muscles, that was in a slight degree in the thigh. There was no soreness nor stiffness to be found in the muscles of the back, back of the neck, or extensor muscles of the upper extremities. One complained of slight pain in deglutition, but I was unable to determine whether it was muscular or soreness on the inside of the throat from the effect of cold. The deeper structure of the eyeball appeared to be tender on pressure. The pupils were generally slightly dilated. Fever was present in all, varying in degree from an inconsiderable pyrexia in the evening, in those of a milder form of the disease, to a marked and continued fever of a remittent typhoid type, if I may be allowed the expression, in the cases of graver character. The temperature, as far as noted, was 99° to 102° F.; circulation, ninety to one hundred and thirty per minute; respiration, slightly accelerated. I will just say here that the frequency of the action of the heart was noticed as a prominent symptom throughout the disease; and even now, at the eighty-eighth day from the attack, when the young men are able to plow, the pulse rate is ninety-six to ninety-eight. The tongue was more or less coated, varying in color and extent from a normal to a slightly abnormal light to a brown color, and having a longitudinal fissure in the center, or mesial line, and indentations on the edge at the point pressed against the teeth, conveying the idea that it, too, was edematous.

"By the usual test, the urine was found to contain no albumin, was highly colored and scant in quantity, until the approach of convalescence, at which time it resumed its natural color, with considerable excess over the normal amount discharged in health. It continued to flow freely until that apparently anasarcal edema of the lower extremities had quite subsided.

"It should have been stated before that the seventh and last one of the family, a daughter, was taken sick six or seven days after the first, the disease making its appearance as in the first case, though in a modified form. The edema of the eyes and face, soreness of the flexor muscles, followed by edema of the feet and legs, were not so marked; the symptoms were sufficiently prominent, however, to make the diagnosis clear and unmistakable.

"For three weeks two of the young men were unable to dress or undress themselves, the muscular soreness was so intense, nor were they able to turn themselves in bed without help; notwithstanding this, when once on their feet, they were able to walk around the room and sit up some every day.

"After the first few days their appetites were generally ravenous, occasionally alternating with nausea and vomiting; the most of which was, I believe, justly attributable to excess in eating and drinking. They were thirsty from beginning to complete convalescence. From about the twelfth to the twenty-second day of the disease there was but little change in the condition of the more violent cases, except the edema had measurably left the eyes and face, and had increased considerably in the feet and legs, and had extended to the hips. The milder cases I consider decidedly convalescent at this date.

"On the twenty-fourth day I visited my patients again, found three of them on the bed, the other four sitting around the fire, presenting a pitiable appearance, indeed. Pulse varying from ninety to one hundred and twenty-six per minute; temperature, 99° to 102° F. One had itching sensation in the skin, with a tendency to effloresce under pressure or friction. One complained of a sensation as though cold water was being sprinkled over the surface. The other five were exempt from skin trouble. Two had profuse perspiration; one of these two cases, a daughter, who has tuberculosis, was able to be up and attend to some housework, and was thought to be improving up to the time she was taken sick with the present disease. Her feet and legs were swollen to an enormous size, extending to the hips and lower portion of the abdomen, having every appearance, except the extreme tenderness, of a regular anasarcal effusion, clear and pitting on pressure. In this case the urinary secretion was not excessive in quantity in the convalescent

stage of the disease, as stated in the other cases. Free perspiration continued constantly, day and night, for six weeks, until the edema had entirely disappeared from the lower extremities. She is again improving from the lung trouble, and has resumed the use of codliver oil.

"The treatment was not founded upon any preconceived idea gleaned from the text-books on the subject. They have none, practically. It was founded upon a commonsense view that a disease resulting from a parasite must be treated, if treated properly, with a remedy that kills parasites—a parasiticide—and upon this theory the treatment was based.

"It is a well-known fact among medical men that sulphur and its numerous compounds stand at the head of the list of zymotic medicines, and having unbounded confidence in the efficacy of these remedies in the treatment of parasitic diseases, malaria not excepted, I determined to select one of these compounds, and give it a thorough trial in these cases. The patients were all put on five-grain doses of the sulphite of soda in solution, every four hours, with direction not to disturb their rest during the night to administer the medicine. This treatment, and this alone, was continued from three to five weeks, or until the commencement of convalescence, at which time it was gradually withdrawn. The improvement was slow, especially so in the more violent cases. While all of the family, except the young lady with tuberculosis, are up and able to do some work, two of the young men are not yet able to mount a horse from the ground, because of the soreness and stiffness of the hips, and it is now eighty-eight days since the attack.

"I attribute the recovery of this family to the application of the proper remedy to the special pathological condition of the cases, the timely and constant use of the sulphite of soda, or, in other words, to the soluble sulphur contained in the compound, killing the young trichinæ, not only in their embryonic or infantile stage by coming in actual contact with them while in the alimentary canal, but by meeting them in childhood in their transit to and after their arrival at their distant muscular home.

"On receiving the report from the State Board of Health of the examination and finding of trichinæ in Nos. 4 and 10 of the eighteen suspected specimens of pork sent to Nashville, I went to Mr. Espy's, and compared these numbers with those on the different pieces of meat which I numbered at the time the specimens were cut out, and found them to be the hams of the hog whose history and pedigree is here appended.

"An investigation of the history of this hog developed the following facts:

"She was raised in Carroll County. For the first six or eight months she lived in the horse lot, around the corn crib and stables, afterwards she ranged in the creek bottom mostly. She was kept for breeding purposes, and was four years old when killed. In January, 1885, she had pigs, and after a week or two they all died, dropping off one at a time. Shortly after this she became very poor, so much so that Mr. Espy thought she had cholera, but did not know as to that positively. After a time, she improved in flesh, and in April, 1885, she was spayed, and was, to all appearances, as healthy as any one of the herd, and when put up to fatten, gained flesh as rapidly as any of the hogs with which she was penned. Mr. Espy slaughtered her the 15th of December, 1885, but observed nothing unusual in the meat.

"She was one-half Jersey Red, a very large, bony breed of hogs; the other side was Berkshire and Poland-China. A. G. Hawkins, Esq., of this place, bought her grand sire, a Jersey Red hog, from Thomas S. Grundy, of Springfield, Ky., seven or eight years ago. I am, sir,

"Very respectfully yours,

"J. W. McCall, M. D."

The foregoing reproduction of the report of seven cases of trichinosis treated successfully in the Espy family, in 1886, with the view of connecting that report with the sequel twenty-one years afterwards, which follows:

I am now, March 15, 1907, able to report the result (a confirmatory proof of correct diagnosis) of a microscopic examination made by Dr. Wm. Litterer, Professor of Pathology, Medical Department, Vanderbilt University, Nashville, Tenn.,

on the 11th of March, 1907, of muscular tissues taken from the gastrochnemius and biceps flexor cubiteus of the old gentleman of the Espy family twelve hours after his death, which occurred March 2, 1907, from a stroke of paralysis, age eighty-three years.

I selected the specimen for examination from the flexor muscles from the fact that they seemed to be the main seat of the disease, judging from the amount of soreness present at the time of their sickness. To verify this fact specimens of muscular tissue from the quadriceps femoris were also submitted to examination under the

microscope. An abundance of trichinæ were found in the three specimens examined, incapsuled in a cyst and calcareous shell, where they have been in a dormant state over twenty-one years, and now ready to pass through another cycle of life if favorably located in the stomach of some living animal, the secretions of which digest the cyst and dissolve the limey shell, and give vitality and growth to its occupants when set at liberty. (See plate.)

The subject of trichinosis should interest every one. It is a very fatal disease and easily prevented. It has doubtless

with like results, proving, beyond
that trichina spiralis can be transm

indefinitely from muscle to intestine, and from intestine to muscle *ad infinitum*.

When trichinæ have been domiciled in the muscular tissue for a number of years, it is not so easy to determine their identity, as the cyst enclosing the worm has, by this time, an earthy crust deposited within, which is said to be phosphate of lime.

When infected meat in this state is taken into the stomach, the cyst and calcareous deposit enclosing the trichinæ are digested and dissolved by the secretions of the stomach, and by the time the worm reaches the duodenum it is divested of cyst and earthy capsule. The intestines are now found to be crowded with the late arrivals of trichinæ from the stomach, and in five or six days they have reached adult size and age in the small intestines; the male is one-eighteenth and the female is one-eighth of an inch long, and they are copulating.

Trichinæ are viviparous, and in three or four days the female is giving birth to her brood, numbering from three hundred to two thousand young, active trichinæ in the small intestines, measuring in length from one one-hundred and fortieth to one one-hundred and twentieth of an inch. But little delay is made after their birth in penetrating the walls of the bowels, causing great irritation, pain and soreness of the bowels, nausea and diarrhea.

In their transit from the alimentary canal to their muscular home there is but little change in their size and shape.

How the young trichinæ get from the alimentary canal to the distant voluntary muscles, and in what issues they are domiciled after their arrival, are mooted questions. One thing is sure, they make a safe journey to the most distant voluntary muscles in the system, whether through the circulation of the blood, as some contend, having the ability to penetrate the walls of the blood vessels, the same as the intestinal walls, or make a slow trip through the flesh, after passing through the walls of the intestine. The latter position is strongly supported by the amount of soreness and edema of the entire body being traumatized by their passage through the tissues.

After eating meat infected with trichinæ the symptoms appear from two to four days, sometimes as late as the seventh day—sick stomach, pain and soreness in the bowels, with diarrhea; the more violent the diarrhea in the early stage of the attack the more favorable is the prognosis, as a general thing. On the contrary, if the diarrhea is slight or wanting, it gives the trichinæ time to penetrate the walls of the bowels and make their escape. There is often vertigo and headache. Later, there is general soreness and swelling of the entire body. The soreness and edema of the whole muscular system, simulating muscular rheumatism, is calculated to mislead the unsuspecting in diagnosis. Usually the pulse is rapid, skin hot and dry; in some cases, however, the skin is moist throughout the attack. Temperature ranges from 100° to 104° F., owing to the amount of lesion or irritation present in each case. In protracted cases typhoid symptoms may supervene. Difficulty in deglutition is present in some cases.

From ten days to three weeks is considered the critical period of the disease. If the disease has been diagnosed early in the attack, the very best thing to do is to administer a brisk cathartic, combined with a parasiticide, say thymol, to cripple or kill the parasites, and rush them out of the alimentary canal at once, giving them no time to commence their operation of boring through the walls of the bowels, and making their escape.

If the nature of the case has not been diagnosed in the early stage of the disease, or until, possibly, the trichinæ have passed through the walls of the bowels, drastic purgation is contraindicated; a parasiticide or antiseptic should be given throughout the attack. The bowels should be kept open in the latter stage of the disease with castor oil, to clear out the ptomains and putrescent debris of the alimentary canal. If there be prostration, debility or any other intercurrent trouble, treat as in other cases of like condition. There is no prophylactic, except through cooking of the meat we eat at a temperature of 212° F.

The host of trichina spiralis is the rat. It is said that about two per cent of the hogs that are slaughtered are infected.

All dead carniverous animals and fowls should be cremated.

The mother trichina, after giving birth to her numerous progeny, dies and passes off in the feces, accompanied by her male companion.

The abode of this parasite, after reaching the voluntary muscles, is a fusiform tube, lying among the muscular fibers, having the contour of what might be a degenerated muscular fiber, and, in all probability, is.

The habitat of the young trichinæ is the voluntary muscles only. They are never found in any other tissue of the body, and, invariably, breed in the alimentary canal.

A patient who has had trichinosis and recovered has never been known to have any trouble afterwards attributed to that disease.

I have been Mr. Espy's family physician for over forty years, and have not at any time detected any trouble since the attack of trichinosis in any member of the family that would lead me to even suspect the dormant trichinæ as being the cause.

[Written for the MEDICAL BRIEF.]

Organic Veil.

BY B. P. WATTS, M. D.,
E. Galesburg, Ill.

I have been in the practice of medicine thirty-five years, and have attended something over two thousand cases of obstetrics, and have so far failed to find what is denominated organic veil; however, my daughter, who has been in practice but three years, came in last evening with a perfect veil obtained from a little girl baby born on that occasion. Dr. Randelson, an old physician of this place, has one, the only one he was lucky enough to meet with in almost fifty years' practice, and, strange to say, the veil he has was taken from the face of an uncle (now eleven years old) of this little lady that was born yesterday, and from whom my daughter obtained the veil she has. Is there any heredity in this, or is it purely accidental?

What do the many brethren say?

[Written for the MEDICAL BRIEF.]

The Preventive and Curative Diseases of Babies and Children, with Dietetic Suggestions in Health and Sickness.

BY ELLA A. JENNINGS, M. D.,
Brooklyn, N. Y.

Every busy physician is greatly perplexed by the severe sickness of young children.

They can diagnose all right, but the prognosis don't always come out as expected.

Children have a way of converting hopeful into hopeless cases, in the shortest possible space of time; but it is equally true that apparently hopeless cases can as speedily change to resolution.

I have sat by the bedside of babies where it seemed impossible that they could live for an hour, and in two hours they were out of danger.

Babies are very susceptible to magnetism, and the suggestion of those about them. Often it is necessary to exclude a weeping mother, who can not control herself, and substitute a trained nurse, or some one who has self-control.

Babies do a great deal of thinking; they are so natural they get at the truth of things. My own baby girl, before two years old, often said: "I tant tell why, mover, but I feel it's so."

Very young children manifest repugnance or attraction, and their feelings should always be respected.

My own baby never cared for her wet nurse, a really beautiful Swedish young married woman, but would take the breast and turn her face toward me, and as soon as done nursing plainly indicate she wished me to take her.

Children are greatly injured by enforced association with one they dislike; their nerves are affected, their sweetness of nature destroyed, made irritable, unhappy and unbearable by this disagreeable association.

Some day we shall understand these subtle laws of nature, and then no child will suffer as now, through the law of attraction or repulsion.

The most impressionable period in a child's life is before birth, when the mother holds the child's future entirely in her keeping, especially in the last three months of its intra-uterine existence. When parents realize this truth they will become the architects of their children's lives, and permit no injurious influence to affect their unborn child. Then superior children will become the rule, instead of, as now, the exception.

When consulted professionally as to children's peculiarities, and those undesirable traits that appeared at an early age, by careful questioning of the mother I have elicited the condition she was in while carrying her little one, and she could generally account for the objectionable qualities, though greatly surprised that her state of mind during pregnancy should affect her child.

It is best to put only such traits in our little ones as we desire to see reproduced in them after birth. "As we sow we shall reap."

A busy physician has so little time to teach these truths, he is so occupied endeavoring to restore harmony to the diseased organism, that he seldom discusses the real cause of the trouble, but treats effects.

Prevention is so much better than cure, and some day we physicians will so regard it.

A child's food, both that received from the mother's breast and, later, at the table, has a profound effect upon its mental, moral and physical nature.

Babies and their diseases are the peculiar province of the woman physician. All her maternal nature is called forth at the sight of a sick child. She feels as if it were her very own precious little one, and she puts forth her best efforts and medical skill to save this child. She spares no pains, considers no sacrifice of personal comfort too great, nor refrains from making numerous (gratuitous, if necessary) visits in her desire to save the little one's life. She adds affection to skill, interest and tenderness to knowledge.

My dear brothers, you are welcome to carry off the honors in surgery, but when it comes to obstetrics and babies we women are at home, in the house of our nativity.

Men and women are not rivals, but complements to each other. The poet Tennyson expresses this much better than I can in his "Princess:"

"For woman is not undeveloped man,
But divine; not like to like, but like in difference."

We should work more together, each imparting a helpfulness the other needs. Our labors would bring greater fruits if we observed this method. Each lacks something the other can impart.

Comradeship in medicine would produce a much higher degree of attainment to both men and women.

Man excludes himself from blessings beyond estimate when he fails to take into partnership the women of his household.

Babies very early manifest a preference; little girl babies want to go to papa, while boys cuddle close to mother.

Oh nature, thou art a wonderful chemist and a profound teacher.

The soothing effect of an agreeable magnetism will change a cross, colicky baby, into a quiet, happy and comfortable child. Place the right hand upon the solar plexus of the little one, and the left hand on the occiput, or base of the brain, and in five minutes baby succumbs, and does not know what did it.

I have treated hundreds of cases in this way with unvaried success. Babies know who love them, and an unwelcome child suffers all through its life.

It is the greatest of crimes to bring an unloved child into the world, yet the majority of children are unexpected and undesired, hence the sorrow, trouble and disease that abounds.

Physicians have such golden opportunities to impart knowledge, to sow seed, to help their patients; they can so easily instruct—here a word, there a caution, and not tax themselves unduly. They can, while at the bedside, give valuable suggestions that will bear fruit.

Teach your patients that babies come from a warm temperature—98° F.—and need heat, air, water, food, cleanliness and tender handling. Keep your infants quiet the first three months of their lives. Do not let fond parents show off their little ones until the functions of life are

well established. It used to be thought that babies must have jaundice, but it is preventable by proper care and intelligent direction. Do not let baby be pinned up tightly; give her short dresses from birth, with knitted woolen shoes, so she can kick her feet and use her legs. The girl of the future is athletic from birth.

If this is done there will be less crying and less need of medicine.

All physicians know these simple facts, but in a busy life they do not have time to impress them; but, my dear brother physician, prevention is better than cure, and you have it in your power to accomplish so much good, not only in the present, but for future unborn generations.

Dr. Oliver W. Holmes said: "A child's training should begin three hundred years before it is born, but as the dear babies can not choose their ancestors, remote or near, will not you help the parents in your practice to more wisely choose, prepare for and provide the best conditions for their children that are to come?

The physician has both soul and body in his or her keeping, and it is a sacred stewardship, and we must account for our deeds of omission, as well as commission, in the discharge of our responsibility in the great work of producing superior progeny.

I ask your hearty co-operation in the building of a nobler race.

81 Columbia Heights.

The Relations of the Science of Chemistry to Medicine.

BY HOWELL B. GWIN, M. D.,

Nashville, Tenn.

Chemistry joins hands with medicine in the preparation of materials used by the practitioner.

Chemistry is the basis of pharmacy, which, in turn, is the basis of medical art. In the manufacture of all medicines how essential that the chemist's demands for exact proportions, pure materials, and orderly compounding, be scrupulously complied with, lest on both physician and patient injury be entailed.

Our science shows its value in pointing out compatibles and non-compatibles. Two recent instances of this much-needed knowledge have been pointed out to me. A physician was in the habit of administering, in rapid succession, doses of what are commonly called calomel and muriate of iron, without dreaming that corrosive sublimate was the product poisoning the stomach. A druggist displayed in his hand a prescription of a five years' practicing physician, which had been repeatedly sent for compounding, in which two ingredients neutralized each other.

The chemist aids the medicist by displaying the impurities of drugs and medicines used by him, and the merits and demerits of "patent medicines" which are unpopular with the profession.

He also wins our gratitude in bringing "Saratoga" and "Vichy" to our doors by his reproduction of their efficacy in the draughts we take from the apothecary's convenient fountain. Space allows but the suggestion of a few of the dictates of chemistry, concerning the administration of medicine: (1) That this be according to nature, in right order and quantity; (2) that long-kept compounds be scrupulously avoided, *e. g.*, the tincture of iodine may be decomposed with the formation of ioduretted ethers, and the spirit of nitrous ether becomes strongly acid and unfit for use; (3) that other cautions be taken, such as (*a*) preventing acids from contact with the teeth, and (*b*) requiring iodine tinctures to be applied with a camel's hair brush. Even in a mechanical way, chemistry furnishes glass, steel, alloyed utensils and instruments.

Chemistry is drawing closer to medicine in throwing light upon physical diagnosis. In the study of science two rules should be kept in sight.

The first, indorsed by Newton, expressed first by Aristotle, is, in the phraseology of later days, styled the "Law of Parsimony," or "Economy." Nature binds herself to the observance of this "law of parsimony" in three distinct lines of operation, (1) where an organ can be diverted from one and set to discharge another function, nature will spare herself the expense of forming a new organ, and will adapt the old one to a new use; prodigal in the variety of her adaptations, she is niggard in the invention of new structures; (2) where, by availing herself of

the inorganic forces always at work and available in the circumambient medium, wherever that medium may be, or where, by the employment, as in what is called "histological substitution," of a lowly organized or vitalized tissue, such as elastic tissue, she can spare herself the manufacture of such expensive structures as muscle, there nature adopts a line of practice which we term a "law of parsimony." (3) Where matter that would otherwise be wholly refuse, and rejected, can be utilized, there nature exemplifies her "utilization of waste substances." The air we use in speech could not be used in breathing.

The second enunciated by Descartes is, "We must omit none of the circumstances which can by any possibility be of the essence of the case." Some of the greatest advances in practical science have been and will be made in the spirit of this recommendation, such as a chemical test of the urine for information as to the expediency of giving or withholding wine in the case of a sinking life, which would have seemed to Swift more absurd than any of the follies he ascribed to the philosophers of Laputa. Could anything have seemed at first sight more impertinent, more otiosely curious and dilettante, than to inquire during an epidemic of cholera what was the nature of the subsoil in the area it was ravaging, to what depth it was porous, and at what level the water was, and had been previously, standing in it? And yet a distinguished German has won his battle on these points by fixing, "at Gibraltar and Malta the porous subsoil and the retreating ground-water as factors in the complex constituting an area or arena for cholera."

For the advancement of medicine we must look to an increased perfection of physical diagnosis, aided by pathology. The feelings of the patient, especially if many and varied, are not reliable, and need the interpretation of physical inquiry. The eye, ear, touch, and chemistry supplying the other two senses, are the physician's agents. Clinical medicine make at least two yet unsatisfied claims upon chemistry. We want (1) analysis of the residuum of the urine, in which we hope to discover new elements, and (2) ready clinical means for recognizing what has already been discovered by more elaborate process. Our hope in this direction is unlimited, seeing there must be changes in the organs and textures, whether healthy or morbid.

Chemistry may yet discover unknown causes of contagious diseases. It is not at all improbable that the theory of contagious disease that each owes its existence to a special living organism, and not to an organic poison, may ultimately prove to be correct; and, also, that a fever spread by infection or contagion can not originate spontaneously. Yet, in either case the physician, it is hoped, will be able to draw from the quiver of the chemist arrows that shall pierce the heart of the cause.

(To be continued.)

[Written for the MEDICAL BRIEF.]

Malarial Fever.

BY H. C. BUCK, M. D.,
Friars Point, Miss.

If one is guided by the accepted theories of to-day, the question naturally arises, What is malarial fever? In a work on practice, by Dunglison, published in 1842, the writer says: "The great exciting cause of intermittents is, doubtless, some emanation of whose nature we know nothing, which, under favorable circumstances, is exhaled from certain localities and not from others. The localities in which its effects are most observed are so generally marshy that the name marsh poison or marshy miasm has been given it. It does, undoubtedly, arise, however, in districts that are by no means paludal; and hence the Italian term malaria, which merely means 'bad air,' is a preferable term, and is generally adopted." In an article on "Malaria"* the writer says: "Malaria, in the widest acceptation of its meaning, signifies air which has been rendered so impure from any cause as to produce harmful effects on the human system."

Bartholow, 1895, in speaking of malarial fever, says: "The great etiological

*Dr. Charles Smart, Reference Hand Book, Medical Sciences, 1887.

factor is malaria;" he says, further, "Marshes or moist alluvium, subject to annual overflow and exposed to the action of the sun, by reason of evaporation or subsidence of the water, is peculiarly active in the production of the poison." Again he says, "That malaria is soluble in water, and is contained in the surface water of infected districts, seems now to be well established." In Hare's Practice, 1905, we find, "By malarial fever we refer to a condition produced by the entrance into and development in the blood of a specific micro-organism, known as plasmodium malaria, the hematozoon of malarial fever, or more correctly speaking, the hamameba malaria." Dr. William Krauss, of Memphis, Tenn., in an article, "Problems and Duties in Relation to Malaria,"* quotes from Thayer, "That malaria is only fever, more or less paroxysmal, divisible into three main varieties, each caused by a blood parasite." In answer to the question, What is malaria? Dr. Krauss says, "I answer that in the beginning it is an infection of the blood by one or more groups of one or more varieties of blood parasites, whose life function in the body is the destruction of hemoglobin." That malaria is fever, and often fever with a great big F, those of us who live in intensely malarial sections will promptly admit. I have just visited a patient, a young lady, with a temperature of 105° F., but does that answer the question? According to Dunglison, malaria means "bad air." If this is correct, then malarial fever is bad-air fever, or a pathological condition caused by inhaling bad air, or we should say the air in swampy, marshy localities during the summer or hot season of the year. If we admit this we are brought face to face with the mosquito theory, whose advocates claim the anopheles mosquito is the only means by which man can be infected with the malarial poison. Dr. Krauss says, "All practitioners know that in the spring malarias are paroxysmal, and as the season advances the recovery from an attack becomes less and less complete. In the spring a patient can take his quinine 'straight' and fare well, but toward the end of the season an ill-timed dose of quinine may produce grave consequences." As to the last assertion in the above, I have seen its truthfulness fully demonstrated, and as a result of my experience I make it a rule to begin my treatment of all cases of fever by thoroughly unloading the bowels and overcoming hepatic torpor. If the mosquito theory is correct, the term malarial fever is misleading, and should be abandoned. In deference to the advocates of this theory I would suggest the disease be called "anopheles fever," as we are taught man can only get the infection through the bite of the anopheles mosquito. All authorities, up to 1895, taught that the poison found entrance into the system through the air passages by breathing the air from marshes and through the intestinal tract by drinking surface or shallow well water in infected localities. Since the date above mentioned the mosquito theory has been almost universally accepted, and now all late authorities, seemingly, accept this theory in its entirety. Is it not possible that both theories are correct? In fact, I believe this is the case. While I believe the mosquito can and does convey the poison to the human, I believe this is not the only way by which it can reach the system. In an article,* "Pathogenesis and Prophylaxis of Malaria," "Kelsh does not deny the mosquito theory of the transmission of malarial infection," but he believes, "this does not exhaust all the possibilities of infection." He says, further, "Experience has too often demonstrated that epidemics of malaria follow the extensive turning up of the soil in excessively hot seasons, ingestion of dust-laden food, over-exertion, and other faults against hygiene; the distribution of the anopheles also does not always correspond to the distribution of malarial foci, and there can be no doubt that the hematozoon finds other ways to the body than in mosquito bites." In another article,† "Malaria in Greece," we find, "In several villages in Megalopolis malarial infection follows drinking water from a certain well. According to tradition and present-

* *Journal American Medical Association*, March 16, 1907.

* *Journal American Medical Association*, November 10, 1906.

† *Journal American Medical Association*, December 8, 1906.

day experience, when the people drink this water the spleen begins to enlarge and they have fever, while the symptoms vanish when they refrain from the use of the water." In still another article, "Transmission of Malaria."* "Plehn writes from Cameroon, Africa, that mosquitoes are rare there; prizes were offered for the anopheles, with fines for houses where specimens were found, but less than two dozen were encountered during a whole year, and yet he says nowhere throughout the world is there a more redoubtable focus of malaria than is that colony." Surely two dozen mosquitoes could not infect a whole colony, even if they were "hustlers from away back," and were ever so attentive to business. I am familiar with the arguments used by the advocates of the mosquito theory, but I do not see how one not blinded by prejudice or awe for so-called authorities, can overlook the instances quoted above; nor do I see how they can reconcile these facts and the teachings of late authorities. Many great truths have their origin from very humble sources, and I believe the day near at hand when there will be a modification or reversal of opinion as regards the mosquito theory in the propagation of malaria. Our motto should be, "Prove all things, hold fast that which is good."

Liberality in Medicine.

The following letters will serve to show that a more liberal feeling is growing in regard to the practice of medicine:

J. J. Lawrence, M. D., St. Louis, Mo.:

DEAR DOCTOR.—Will you allow me to express my appreciation, not only as it may apply to your estimable journal, THE MEDICAL BRIEF, but to you personally, for the sincere evidence of impartiality and true justice to all your readers. My expression of this regard is actuated by the instructive and highly intelligent articles that were communicated by Dr. Sisca, of Australia, on Homeopathy vs. Allopathy, in which a charity beneficence and just recognition was promulgated that should weld the two schools in a manner wholly to the good of humanity. I am a homeopathic practitioner, but to Dr. Sisca I can hold out my hand of fellowship with that regard for which true medicine alone should stand.

Fraternally,

W. F. ROTH, M. D.

Manheim, Pa., May 22, 1907.

(Dr. Roth is a graduate of Hahnemann Medical College and Hospital, Philadelphia, 1894).

J. J. Lawrence, Editor MEDICAL BRIEF:

DEAR DOCTOR.—I will have to subscribe for THE MEDICAL BRIEF again. I like its independence and liberalism. Inclosed find postoffice order for one dollar. Yours with best wishes.

C. S. WHITFORD, M. D.

Clarkston, Wash., May 12, 1907.

(By the way, I am an Eclectic-Bennett, 1882).

Editor MEDICAL BRIEF:

DEAR DR. LAWRENCE.—I am pleased to note the approved and splendid form of THE MEDICAL BRIEF, and to see that it conveys a feeling of liberality and truth. I can truly say that THE MEDICAL BRIEF is decidedly in advance of some years ago, when I received it, and the force and character of the journal reveals evidence of its being a journal second to none.

WM. R. WELCH, M. D.

Denver, Colo., January 26, 1907.

(Dr. Welch is Professor of Medical and Surgical Diseases of Women in the Denver Homeopathic Medical College).

[Written for the MEDICAL BRIEF.]

Venereal Diseases.

BY J. LEIBOVITZ, B. A., M. D.,
Newark N. J.

There can be no doubt but that the best and only treatment is by early excision of the initial lesion. My experience of this has been for many years, and in nine out of every ten cases, positive results have always been obtained. Of course the excision of the chancre should only be performed under the following circumstances:

1. When seen at its commencement.

---

* *Journal American Medical Association*, December 15, 1906.

2. Where the excision can be easily and carefully practiced and without any danger.

3. In cases not attended by adenopathy.

4. The patient should be free from diabetes.

Specific treatment should not be resorted to until such time as there are symptoms of the secondary stage, for then the diagnoses as to primary syphilis are not always easy. At the commencement, as to cases treated with mercury, show the later manifestations have not been more in one class than in the other. From one to two drachms of mercurial ointment should be applied for, say, fifteen days, then an interval of twelve days allowed, and this alternation carried out for some time. Protoiodide of mercury three times a day is very good, with iron and iodide of potassium in anemia.

The following prescription goes well, and medical men will do well to note it, as I have extensively used it in my practice:

℞ Hydr. Protoiodide ..... 1/8 grain.
Iodoform ..... 3/4 grain.
Ferri Sulphatis ..... 3/4 grain.
Ext. Opium ..... 1/12 grain.
Ext. Gentianæ ..... 1/12 grain.

M. Sufficient to make into one pill. D. T. D. No L. Sig.: To be taken one three times a day.

184 Spruce Street.

[Written for the MEDICAL BRIEF.]

Two Cases of Arthrogryposis.

BY ROCCO BELLANTONI, M. D.,

New York City.

This affection is commonly found among infants, and is frequently unknown because it rapidly disappears. Often the fingers of the baby's hands have been found contracted, and the physician sees nothing abnormal, and thinks he was mistaken in his ideas, yet these muscular contractions should be heeded in children, especially in infectious diseases, as diphtheria, scarlet fever, small-pox, pneumonia, etc., and in gastro-enteric disturbances they should give more thought to muscular contractions, as all diagnosticians will find this symptom in most all troubles.

There are times when the mother gives little attention to the febrile conditions of the baby, and do not call the doctor's attention to it. If the family physician paid more attention as to the possible cause, they would be justified in giving more research, and be persuaded that this disease should be classed as a special one, and have the symptoms and complications of other diseases, and should be so considered.

In the past month I have had two cases of this disease: One in a child of three years, who was suffering from a very grave diphtheria of the pharynx, with diffusion in the nasal fossa and tubes, and both internal and external ears. In such cases, where there were toxemic conditions, I saw on two occasions that the hands were contracted similar to that of the obstetrician when making obstetrical investigations, viz., all fingers extended and adjusted as a cone of the palmar muscles. This condition remained less than one day.

Other baby, eighteen months old, five days after weaning (the mother was pregnant) showed the same contractions of hands as former baby, which was his cousin. His forearms were flexed, as also his toes were in about the same condition.

He was suffering from laryngeal fever and constipation.

Nervous disturbances were very manifest in all the family, and verifies what Eichhorst has said in regard to this disease in relation to nervous neuroses.

I believe these cases worthy of mention in order to call attention of practitioners to a subject very frequently neglected.

I think that a large number of these troubles are not special diseases, but complications. Escherich says he believes an unique course produces it.

371 Broome Street.

Stolen Thoughts.

Read not to contradict and confute, nor to believe and take for granted, nor to find talk and discourse, but to weigh and consider. Some journals are to be tasted, others to be swallowed, and some few to be chewed and digested; i. e., some are to be read only in parts, others to be read but not curiously, and some few to be read wholly, and with diligence and attention.

Book Notices.

A CYCLOPEDIA OF PRACTICAL MEDICINE AND SURGERY. A Concise Reference Book, Alphabetically Arranged, of Medicine, Surgery, Obstetrics, Materia Medica, Therapeutics, and the Various Specialties, with Particular Reference to Diagnosis and Treatment. Compiled under the editorial supervision of George M. Gould, M. D., and Walter L. Pyle, M. D. Philadelphia: P. Blakiston's Son & Co. Price, $10.00.

As the caption of this work is suggestive of the contents, we will cite a list of names as contributors, some of which may appeal to you: Drs. Samuel W. Abbott, James M. Anders, Joseph D. Bryant, James B. Bullitt, Chas. H. Burnett, J. Abbott Cantrell, Archibald Church, L. Pierce Clark, Solomon Solis-Cohen, Nathan S. Davis, Jr., Theodore Diller, Augustus A. Eshner, J. T. Eskridge, J. McFadden Gaston, J. McFadden Gaston, Jr., Virgil P. Gibney, George M. Gould, W. A. Hardaway, John C. Hemmeter, Barton Cooke Hirst, Bayard Holmes, Orville Horwitz, Daniel E. Hughes, James Nevins Hyde, E. Fletcher Ingalls, Abraham Jacobi, William W. Johnston, Wyatt Johnston, Allen A. Jones, William W. Keen, Howard S. Kinne, Ernest Laplace, Benjamin Lee, Charles L. Leonard, James Hendrie Lloyd, J. W. McDonald, L. S. McMurtry, G. Hudson Makuen, Matthew D. Mann, Henry O. Marcy, Rudolph Matas, Joseph M. Mathews, John K. Mitchell, Harold N. Moyer, A. G. Nicholls, A. H. Ohmann-Dumesnil, William Osler, Samuel O. L. Patter, Walter L. Pyle, B. Alexander Randall, Joseph Ransohoff, Jay F. Schamberg, Nicholas Senn, Richard Slee, S. E. Solly, Edmond Souchon, Ward F. Sprenkel, Charles G. Stockton, John Madison Taylor, William S. Thayer, James Thorington, Martin B. Tinker, James Tyson, J. Hilton Waterman, H. A. West, J. William White, Reynold W. Wilcox, George Wilkins, DeForrest Willard, Alfred C. Wood, Horatio C. Wood, Albert Woldert, James K. Young. If the above list of contributors appeals to you you will know what to expect when you secure this work. It is a jewel for the active practitioner.

A MANUAL OF THE DIAGNOSIS AND TREATMENT OF THE DISEASES OF THE EYE. By Edward Jackson, A. M., M. D., Professor of Ophthalmology in the University of Colorado; Emeritus Professor of Diseases of the Eye in the Philadelphia Polyclinic; formerly Chairman of Section on Ophthalmology of the American Medical Association; ex-President of the American Academy of Medicine, and of the American Academy of Ophthalmology and Oto-Laryngology, and Member of the American Ophthalmological Society. Second edition, thoroughly revised. With one hundred and eighty-two illustrations and two colored plates. Philadelphia and London: W. B. Saunders Co. Price, $2.50.

As a work for the general practitioner and also for the systematic reading of the student, the newer methods of merit have been fully recognized in this edition. Such methods as: Testing the Light Sense, Mapping Central Scotoma, Taking the Prominence of the Eye-Ball and the "Fogging Method," the Account of the Mechanism of Accommodation and Pseudo-Accommodation, Special Uses of Lenses in the Ophthalmoscopic Examination, Changes in Refraction with Age, Amblyopia with Squint, the Treatment of Comitant Strabismus, Diseases and Congenital Defects of the Ocular Muscles, Putrefying Conjunctivitis, Special Conditions that Influence Keratitis and Its Treatment, Family Degeneration of the Cornea, Ureitis in Its General Relations, Theories of Sympathetic Ophthalmia, General Considerations Regarding Diseases of the Retina, Macular Atrophy of the Retina, etc. This resume of the contents of this book serves to show the reader the wide scope of its worth, which, for want of space, we have greatly curtailed. On ophthalmological scientific facts it is certainly a great work for practitioner, as well as student.

MEDICAL JURISPRUDENCE, FORENSIC MEDICINE AND TOXICOLOGY. By R. A. Witthaus, A. M., M. D., Professor of Chemistry, Physics and Toxicology in Cornell University, and Tracy C. Becker, A. B., LL. B., Counselor-at-Law, Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. With the collaboration of August Becker, Esq., A. L. Becker, Esq., Chas. A. Boston, Esq., Hon. Goodwin Brown, Hon. W. N. Bullard, M. D., J. C. Cameron, M. D., J. Clifton Edgar, M. D., Jas. Ewing, M. D., E. D. Fisher, M. D., J. C. Johnson, M. D., D. S. Lamb, M. D., H. P. Loomis, M. D., W. B. Outten, M. D., Roswell Park, M. D., J. Parmenter, M. D., Irving C. Rosse, M. D., E. V. Stoddard, M. D., George Woolsey, M. D., and J. H. Woodward, M. D. Second edition, Volume II. New York: William Wood & Co. Price, cloth, $6.00; sheep, $7.00.

This excellent work on medical jurisprudence will be completed in four volumes, and will make a complete library on this important subject. Vol. II. contains: Table of Cases, Forensic Medicine continued; Thanatological, continued, *i. e.*, Relating to Dead Bodies; Medico-Legal Consideration of all Wounds, Medico-Legal Relations of Electricity, Medico-Legal Consideration of Death from Mechanical Suffocation, Death from Submersion, Determination of Survivorship, Bio-Thanatological, *i. e.*, Relating to Both Dead and Living; Abortion and Infanticide, When Medical Examination of the Living is Permitted or Required by Courts of Law, Pregnancy, Labor, and the Puerperal State, Sexual Incapacity, Rape, Unnatural Crimes, Railway Injuries, and a Complete Index. This is certainly a very valuable work on the subject, and all physicians can consult this work and know the exact status of any case bearing on medico-legal relations, and who needs such a work more than the physician?

A TEXT-BOOK UPON THE PATHOGENIC BACTERIA. For students of medicine and physicians. By Joseph McFarland, M. D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College, Philadelphia, etc. Fifth edition, thoroughly revised. With one hundred and ninety illustrations, many of them in colors. Philadelphia and London: W. B. Saunders Co. Price, $3.50.

The author has profited by the reviews and suggestions made on former editions and incorporated such matter as seemed justifiable for its improvement, therefore the reader will find changes and some parts entirely rewritten.

THE PRACTITIONER'S LIBRARY OF GYNECOLOGY, OBSTETRICS AND PEDIATRICS, in Original Contributions, by Eminent American and English authors. THE PRACTICE OF GYNECOLOGY—Edited by J. Wesley Bovée, A. M., M. D., Professor of Clinical Gynecology in the George Washington University, Washington, D. C. Large octavo, eight hundred and thirty-six pages, with three hundred and eighty-two engravings and sixty full-page plates in colors and monochrome. THE PRACTICE OF OBSTETRICS—Edited by Reuben Peterson, A. B., M. D., Professor of Obstetrics and Diseases of Women in the University of Michigan, Department of Medicine and Surgery, Ann Arbor, Mich. Large octavo, one thousand and eighty-seven pages, with five hundred and twenty-three engravings and thirty full-page plates in colors and monochrome. THE PRACTICE OF PEDIATRICS—Edited by Walter Lester Carr, M. D., Consulting Physician to the French Hospital; Visiting Physician Infants' and Children's Hospital, New York. Large octavo, one thousand and fourteen pages, with one hundred and ninety-nine engravings and thirty-two full-page plates in colors and monochrome. Philadelphia: Lea Brothers & Co. Price, per single volume, cloth, $6.00; leather, $7.00; half morocco, $8.00. Price for any two volumes, cloth, $11.00; leather, $13.00; half morocco, $15.00. Price for the three volumes, cloth, $15.00; leather, $18.00; half morocco, $21.00.

What better addition could a practitioner make to his library than these three volumes, the subjects of which are so closely allied and yet so distinct in their bearings. What better authority can be found than these professors to edit such works? In preparing this new series the object has been to cover the whole domain composed of three cognate major specialties. Eminent American and English authors have united under the editorship of Drs. Bovee, of Washington; Carr, of New York, and Peterson, of Ann Arbor. By excluding those features of disease which are properly to be sought in works on general medicine, these volumes find space for a complete and comprehensive presentation of their respective subjects, with full, practical details. Together with the most advanced knowledge of established value, the authors have included their own observations, and the therapeutic measures which have resulted in the greatest success. This adds a personal element of obvious value. The engravings alone are rich in conception and significance. In conclusion, it is wise to say that every physician should have these three volumes in his library, but should he only desire any of them separately he can secure them at prices named above.

MODERN SURGERY. General and Operative. By J. Chalmers DaCosta, M. D., Professor of the Principles of Surgery and of Clinical Surgery in the Jefferson Medical College, Philadelphia; Surgeon to the Philadelphia Hospital, and Consulting Surgeon to St. Joseph's Hospital, Philadelphia. Fifth edition, thoroughly revised and enlarged. With eight hundred and seventy-two illustrations, some of them in colors. Philadelphia and London: W. B. Saunders Company. Price, cloth, $5.50; half morocco, $7.00.

If any physician or surgeon will glance at this edition they will find that the work has been thoroughly overhauled and many alterations and additions have been made. Especial note should be made on the subject of hernia, ulcer of the stomach, cancer of the stomach, ulcer of the duodenum, tetanus, snake bites, syphilis of bones and joints, gonorrhea in children, concussion of the brain, compression of the brain, hydrocephalus, cephalocele, spina bifida, suture of the divided spinal cord, injuries of electricity, fractures of the bones of the foot, surgical tuberculosis, cleft palate, Bier's method of congested hyperemia, and perforation of the bowel in typhoid fever. These subjects have been changed to conform to new methods, and much new matter, not in past editions, have been added, thus making this edition appear almost like a new work.

EYE INJURIES AND THEIR TREATMENT. By A. Maitland Ramsey, M. D., Fellow of Faculty of Physicians and Surgeons, Glasgow; Ophthalmic Surgeon, Glasgow Royal Infirmary; Professor of Ophthalmology, St. Mungo's College; Lecturer on Eye Diseases, Queen Margaret College, University of Glasgow; author of Atlas of External Diseases of the Eye, etc. Glasgow: James Maclehose & Sons, publishers. New York: The Macmillan Co. Price, $6.00.

The beauty and clinical worth of this work consists mainly in the colored plates and the excellence of the formulæ. Theoretical discussions find no place in this book, but the clinical facts that are mainly drawn from the personal experience of Dr. Ramsay will prove of inestimable worth to the reader. In case of accident the reader will find material that will serve as a safe guide. Many new features are incorporated that will make this book very valuable. General practitioners are interested in eye troubles.

PSYCHOLOGY APPLIED TO MEDICINE. Introductory Studies. By David W. Wells, M. D., Lecturer on Mental Physiology and Assistant in Ophthalmology, Boston University Medical School, etc. Philadelphia: F. A. Davis Co., publishers. Price, $1.50.

As a lecturer to medical students for many years this matter is presented as a step between psychology and medicine. The author thinks this subject should be opened up to the undergraduate at least in an elementary way, and in this work he aims to accomplish this, and, seemingly, does so in a systematic manner that seems to be convincing, as three chapters are especially devoted to hypnotism in an attempt to sum up the history, phenomena and theories. It would be well for all physicians to study this subject.

FOODS AND THEIR ADULTERATION. Origin, manufacture and Composition of Food Products: Description of Common Adulterations, Food Standards, and National Food Laws and Regulations. By Harvey W. Wiley, M. D., Ph. D. With eleven colored plates and eighty-six other illustrations. Philadelphia: P. Blakiston's Son & Co. Price, $4.00.

Dr. Wiley, as is well known, is the Chief of the Bureau of Chemistry in the Department of Agriculture of the United States Government at Washington, and of course has inside information regarding the subject on which he writes, therefore he expresses the law regarding the subject and must be correct in his statements. If you are interested in this subject it would be well to secure a copy of this work.

THE PRINCIPLES AND PRACTICE OF DERMATOLOGY. Designed for Students and Practitioners. By William Allen Pusey, A. M., M. D., Professor of Dermatology in the University of Illinois, Dermatologist to St. Luke's and Cook County Hospitals (Chicago), Member of the American Dermatological Association. With one colored plate and three hundred and sixty-seven text illustrations. New York and London: D. Appleton & Company. Price, $6.00.

There is no specialty in medicine that calls for a more practical and concise knowledge than diseases of the skin—what will relieve or cure one class is poison for another. Therefore it requires a thorough knowledge of the anatomy, physiology, general etiology, pathology, symptomatology, and, not less, the proper treatment. If the general practitioner undertakes the treatment of diseases of the skin he should be thoroughly posted in regard to the differential conditions, so he can intelligently treat them. If they are beyond his knowledge of diagnosis it would be best to consult one who has made dermatology his special study. A thorough reading of this work will pull him through many intricate cases. General treatment has been considered in full.

THE TREATMENT OF DISEASE. A Manual of Practical Medicine. By Reynold Webb Wilcox, M. A., M. D., LL. D., Professor of Medicine at the New York Post-Graduate Medical School and Hospital; Consulting Physician to the Nassau Hospital; Visiting Physician to St. Mark's Hospital, etc., etc. Philadelphia: P. Blakiston's Son & Co. Price, $6.00.

We believe that works on practical medicine, from authoritative sources, should command attention. Dr. Wilcox, with twenty-three years' experience, and more than ten thousand graduates—many of whom will see this notice—deserves a consideration that would be envied by many of less note. We all know that the active practitioner needs all the latest views on methods of diagnosis and treatment. The progressive and up-to-date practitioner has little time to pore over volumes in search of therapeutic knowledge, when he can secure the practical items in one volume, and gain the therapeutic knowledge—physical, medical or dietetic—at a glance, because the arrangement is perfect. This work is specially adapted to the *practical* needs of the physician. It is well worth the outlay.

LATERAL CURVATURE OF THE SPINE AND ROUND SHOULDERS. By Robert W. Lovett, M. D., Boston, Associate Surgeon to the Children's Hospital, Boston, etc. With one hundred and fifty-four illustrations. Philadelphia: P. Blakiston's Son & Co. Price, $1.75.

It has only been in later years that reliable data in relation to proper and successful treatment regarding curvatures of the spine has been successfully introduced, and it is certainly an innovation to have a work devoted especially to this subject. A great deal of progress has been made in late years in regard to what is best in such cases, especially children's, and a work of this nature becomes a necessity, if such corrections are needed to frame the human body as it was intended to be by nature. This work is worthy the consideration of any physician.

A SYSTEM OF MEDICINE. By Many Writers. Edited by Thomas Clifford Allbutt, M. A., M. D., LL. D., D. Sc., F. R. C. P., F. R. S., F. L. S., F. S. A., Regius Professor of Physic in the University of Cambridge, Fellow of Gonville and Caius College; and Humphrey Davy Rolleston, M. A., M. D., F. R. C. P., Physician to St. George's Hospital and to the Victoria Hospital for Children, sometime Fellow of St. John's College, Cambridge. Volume II., Parts 1 and 2. London and New York: Macmillan & Co., Limited. Price, per part, $5.00.

Since the first edition, in 1897, many changes have been made in methods of practice—ten years have been spent in fruitful endeavors, and these volumes have the benefit of being a new, rather than a revised, edition of this practice of medicine. The editors are certainly to be congratulated on this modern effort, as the past ten years have been productive in practical medicine. Allbutt's Practice has always been a standard, and now that it has been brought up to date, should find a ready sale among those physicians who know a good thing.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M. D., Professor of Nervous and Mental Diseases and Medical Jurisprudence in the Northwestern University Medical School (the Chicago Medical College), Chicago; and Frederick Peterson, M. D., President of the State Commission in Lunacy, New York; Clinical Professor of Neurology and Psychiatry, Columbia University. Fifth edition, revised and enlarged. With three hundred and forty-one illustrations. Philadelphia and London: W. B. Saunders Co. Price, cloth, $5.00; half morocco, $6.00.

In this edition the section on "Nervous Diseases" has been carefully taken into consideration and brought abreast with the present thought on the subject. So much discussion has been had, through expert evidence, on the subject of nervous and mental derangements that it would be well for all practitioners to more fully book themselves up on the subject. This book is in its fifth edition, and the fact must not be lost sight of that the authors are in positions to fully give the best matter on the subject. Do not fail to add this work to your library, as you do not know how soon you may have to refer to it.

THE COMMON BACTERIAL INFECTIONS OF THE DIGESTIVE TRACT, AND THE INTOXICATIONS ARISING FROM THEM. By C. A. Herter, M. D., Professor of Pharmacology and Therapeutics in Columbia University; Consulting Physician to the City Hospital, New York. New York and London: The Macmillan Co. Price, $1.50.

The author of this work presents his views to the Harvey Society for the diffusion of medical knowledge, and then says that his views are presented fully in this volume because they are not suited for publication in a medical journal, and yet wishes them to be investigated by practitioners. What more suitable place could he have had for discussion than the medical journal? The author lays great stress on the originality of the methods produced in his own private laboratory, therefore, this work must be exclusively the author's views and has originality—a rare thing in books nowadays—especially in medicine.

SURGICAL DIAGNOSIS. By Daniel N. Eisendrath, A. B., M. D., Adjunct Professor of Surgery in the Medical Department of the University of Illinois (College of Physicians and Surgeons); Attending Surgeon to the Michael Reese and Cook County Hospitals, Chicago. With four hundred and eighty-two original illustrations, fifteen of them in colors. Philadelphia and London: W. B. Saunders Company. Price, cloth, $6.50; half morocco, $8.00.

Diagnosis is certainly one of the most important considerations in medicine or surgery. To diagnose properly before giving medicines or using the knife is worthy of consideration. When proper consultation has been had and operation is the only means of relief, there is no reason why it should not be speedily done. This work should be carefully read, if any doubt exists as to the method of operation, or whether it had not been better to treat medicinally. A work of this nature should be read liberally and thoughtfully, especially regarding the differentiation of affections which simulate each other.

THE INTERNATIONAL MEDICAL ANNUAL. (A Year Book of Treatment and Practitioner's Index.) A Review of Therapeutic Progress in Medicine. New York: E. B. Treat & Co., publishers. Price, $3.00.

This is the twenty-fifth yearly issue of this work and shows that it is yet young and active and has grown larger by about seventy-four pages. As long as a work shows an advance in its make-up it deserves the recognition that has always been accorded it by the profession and demonstrates that its appreciation is deserved and the publishers can afford to continuously increase its value. If you are interested in cancer do not overlook, in this volume, the part which gives sixty original contributions and monographs, illustrated. Many new and valuable things are given. Do not overlook this annual.

A TEXT BOOK OF THE PRACTICE OF MEDICINE. By James M. Anders, M. D., Ph. D., LL. D., Professor of Medicine and Clinical Medicine at the Medico-Chirurgical College; Physician to the Medico-Chirurgical Hospital; formerly Physician to the Philadelphia and to the Protestant Episcopal Hospitals, Philadelphia; Fellow of the College of Physicians; Member of the Academy of Natural Sciences, Philadelphia, etc. Illustrated. Seventh edition. Thoroughly revised. Philadelphia and London: W. B. Saunders Company. Price, cloth, $5.50; sheep or half morocco, $6.50.

While the original plan of this work has been retained, the author has thoroughly revised it and brought the matter up to the latest in practice and diagnosis. It certainly is a compliment to the author to know that his efforts have been so highly appreciated by the press and practitioners.

ESSENTIALS OF PRESCRIPTION WRITING. By Bernard Fantus, M. D., Professor of Materia Medica and Therapeutics, College of Physicians and Surgeons of Chicago, the College of Medicine of the University of Illinois, Professor of Materia Medica and Therapeutics, Jenner Medical College. Chicago: Chicago Medical Book Co. Price, $1.00.

The preface of this work shows conclusively why it was issued, and by giving a synopsis of it we will aim to show just reason: "Shortly after the publication of the author's 'Text-Book on Prescription Writing and Pharmacy,' which includes practice in prescription writing and laboratory exercises in pharmacy, the demand arose for a book on prescription writing that would cover the essentials of prescription writing quite as fully as the book just mentioned, to be used by students who do not have the facilities for laboratory work, nor the help of a teacher in the working out of the problems in prescription writing." This is the meat without the bones. It will be a great aid.

ESSENTIALS OF CHEMISTRY AND TOXICOLOGY. For the use of Students in Medicine. By R. A. Witthaus, A. M., M. D., Professor of Chemistry, Physics and Toxicology in Cornell University. Thirteenth edition. Revised by R. J. E. Scott, M. A., B. C. L., M. D., author of "The State Board Examination Series." New York: William Wood & Co. Price, $1.00.

This work has been so popular with the American medical student that the thirteenth edition was earnestly called for. The celebrated author has used his utmost endeavors to place in the hands of the student a work that is relieved of all verbiage and included only the essential facts, especially that of the chemistry of therapeutics in preference to that of pharmacy, thus making it applicable for the foundation of rational medicine. Many changes have been made in this edition, and we find it up to the standard.

A TEXT BOOK OF MATERIA MEDICA, THERAPEUTICS AND PHARMACOLOGY. By George F. Butler, Ph. G., M. D., Associate Professor of Therapeutics in the College of Physicians and Surgeons, Chicago; Professor of Medicine and Therapeutics, Dearborn Medical College, Chicago. Fifth edition, thoroughly revised and rewritten, and adapted to the eighth revision (1905) of the U. S. Pharmacopeia. By Smith Ely Jelliffe, M. D., Ph. D., Professor of Pharmacognosy and Instructor in Materia Medica and Therapeutics in Columbia University (College of Physicians and Surgeons), New York. Philadelphia and London: W. B. Saunders Co. Price, cloth, $4.00; half morocco, $5.00.

This work should meet the demand of a new book on the above subject, as it has been entirely remodeled, rewritten, and all the type has been reset, thus making an entirely new and clean edition, although the work is not as bulky owing to its being more compact, thus a vast improvement in its style has been made at no sacrifice to its worth. In fact, it is an up-to-date work on materia medica and will appeal to all students and practitioners.

RETINOSCOPY (or shadow test). In the Determination of Refraction at One Meter Distance, with the Plane Mirror. By James Florington, A. M., M. D., author of "Refraction and How to Refract," "The Ophthalmoscope and How to Use It," Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine, etc. Fifth edition, revised and enlarged. Fifty-four illustrations, ten of which are colored. Philadelphia: P. Blakiston's Son & Co. Price, $1.00.

The simplest and best methods always commend themselves to thinkers, therefore to get out of the old ruts and read along new lines of thought can but be beneficial to any one who wishes to progress in his practice. This work will give you new ideas. Why not benefit by them?

Editorial.

Envy.

The envious man is never happy and rarely successful. He can not see clearly the relation of things because of the cloud over his faculties. He is so busy finding fault with others he can not find time to attend to his own affairs. Envy is a greater handicap to a man's efforts than a physical deformity. Envious thoughts act like a poisonous ferment, sickening and perverting the unfortunate being that harbors them. Emulation stimulates a man to stronger and better efforts, whereas envy only incites within him an animosity and rancor which, when expressed, excites in others distrust and disapproval rather than sympathy and support. The doctor, for instance, who starts out to crush a competitor by ridiculing him, by insinuating all manner of disparaging things, may set a town by the ears for a little while, but the truth is certain to be known sooner or later, and then his wrong-doing will recoil on his own head.

There are few doctors, we are glad to say, who would stoop to use such contemptible means of uplifting themselves. The great majority believe in a fair field and a straight race. Cordial relations and reciprocal good wishes are the rule.

This is the right way. The doctor, of all men, needs to study how to see the good in everything and everybody. He should strive constantly to broaden himself, to refrain from being governed by his prejudices, to keep from criticizing where there is no need for it. The more

manly the doctor is, the more he can do for others. The strong, helpful spirit brings a sustaining atmosphere into the sick-room. Rest and comfort penetrate like a healing balm straight to the citadel of life. The patient is better for the doctor's visit. How or why she hardly knows, but "virtue has gone out of him."

So do not get into the habit of grumbling and finding fault. Seek out the ever-present good, and dwell on that. Persons are seldom made better by harping on their faults. Praise of their good qualities is far more likely to strengthen them on the best side of their characters.

Envious thoughts are best corrected by laboring for self-improvement.

The Unreliability of the United States Pharmacopœia and National Formulary Imitations.

One of the leading druggists of Wilmington, Delaware, writing to one of the drug journals, says: "We all know that small quantities of U. S. P. and N. F. preparations will not be made by twenty thousand druggists without differing in taste, color or *some other way;* and, further, there will be the temptation to make too much, and therefore to keep it too long, and then dispense it over the counter. *That the physician can not be sure he is getting exactly the same preparation whenever he writes for a U. S. P. or N. F. product will be, at least, a good excuse for not prescribing them.*"

Now, the case against the movement which the pharmaceutical associations have started, and in which the A. M. A. officials, in their desire to win the druggists over to them, and get their aid in the furtherance of their legislative schemes, have joined, could not be more strongly stated. What the doctor wants above everything else in treating a patient is to feel certain that *he gets exactly the medicine that is prescribed*, but he can never have this assurance when his prescriptions are sent to first one druggist and then another, and *for the reasons so plainly set forth by the Delaware pharmacist.*

Now, a great many of the U. S. P. preparations, and nearly all of those in the National Formulary, are mere imitations of proprietaries which have been tried for years and found reliable. They can not possibly be *exact* reproductions, and are at best *mere approximations*, made up by guesswork. Then, what is the common sense thing to do when a doctor wants to prescribe for a patient? It seems to us he should prescribe the original proprietary, which he knows must be uniform, and which has behind it the reputation of the manufacturer. He can feel in this case that he is getting a remedy made up of the best of drugs, and upon which he can rely with as much certainty as is possible as regards a medicine.

A Mechanical Remedy.

In some persons, the gall-bladder does not empty itself readily, through some disturbance of the mechanism of expulsion. In these cases, intermittent pressure over the region of the gall-bladder, which is located at the edge of ribs and a little above on the right side, will start a downward movement of the bile towards the bowel.

The gall-bladder is thus evacuated, and the liver once more provided with a receptacle in which to store its secretion, thus relieving its obstructed channels of a substance foreign to them, and supplying the bowel with a necessary peristaltic persuader and a normal element of its digestive juices.

Bile which remains too long in the gall-bladder thickens, and gall-stones are liable to form. The liver substance becomes irritable and inflamed when constantly soaked in bile.

To mechanically express the bile, employ the ball of the thumb or hand, pressing downward from the edge of the ribs. Begin at the hip-bone, and extend around as far as the navel. Then make a return movement.

Kneading the liver for five or ten minutes each night and morning is a valuable mechanical remedy in torpid liver and biliousness of long duration. It paves the way for the successful action of indicated drugs. Sometimes it is sufficient in itself to relieve such symptoms as want of appetite, foul tongue, costiveness, etc.

Persistence, careful dieting, avoidance of colds, exposure in bad weather, etc., are necessary to secure the best results.

Colles' Law and Its Exceptions.

BY GEORGE OGILVIE, B. SC., M. B. (EDIN.), M. R. C. P. (LOND.),

Chevalier de la Legion d'Honneur;.
Senior Physician to the French Hospital, London;
Senior Physician to the Hospital for Epilepsy and Paralysis, London.
London, England.

No. 1.

The generally accepted doctrine, that the mother of a child that suffers from inherited syphilis can not contract syphilis from her own offspring is known as Colles' law by the whole medical world. It was first called "Colles' Law" by Diday in the year 1854, and not by Hutchinson, as erroneously stated by Dr. McDonnell, editor of Colles' works.

Having had occasion to consult the literature of this subject, I have been surprised to find that by some authors the paternity of this doctrine has been disallowed to Colles, and attributed to Baumès and that this view has been upheld in such well-known and widely read textbooks as those of Fournier and Kaposi. Fournier, with rhetorical effusion, exclaims, "Rendons à César ce qui appartient à César," and replaces the name of Colles by that of Baumès. Kaposi, however, contents himself by saying that it is more correct to call it after Baumès; and Bergh expresses himself in a similar manner.

Considering that Colles' book was published three years before that of Baumès, I was interested to find out on what grounds the continental writers tried to sever his name from this law, the formulating of which must always be regarded as a high testimony to his powers as a clinical observer.

The perusal of what has been written on this matter has convinced me that the alteration introduced by the writers above mentioned is in no way justified, some of Colles' statements having been either misconstrued or misrepresented. I believe that the following presentation of the arguments adduced by these writers, and the criticism of those arguments in the light of Colles' original text, will prove their fallacy. I wish it, however, to be understood, that in the following remarks the validity of Colles' law is not discussed, but only the history of its origin.

I will give first of all a short sketch of Colles' own remarks on this subject. They are to be found under the heading, "The appearance and nature of those diseases which are communicated by the infant to the nurse." Their object is not to discuss the question of the mother's state of health before and after the birth of a syphilitic child, but to prove the infectious nature of the secondary symptoms of the child, and at the same time to show the identity between the disease transmitted by the child to the nurse, and that acquired by the parents and trans-

mitted to the child. On these two points, both at the time when Colles wrote, and afterwards the teaching of John Hunter, was dominant. Colles' object was to disprove the correctness of Hunter's teaching, and to prove the identity of the acquired and congenital forms of syphilis. He therefore begins by giving a description of the nurse's disease, which commences at the nipple, and is followed by constitutional symptoms. He then remarks that he has never seen the nipple inoculated when the mother was the nurse of the child. He further relates a case which appeared to form an exception to this curious fact, but which, on closer inquiry, proved to be a case of syphilis acquired by the child after birth, and given to the mother. In commenting on this case he says:

(a) As yet I have not seen any instance in which an infant infected by the mother communicated a venereal ulcer of the nipple to her.

He then speaks about the treatment of nurse and child, or nurse alone, by mercury. He shows how the disease which has been traced from the parents to the child, and from the infant to the nurse, might be communicated by the nurse to her husband, and might also, through secondary symptoms, spread to the dry nurse or any other person handling the child. In proof of this he gives three cases of which the first only, at present, is of interest. A servant girl is infected by a child, both parents of which had syphilis two years before its birth. Here Colles remarks:

(b) And let it be observed that the mother had not in any way suffered from the disease of the child; she had not received any infection from her own child, yet the disease was capable of infecting the servant girl. These statements will be referred to in the following remarks as (a) and (b).

The four cases referred to are the only cases given by Colles, *i. e.*, the first to show how mistakes might occur between acquired syphilis in infancy, and congenital syphilis, the last three to show how congenital syphilis might be the source of the acquired form. Not one of these cases is intended as a corroboration of Colles' law. In fact, no attempt has been made on the part of Colles to demonstrate this law by enumerating any personal observations. Having accomplished his task of describing the disease communicated by the infant to the nurse, and of establishing its specific nature, he winds up by once more mentioning the fact of the immunity of the mother. This is referred to altogether three times. The three references are as follows:

1. The following fact appears to me deserving of notice: I have never seen or heard of a single instance in which a syphilitic infant (although its mouth be ulcerated) suckled by its own mother had produced ulcerations of her breasts; whereas very few instances have occurred where a syphilitic infant had not infected a strange hired wet nurse, and who had been previously in good health.

2. It is a curious fact that I have never witnessed, nor ever heard of an instance in which a child deriving the infection of syphilis from its parents has caused an ulceration in the breast of its mother.

3. One fact well deserving our attention is this, that a child born of a mother who is without any obvious venereal symptoms, and which without being exposed to any infection subsequent to its birth, shows this disease when a few weeks old, this child will infect the most healthy nurse, whether she suckle it or merely handle and dress it; and yet this child is never known to infect its own mother, even though she suckle it while it has venereal ulcers of the lips and tongue.

Of these three different ways of stating Colles' law, No. 1 is the most definite. It must be borne in mind that Colles was well aware that the mother of a syphilitic child need not present, either before or after the birth of the child, a single symptom of syphilis, and that in undoubted cases of congenital syphilis the most careful examination might reveal nothing except the history of previous disease in the father. Particular stress must be laid on this fact, as it has not been pointed out by any of the writers on the subject. Therefore, the rule as formulated in No. 1 is the fullest and most precise expression of the fact known as Colles' law.

Almost the same may be said of No. 2. The difficulty arising from the interpretation of the words "its parents" is not real. Certainly "its parents" might mean both parents or either of them; but that the last interpretation is undoubtedly the correct one follows from the fact that, according to Colles' the child may derive syphilis from one or both parents, and that the mother might to all appearance escape altogether. The interpretation of any text must be given in conformity with the views of the writer on the entire subject; and although I am aware of the difficulty which the words "its parents" might present to a purely philological mind, the meaning is clear to any medical man who has read the whole of Colles' book.

In the same spirit one has to read No. 3. Here the words "Who is without any venereal symptoms" are open to attack, as the possibility of past syphilitic symptoms is not excluded. It must be admitted that the meaning here is less clear than might be desired, but in the face of the former statements, one has without doubt only to deal with a certain laxity of expression.

I have before quoted, under (a) a remark of Colles', which also suffers from indefiniteness of expression, even to a greater degree than No. 3. That a child "infected by the mother" does not communicate the disease to her nipple is a truth which forms only part of Colles' law, and can not be considered as an adequate expression of its whole meaning. The phrase merely states the fact that as the mother is actually suffering from syphilitis, she can not, of course, be reinfected. In the same way, the remark (b) only says that a mother who had previously contracted syphilis, and transmitted the disease to her offspring, can not be reinfected by the latter. Neither of these remarks was made in reference to cases adduced for the purpose of proving Colles' law, and, although they illustrate part of it, they were not intended to express its full meaning. They merely show that the mother who has had at any time symptoms of syphilis does not contract a chancre of the nipple from her syphilitic child. The observation first made by Colles is, that "whilst wet nurses not infrequently contract chancre in the nipple from nursing syphilitic infants, such accidents never happen to the infant's mother." That mothers might give birth to syphilitic infants without ever exhibiting in themselves any symptoms of syphilis *was known to Colles.*

It is well to bear in mind that Colles' observations were not made to fit or support any particular theory. His work was written, to use his own words about another worker on the same subject, "by a man who had no particular theory or doctrine to support, who seems to have written for the mere purpose of stating facts, and recording an account of the propagation of this afflicting disease." It may be doubtful whether Colles fully realized the theoretical bearing of his law. Regarding those cases in which the mother remains free from symptoms, he says that they are "so strange and so difficult to explain that nothing short of actual observation could induce us to allow the fact." He does not attempt their explanation; but whatever their explanation may be, whatever conclusions may have to be drawn from them, *he was aware of their existence.* He simply stated them as facts of actual observation, just as he stated it as a fact of mere clinical experience that a syphilitic child nursed by its mother does not infect her. No better and more definite expression of this rule could be wished for than Colles' own words quoted under No. 1, by which he introduces the subject under discussion. It will be found that reference to this most precise expression of his law is either omitted by his detractors, or that it has been misconstrued in a manner neither warranted by his words, nor by his teaching in general.

In order to discuss the different interpretations which have been given to Colles' words, it seems best to record them in the same chronological order as they appeared in the controversy evoked by a paper by Behrend. He was the first to question whether Colles really meant what is now understood as the law bearing his name. His whole argument is contained in the following sentence: "Moreover, up to the most recent date all the authors who reproduce the above rule formulated by Colles have not noticed

that its framer in corroboration of it communicates the history of a case, and mentions expressly that two years before he had attended the father as well as the mother of the child for secondary syphilitic ulcerations, and that he does not speak about mothers who never showed a symptom of manifest syphilis, but only of those who had no visible venereal symptoms, and who consequently had latent syphilis."

Behrend therefore concedes to Colles only the authorship of that part of the law which says that a mother who has had syphilis is not liable to be infected by suckling her child, while he attributes to Baumès the other part which says that the mother who has apparently escaped syphilis is not infected by the child to which syphilis has been transmitted from the father through her. To have united these two parts into one law, which says that a child suffering from hereditary syphilis does not infect its mother by suckling, is, according to Behrend, due to Diday, and he therefore considers the latter as the real author of what is commonly called Colles' law.

In reference to the case alluded to by Behrend, it was not given by Colles in corroboration of his law, but to show how congenital syphilis in the child might be the source of acquired syphilis in the servant. He only mentioned, by the way, the fact that the mother was not infected, while the servant was. The second part of Behrend's sentence refers to No. 3. I have already mentioned that the words "without any obvious venereal symptoms" do not *exclude* the possibility of venereal symptoms in the past, but I fail to see how they can *prove* the existence of former symptoms. If this kind of argument is to hold good, a general treatment of the human race by mercury would be indicated. Behrend quotes neither No. 1 nor No. 2, and therefore overlooks the fact that what he ascribes to Diday has already been said in identical words by Colles.

Behrend's statements were accepted by H. and M. Zeissl, and incorporated in their well-known text-book. To this Diday and Doyon replied by quoting No. 2, and remarking that they understood the words "without any obvious venereal symptoms" as meaning that the mothers had not had at any time any symptoms, while Behrend understood them to mean that there were no symptoms at the time of observation. Although the interpretation of Behrend is correct from a strictly grammatical point of view, I have pointed out before that in the light of No. 1 and No. 2, the interpretation of Diday alone is admissible, it being true to the sense if not to the letter. Diday adds that Colles had been understood in the same sense by Ricord and Fournier.

In 1883, Behrend's answer appeared under the title, "Is the so-called Colles' law a law or not?" He quotes in full the case to which he referred in his first communication, repeating his erroneous statement that Colles had given the case to prove his law; and he also repeats, without mentioning No. 1, that the equivocal words in No. 3 point to present and not to past symptoms. His attention being drawn by Diday to No. 2, he contends that the words "its parents" *must* be understood by every one as both parents, and that was meant by Colles. As shown above, the words *might* be understood as meaning either both parents or one of them; but they must be understood in the latter sense for the two reasons already given, viz., that Colles states himself that the child may derive the disease from one or both parents, and that he was aware of the cases in which the mother apparently escapes. Behrend winds up by repeating that, in adding the "additional" thesis of Baumès to the "original" thesis of Colles, Diday formulated what is wrongly called Colles' law.

Behrend's reply was followed directly by an article from Diday and Doyon, entitled "The Letter and the Spirit of Colles' Law." The writers insist upon the fact that not one of Colles' cases is intended as a proof of his law; that the meaning of the words "its parents" in No. 2, is not to be interpreted in the sense in which Behrend understands them; and that if they are properly understood as signifying "either of them," Colles' statement quoted under No. 2 is identical with the law formulated by Diday.

Here the controversy between Behrend and Diday ends. It thus appears that

Colles' most precise expression of his law No. 1 was never adduced on either side; that No. 2, misinterpreted by Behrend, was considered identical by Diday with his own enunciation of the same law; and also that the purpose for which Colles published his cases being misunderstood by Behrend, their importance and bearing were not rightly estimated by him.

A remarkable feature of this discussion is, that it was Diday to whom Behrend gives credit for having rightly understood and best formulated what is meant by Colles' law, and to whom he consequently grants its authorship—who, finding his views unmistakably expressed by Colles, first introduced the expression "Colles' law." He twice gracefully declines the honor which has been thrust upon him, thus vindicating Colles' rights, and protecting himself against "his friends." One might have expected that Diday's definite declaration would have put an end to this controversy, settling it in Colles' favor.

This expectation was not realized, however, for a paper was published in 1889 by Morel-Lavallée, who, under the advice of Fournier, once more undertook to examine into the merits of the contradictory statements previously made. Not a single argument that had not been previously adduced by Behrend is brought forward by Morel-Lavallée to strengthen his assertions, nor has one of the old arguments been shown in a different or more convincing light. He does not dispute, as Behrend did, that the words "its parents" might be interpreted as "either parent," but this interpretation he considers to be "slightly forced."

He again lays the whole stress upon the two quotations (a) and (b), which to him contain the "striking and blinding proofs" that Colles never meant to speak of cases where the father was syphilitic and the mother healthy. Of these cases however, Colles did speak; he was well acquainted with their occurrence, and his teaching was that the hereditary syphilis of the child involves no danger to the nursing mother. Morel-Lavallée again adduces the same two cases of Colles, of which one was given to prove the infectiousness of the hereditary disease, and the other to show how it might be mimicked by the acquired form. Both these cases exemplify that part of Colles' law which is explained by the unity of the two different forms of syphilis. Therefore the remarks attached to them only refer to these individual cases, and can not be quoted as the full expression of Colles' law. Under No. 1, No. 2 and No. 3. I have given above the three different ways in which this law is presented in its entirety in Colles' book, whilst (a) and (b) only represent its more restricted truth. Morel-Lavallée founds his arguments on these casual remarks, and by unjustifiable generalization he tries to throw doubt on the most definite statements made by Colles; but while he does not strengthen Behrend's case by adducing anything useful in argument or fact, he tries to weaken Colles' case by such extraordinary tactics of interpretation that I can not allow them to pass unexamined. The words "the most healthy nurse" furnish the basis for the following remarks, viz., that what Colles considered as the surprising feature was the fact of the healthy nurse being infected, and not the fact of the mother escaping infection, and that Colles would have been less surprised to see the nurse contract a chancre of the nipple if she had been infected before; in fact, he would have expected the healthy nurse to escape, and the syphilitic mother to be reinfected. According to Morel-Lavallée, Colles was under the idea that the syphilitic infection diminishes the resistance of the constitution, and therefore increases the predisposition to reinfection; that, in fact a healthy person, and still more a "most healthy" person, was less liable to be infected than a person already affected with the disease. There is not a single word, however, in the whole of Colles' book to bear out what are given here as his views, nor does Morel-Lavallée, while he faces the "danger of further diminishing Colles' merit," even attempt to adduce a reason for his supposition.

The meaning of the words "the most healthy nurse" appears most obvious, *i. e.*, a nurse who never had any trace of specific disease, about whom, therefore, no doubt could exist that the disease was contracted from the infant, and not from

any other source. Morel-Lavallée detects the same error in No. 1, where Colles says that "very few instances have occurred where a syphilitic infant had not infected a strange hired wet nurse, and who had previously been in good health." Morel-Lavallée exclaims, "This is always the same turn of thought; if the nurse had been tainted previously, Colles, it seems, would have been less surprised to see her (re-)infected, than to see her contaminated, having previously enjoyed good health." How else, or in what plainer words, could Colles have said what he wished to say, viz., that the nurse up to the time of infection by the child was healthy, and free from syphilitic infection, and therefore the origin of the infection could be established beyond doubt?

As the champion of Colles' priority Diday appeared again with a paper called "An Inquiry into Paternity: Colles? Baumès?" He rightly refers the reader to his former articles, and the arguments adduced therein against Behrend, of which not one has been invalidated by Morel-Lavallée, and he again points out that his own formulation of Colles' law, which has been generally recognized as a correct and complete one, is identical with that of Colles.

To this Morel-Lavallée replies in a letter in which he says that he withdraws from the discussion, although still conserving his opinion, because the whole question is one of translation and interpretation of an English text, a matter on which a man ignorant of the subject of syphilis could give an opinion if he knew English sufficiently well. I agree with Morel-Lavallée that a sufficient knowledge of English is all that is necessary to understand the meaning of Colles' words, and I trust that they will be understood in the future in the same sense which led Diday to affix Colles' name to the remarkable law first pointed out by the latter.

As regards Baumès, Morel-Lavallée adopts Behrend's view that what since 1854 has been understood under the name of Colles' law consists of two parts, viz., one part pronounced by Colles, the other by Baumès, and that these two parts were first united into one law by Diday. If it were true that Baumés had introduced a fact not observed by Colles, which has to be added to Colles' observations in order to establish Colles' law, why replace Colles' name by that of Baumès, and not by that of Diday? According to Behrend, and Morel-Lavallée, Diday first enunciated in an unmistakable and precise form what was wrongly called Colles' law, though called so by Diday himself. Behrend, therefore, consistently claims for Diday the authorship of Colles' law, restricting Baumès' merit to the "additional" thesis. Morel-Lavallée, on the other hand, in contradiction to his own statements, replaces the name of Baumès for that of Colles, although either of them, according to him, originated only part of the latter's law. To this inconsistency he might have been driven by the awkward position of otherwise having to give to the law a name the bearer of which declines its authorship.

It has further been argued in favor of Baumès that while Colles did not support his law by detailed facts, Baumès did so; but, in looking at the two observations which the latter relates (two mothers, one suckling five, the other two children without being infected), we find that in not one of the infants was the mouth affected, although they showed other signs of hereditary syphilis. Therefore, these cases do not fulfil the principal condition which every case of this kind has to meet, and which has been repeatedly insisted upon by Colles. As they do not even show the possibility of a local infection, they can not demonstrate the immunity of the mothers.

I may mention an interesting fact communicated by Diday. Two years before the publication of Colles' book, Baumès visited England, bent on studying the medical schools of our country. At this time the original idea of Colles, already professed by him, must have been known, and it is not impossible that Baumès might have learned Colles' law, either from his own lips or through those influenced by his teaching. Therefore, to call the law after Baumès is most obviously a misnomer, and in direct opposition to the facts granted by those who are responsible for it.

The law, if not called after Colles might have been called after Diday; but here the difficulty arose that Diday, know-

ing his indebtedness to Colles, disclaimed any share in the framing of the latter's law. Baumès is only the figurehead under which the unsuccessful attempt on Colles' rights was made.

[Written for the MEDICAL BRIEF.]

The Diagnosis and Treatment of Mitral Disease.

BY FREDERICK W. PRICE, M. B., C. M. (EDIN.), M. R. C. P. (LOND.),

Medical Registrar to Westminster Hospital and Assistant Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest, London, England.

The subject of mitral disease is important for many reasons. First of all, in regard to diagnosis, a systolic bruit audible over the apex of the heart is frequently erroneously interpreted as indicative of organic disease of the mitral valve, when it is due merely to anemia or dilatation of the left ventricle. On the other hand, mitral stenosis is a lesion which is often missed, as patients come complaining of cough and shortness of breath, or of hemoptysis, and the heart is either not examined, or, if examined, the characteristic murmur is not discovered, from the fact that it is heard over only a small area of the precordia. Secondly, the treatment of mitral disease is a matter of great concern; for, although it is true that we can not remedy a damaged valve, it is none the less true that we may by therapeutic measures extend the life of the patient for several years.

Diagnosis.—The three main channels of inquiry in regard to diagnosis are the history, the symptomatology, and physical signs.

In regard to history, the patient has almost always suffered from a previous attack of acute endocarditis, for whereas aortic disease is due to a primary sclerosis of the valve coming on insidiously during or after middle life, and associated with arterio-sclerosis, mitral disease rarely arises in this way. Practically the only class which does not conform to this rule is that in which the disease comes on between the ages of fifty and seventy, more commonly in women, and associated with chronic Bright's disease, and atheromatous vessels. The attack of acute endocarditis may be caused by rheumatism, chorea, or scarlet fever. It should be remembered that the rheumatic attack may not be a typical one; it may be very mild, or show itself in an aberrant form. Thus, a child may suffer merely from slight and fugitive pains in the joints, with no swelling or noticeable fever, or may complain of what are called "growing pains." Rheumatic nodules are sufficient evidence, and should always be searched for in childhood, as should erythema nodosum. Indeed, there is reason to believe that endocarditis may be the first manifestation of rheumatism. From this we learn that a child, or an adult for that matter, where there is a family history predisposing to rheumatism, should have the heart systematically examined, to make sure that there is no disease.

The diagnosis of an attack of acute endocarditis is of importance, for if it is possible to make a definite diagnosis of this condition, it is certain that the patient will sooner or later develop chronic valvular disease, though it may not be for many years. A large percentatge of cases in which a mitral systolic murmur is heard during the course of an acute febrile illness recover with a disappearance of the bruit, but this is because the murmur was due either to simple cardiac dilatation or anemia, associated with the febrile attack, and not due to acute endocarditis.

What are the distinguishing features, therefore, of an acute inflammation of the endocardium? In endocarditis, before establishment of a definite murmur, there is always a prolongation of the first sound. This preliminary prolongation is strongly in favor of inflammation. The early appearance of a murmur, that is, the occurrence of a murmur at an early stage of an attack of acute rheumatism, is in favor of endocarditis; for when it is due to dilatation of the left ventricle, or to anemia, it occurs only after the illness has gone on for some time. A soft, blowing quality of the murmur in contrast with a harsh bruit is of some help. A diagnosis of acute endocarditis may be made when there is a definite and considerable accentuation of the pulmonary

second sound, provided that there is not sufficient degree of congestion of the lungs to account for it.

If the murmur is purely hemic, it is often heard over the base of the heart as well as in the mitral area. When a mitral presystolic bruit is heard, there is not the least difficulty in making a diagnosis, but, as a rule, this murmur is not heard during an attack of acute endocarditis; it is heard only when a sufficient time has elapsed to allow of contraction taking place.

It should be remembered that in by no means a small proportion of cases the most careful search fails to obtain a history of any of the known causes of heart disease. These cases come on quite insidiously. A certain proportion of them are in anemic young women, who complain of shortness of breath, hemoptysis, or of the symptoms of bronchial catarrh.

For what symptoms does a patient with mitral disease seek advice? It may be mentioned that a certain number first come under medical care for some lesion of the nervous system. Hemiplegia, or aphasia, or both, coming on suddenly, and due to arterial embolism, is the commonest lesion, but hemichorea may occur instead. Mitral stenosis is the form of valvular disease which, apart from inflammation or ulceration of the valve, most commonly gives rise to arterial embolism. It is due to the detachment of fibrinous coagula from the left auricle or left auricular appendix; less frequently from the left ventricle. On *post-mortem* examination, embolism is most frequently found in the brain and kidneys—in about equal proportion—and next commonly in the spleen.

There is another class of patients who come complaining of anemia, progressive wasting, and other disorders of nutrition suggesting pulmonary tuberculosis, especially when there is hemoptysis and local consolidation of the lung. This local consolidation is by no means uncommon, and is due to infarctions of branches of the pulmonary artery.

The commonest symptoms are associated with the pulmonary circulation, so that breathlessness is one of the first symptoms. It may be only on exertion, but later on, when there is failure of compensation, it is apt to be constant, and ultimately may amount to orthopnea. Epistaxis is by no means an uncommon symptom. The patient is also liable to congestion of the lungs after exercise, and the capillaries may rupture, with resulting slight hemoptysis. *When a patient complains of spitting of blood, the heart should be examined, as mitral disease, especially mitral stenosis, is one of its commonest causes.*

From venous stasis, there is a tendency to pulmonary affections, such as bronchitis. When in congestion and edema of the lungs there is breathlessness and cough, the expectoration is often blood-stained. There is cyanosis of the face, varying in degree to a purple color. Pain is not a frequent symptom, and when present it is usually localized, and does not radiate to the shoulder and arm. The patient may suffer from headache and insomnia, due to the anemia of the brain. When the right side of the heart fails we get the symptoms of pronounced tricuspid incompetence. The liver is enlarged, tender, and may be pulsating. Generally speaking, edema is not nearly so marked a symptom in stenosis as in mitral incompetence. Ascites is often present, and rarely sets in before the dropsy of the feet and legs. It should be remembered that in mitral stenosis hydrothorax may occur without any dropsy elsewhere, and it should always be searched for. Recurrent endocarditis is a frequent complication, and pulmonary apoplexy is common.

Passing to the differential diagnosis between mitral incompetence, due to chronic valvular disease, from what is called a functional mitral murmur, the points to be taken into consideration are these: The fact that the patient has had a previous attack of acute rheumatism or chorea, the fact that he has suffered from shortness of breath on exertion or edema about the ankles. We can not rely much upon these, for in anemia there is always dyspnea on exertion, and there is frequently slight edema. But it is possible to make a definite and certain diagnosis of mitral incompetence, which is due to organic valvular disease. There are three main physical signs, namely, the position and character of the apex-beat, the area

of propagation of the systolic murmur, and the presence or absence of accentuation of the pulmonary second sound. In mitral incompetence, due to organic valvular disease, there is hypertrophy of the left ventricle. When hypertrophy is present, the apex-beat is not only pushed a little outwards, but it is also displaced a little downwards. There may be such a slight degree of valvular disease that there is no definite displacement of the apex-beat in either direction. But in those cases where it is not displaced there is almost always some alteration of its character. It becomes rather more forcible, whereas in functional conditions naturally it is less forcible than normal.

The area of propagation of the murmur is of significance. If it is propagated towards the angle of the scapula beyond the mid-axillary line we may be practically certain that it denotes organic disease. In practice I find this a safe and guiding rule. Regarding the accentuation of the pulmonary second sound, as long as there is no condition of the lungs to give rise to it, when the accentuation is definite and considerable, we may be sure that we are dealing with organic disease of the mitral valve.

A word of warning may be uttered in regard to the importance of being on the look-out for what are called cardio-pulmonary murmurs. A cardio-pulmonary murmur is a murmur which is due to some condition of the lung, the pleura, or of the mediastinum, and not to any condition of the heart. We should always exclude them in every case in which a murmur over the precordia is heard. They are apt to throw us off our guard when there is either pulmonary tuberculosis or a thickened and adherent pleura or fibrosis of the lung of the left side, or when there is a pleurisy with effusion of the right side, because in all these conditions the apex-beat may be displaced outwards. It is rarely displaced downwards.

How are cardio-pulmonary murmurs to be diagnosed? There are two distinguishing features. First, they always disappear when a patient takes a long breath, and holds the breath in; whereas they are increased in loudness during expiration. The other point is that they disappear when the patient lies down.

Passing to the diagnosis of mitral stenosis by physical examination, the pulse is of supreme importance. It is more frequent than is normal, but is often quite regular until compensation has considerably given way. It is irregular when there is associated regurgitation present. It becomes irregular first in force, and then in rhythm, and ultimately some of the beats fail to reach the wrist, due to the fact that the left ventricle is not receiving its proper quantity of blood. But the important point is that the pulse is *small*, and its tension is comparatively high unless there is accompanying incompetence.

The apex-beat is displaced outwards to the left, and not downwards, for there is no hypertrophy of the left ventricle, unless there is mitral incompetence as well. There is a thrill felt at the apex or internal to it, usually presystolic, or it may be diastolic in time. On palpating the precordia, there is a sensation communicated to the hand resembling that produced by the purring of a cat. This sign is almost pathognomonic, though in a few cases of aortic incompetence we get a similar thrill, and this disease should always be excluded. The thrill must be distinguished from a mere vibration of the chest wall, which is occasionally caused by the action of an energetic heart on rigid ribs; but there is an easy method of doing this, for by separating the fingers, and placing them in the intercostal spaces, the osseous vibrations are not felt. The thrill may be absent at some periods, and present at others. It may be absent when at rest, and developed after exertion, or when the arms are extended.

Usually the transverse diameter of the heart is increased, especially to the right. In the large majority of cases the murmur is present. It is heard at the apex or between it and the left border of the sternum. The locality of the murmur is very limited, and the area may not be larger than one inch in diameter. This fact should be particularly noted, because here is one of the most common causes why this lesion is so often missed. The murmur is usually presystolic in rhythm; that is to say, it occurs during the ventricular diastole, but at the end of that period, and it coincides with the auricular

systole, which immediately precedes that of the ventricle. A distinctive feature is that it runs up to and unites with the first sound, becoming louder as it proceeds, and being cut short at its loudest. The murmur is rarely blowing or musical, but is almost invariably rough. It may be harsh and vibratory; this harshness and vibratory quality are characteristic.

The first sound which terminates the murmur is also altered in a characteristic way. It becomes short, sharp, and clear, like a sudden snap. In some cases this is observed when there is no bruit. If such a condition be heard in the neighborhood of the apex, and we are suspicious of mitral stenosis, we should search for other signs. The second sound is reduplicated, and resembles a "postman's knock." This may be observed in the neighborhood of the apex, or at the base of the heart. Instead of finding a presystolic murmur, we may find an early diastolic or a mid-diastolic bruit.

If there is a thrill, a murmur, a short, sharp first sound, a reduplicated second sound, and the pulse has the characters already mentioned, we have no difficulty in making a diagnosis of mitral stenosis. I have already said that the murmur is often localized. It is true that the presystolic bruit is not absolutely pathognomonic, for it is heard in some cases of aortic incompetence, but the pulse, the position and character of the apex-beat, the "purring" character of the thrill, the character of the first and second sounds, all afford help in making a positive diagnosis.

Another condition which may be mistaken for mitral stenosis is where a rumbling presystolic sound is heard in children, after an attack of pericarditis. But the sound has not the vibratory character that is found in mitral stenosis, nor does it terminate abruptly in the first sound, nor is the first sound modified in the way described.

A more difficult class of case from the diagnostic point of view is the class in which the murmur is absent at the time of medical examination, though it may have been present before. In some of these cases a thrill is present. Should it be absent, we are justified in inferring that there is mitral stenosis from the character of the pulse, of the first sound at the apex, and the accentuation of the pulmonary second sound. Mitral stenosis is also sometimes missed in cases where there is associated incompetence. The presystolic murmur, instead of ending in the first sound, ends in a systolic murmur, and is often taken for a long regurgitant bruit alone. There is, however, a distinct difference in character between the former and latter parts of this continuous murmur. We can make out the rhythm by placing the finger upon the apex-beat or carotids. A mere reduplication of the first sound at the apex is sometimes mistaken for mitral stenosis, but no careful observer would make this mistake.

In the second stage of the disease, the second sound at the apex disappears, the short, sharp, first sound becomes louder, and the murmur is more frequently early or late diastolic than presystolic. Here the presystolic murmur may be mistaken for one systolic in time, and the altered first sound for the second sound. This should cause no difficulty, for we can time the murmur in the manner already indicated. Furthermore, the systolic bruit is blowing or musical, and begins with an accent, whereas the presystolic is rough and vibratory, and ends with an accent.

In the third stage of the disease, the murmur usually disappears, so that all that is heard at the apex is the short, sharp, first sound. This stage may also be mistaken for dilatation of the left ventricle, but in dilatation, a second sound is heard, while it is absent in the third stage of mitral stenosis.

Treatment.—We must consider this part of the subject fully, because its importance is not sufficiently realized.

First, in a child, if there is the slightest suspicion of rheumatism—for example, if the child has fugitive pains in the limbs or joints, or slight fever, or rheumatic nodules—we should repeatedly and carefully examine the heart, because joint affections are usually mild in children, whereas the endocardium is frequently involved. Even if the heart is attacked the symptoms of endocarditis are often very insidious. If there is the least suspicion of endocarditis, the only safe plan

to follow is to keep the patient in bed until all doubt is over. When dealing with a definite attack of endocarditis, we should keep the child in bed or in the room for some weeks, or even two or three months after the attack is over, in order to afford the heart the best chance of undergoing compensatory hypertrophy. It may be pointed out that a febrile attack occurring during childhood or adolescence in the subject of mitral disease should be treated as though its cause were rheumatism by the administration of salicine or salicylates.

It is difficult to settle how far a patient with mitral disease should be allowed to live his ordinary life. Hard and fast rules are not applicable, because the constitutions of different patients differ enormously. But there is a great cardinal principle which is of service. It is this: *Any exertion which the patient indulges in should not produce any undue breathlessness, distress, or fatigue, especially the last named.* Sudden and violent exertion should be avoided. When exercise is taken, it should be entered upon gradually. For example, in going up a hill, the patient should commence at a slower rate than when walking on the level. Systematic exercises are good, provided care be taken, for they are a help to the venous circulation; and, by expanding the chest, they tend to aspirate the heart, and increase the outflow of blood from the auricle to the ventricle.

In this connection, Schott's or Ortel's forms of treatment are useful during the stage when compensation is maintained, but not later. A patient with valvular disease should lead a quiet and carefully regulated life. A gravelly or sandy soil, where the rainfall is below and the sunshine is above the normal, is best. A winter in Egypt is beneficial. It is better for the patient to be a teetotaler, and avoid tobacco. The diet should be liberal, plain, and wholesome. Excesses should be avoided, especially of highly nitrogenous food, because it increases the resistance in the peripheral circulation. The three meals of the day should be fairly equal. A large meal causes too great a variation in the vascular system, and the heart does not readily adjust itself. The amount of fluid should be restricted, and the meals should be as dry as the patient will take them. We can not exaggerate the importance of paying strict attention to the condition of the bowels. Fecal matter in the large intestine gives rise to flatulent distention, and this, by direct pressure, embarrasses the heart, and is one of the commonest causes of palpitation.

Besides this, the large evacuation which is necessary in these cases causes a great alteration in the blood-pressure. In mitral stenosis, any existing anemia should be vigorously treated, because the systemic circulation is not well supplied with blood, so that what it gets should be of the richest quality; and also the nutrition of the heart is of prime importance. In mitral diseases, bronchitis and other affections of the lungs should, as far as is possible, be prevented at all costs, for an attack of bronchial catarrh is often just sufficient to throw the heart off its balance. It is also of importance to guard against rheumatism, which may cause another attack of endocarditis.

The patient should wear flannel or woolen underclothing, summer and winter, and avoid damp feet. Should there be the slightest manifestation of rheumatism, it should be carefully treated.

When compensation is evidently failing, and there are such symptoms as breathlessness, hemoptysis, or pain in the precordia, rest in the recumbent posture for some weeks is absolutely essential. Rest is by far the most valuable therapeutic measure which we have at our disposal in the treatment of valvular disease. If the patient is so ill that he is unable to lie down on account of the dyspnea, the body should be supported by pillows or a bed-rest, so as to relieve the strain from the muscles. Freedom from mental work and anxiety is also important, because the brain is a very vascular organ. Stimulants, if carefully given, may be of value. It is good to begin with a small quantity of wine with food. Ultimately stimulants in larger quantities are required, and good brandy is the best form. We should commence with two or three ounces per day, gradually increasing the quantity as required, but it is never advisable to go beyond ten ounces a day, and the amount should

be gradually reduced as the patient improves.

In mitral disease, the great tendency is the production of venous stasis. Therefore, the clear indication is to deplete the circulation, and thus relieve the work of the heart by diminishing the volume of blood. There are several channels by which we can do this. Perhaps the most satisfactory is to remove the portal congestion by free purgation, and thus relieve the over-distended right heart. A troublesome watery diarrhea is no contraindication to this, because it is frequently due to a passive congestion of the intestinal mucous membrane. Sulphate of soda and phosphate of soda, in equal proportions, in two or three teaspoonful doses, dissolved in water, and given before breakfast, is very good, but personally I prefer a purgative in which some mercurial preparation forms a part, such as calomel and colocynth pill, followed by epsom salts in the morning. It would be difficult to over-estimate the value of purging in mitral disease.

It is also advisable not to give digitalis or strophanthus until after free purgation. It is then—that is, after the volume of blood in the right heart has become diminished—that the organ has the chance of being helped to drive its blood through the lungs.

Six or eight leeches applied over the liver, and followed by hot fomentations, help to reduce the volume of blood in the right heart, and this affords great relief to the pain. Should the symptoms be more urgent, venesection may be advisable. Its indications are a small, weak, and irregular pulse, many of the beats being scarcely perceptible, whereas the right heart is felt to be powerfully pulsating in the epigastrium.

Another way to reduce the volume of blood is to act on the kidneys. The salts of potash, squills, scoparium, and digitalis, especially in the forms of infusion, are useful, and it is a good plan to try a combination of several. It is best to give mercury before commencing any of these drugs, as it starts diuresis.

Turning to cardiac tonics, iron, arsenic, and strychnine are extremely useful, and may be all that are required in the early stages. Later on we have to consider whether it is advisable to give such drugs as digitalis. They are not attended with such good results in mitral stenosis as they are in regurgitation, because in stenosis there is a permanent obstruction at the valve, and on account of this many physicians do not believe in their administration at all. The rules I would recommend in this connection are:

(1) Do not give them until there are symptoms of failure of the right ventricle.

(2) Do not commence until after free purgation for a few days, and, if necessary, leeching or venesection.

(3) On no account give them for a prolonged period. They should be stopped when they cause nausea and vomiting or headache, when the pulse becomes infrequent, or when the urine diminishes in amount, and for this reason the quantity of urine passed should be measured daily.

It is scarcely necessary to say that when compensation becomes established they should be stopped.

Digitalis is certainly the best drug to give in regurgitation. It may be given in the form of tincture, the powder, or the infusion; the last is best when dropsy is present. In cases where it seems inert when given by the mouth, there may be rapid improvement following the hypodermic injection of digitaline discs. They contain one one-hundredth grain each, and two of them at the most should be given. In many cases, however, digitalis causes the heart's action to become irregular, or increases an already existing irregularity, and it is also contraindicated when there is either preceding nausea or vomiting, or when these symptoms are caused by its administration. In these cases convalleria is better, and fortunately it is a diuretic. It should be given as the fluid extract in five to ten minim doses, or as the tincture in ten to twenty-minim doses.

Strophanthus and citrate of caffeine are good substitutes. Carbonate of ammonia and ether may be added to the remedies mentioned.

Treatment of Special Symptoms.—Some of these are very distressing, and should be treated in the following way:

Sleeplessness may be due to edema of the lungs, the patient waking up with

"night starts" just as he is falling off to sleep. Such a cause should be treated. Otherwise chloral amide should be tried. Paraldehyde in one to two-drachm doses is an extremely valuable drug in many cases. I have found a drachm of tincture of henbane in a little hot brandy and water often succeed.

Where all these methods fail, opium or morphia should be given. The hypodermic method is much more efficacious than when given by the mouth.

Vomiting is a serious symptom. It may be due to the digitalis. In this case, digitalini granules may be tried. If the symptom still continues, strophanthus should be substituted, otherwise such drugs should be stopped altogether. Milk is the best food, but in some it is not tolerated. In the gastric crises accompanying the failing heart, peptonized milk or milk gruel may be swallowed in sipping fashion, the patient never being allowed to take a distinct meal or a particle of solid food (Sir Wm. Roberts).

Peptonized enemas may be necessary. Iced champagne is good. If the vomiting is only slight, a brisk purge to relieve the portal congestion, and the administration of hydrocyanic acid and bismuth may suffice. A belladonna plaster may be tried for pain in the precordia and palpitation. Any possible flatulence of the stomach and intestines should be immediately treated. If the blood-tension is high, iodide of potassium, or nitro-glycerine is called for. If the symptoms still continue, morphia may be necessary.

Cough is best treated by digitalis, and carbonate of ammonia, and dyspnea by diffusible stimulants, but if there are evidences of edema of the lungs, dry cupping is by far the best treatment. It is best done when the patient wants to get to sleep, and it can be repeated. Hydrothorax should be examined for, and when present, the chest should be tapped.

Dropsy is best treated by acting on the bowels and kidneys, as already indicated. Digitalis is much better than strophanthus. Puncture or Southey's tubes are better than scarification; both should be done only under antiseptic precautions. In early dropsy, a flannel bandage wrapped round the limbs is very useful. Ascites should be treated by tapping or by Southey's tube. When ascites and general anarsaca are both present, the one which is the more predominant should be treated first.

[Written for the MEDICAL BRIEF.]

Cirrhosis of the Liver.

BY GORDON MUNRO, M. A., M. D.,
Glasgow, Scotland.

There are two main causes of cirrhosis of the liver, (1) alcoholism, and (2) syphilis. These two predisposing causes are often combined. This is not surprising, for the man who indulges too freely in drink is more likely than his temperate brother to place himself under conditions in which syphilis is likely to be acquired. It is said that interstitial hepatitis may arise from any infective toxin, and from many other substances taken as food besides alcohol. It is said, too, that the abuse of pepper, mustard and spices in hot climates is sometimes responsible for this condition, and in support of this theory it has been pointed out that the addition of pepper and capsicum to the food of dogs and rabbits will, after a certain time, produce a distinct increase in hepatic connective tissue. This may be true, but it seems to me that the average patient would have to take a good deal of mustard to account for his cirrhosis. Some cases of cirrhosis are undoubtedly malarial in origin, but practically the one and only cause of the disease is chronic alcoholism, with or without superadded syphilis.

Chronic alcoholism is the accompaniment of civilization. The more intellectual the race, the more frequently is alcohol resorted to in excess. In moderate quantities, even in health, it may prove beneficial, but over-indulgence in the habit is attended with the most disastrous results, even when never carried to the extent of intoxication. Chronic alcoholism is to a great extent a trade or occupation disease. Opportunity and temptation are the main factors in its production. This is readily illustrated: the vast majority of cases are met with, at all events in this country, in publicans, butlers, waiters, and commercial travelers. It is also common in "city men," many of

whom say they would do no business if they were not prepared to indulge in a "friendly glass" with a prospective client. Authors, press-men, and reporters, who have often to work at high pressure, urge that they could not perform their arduous duties unless artificially stimulated. In a large number of cases this is unfortunately true; they have become the victims of a habit or vice which it is impossible for them to shake off. The man who leads an active life is able to take more alcohol with impunity than the individual who spends the greater part of the day writing or in some similar sedentary pursuit.

Some people resort to alcohol because they are constitutionally weak, others because they are the victims of chronic neuralgia, or some other painful affection. Heredity is not without its influence, and the offspring of neurotic parents not infrequently fall a victim to the disease. Some of the worst cases are met with in married women, especially those who are childless. Their lives are monotonous; they possibly may have few friends or acquaintances. The husband leaves for his office early in the morning, and does not return until a late train for dinner. The wife makes a heavy mid-day meal, washed down with a pint of Burgundy, or a couple of glasses of whisky and soda. There is no one likely to call, she has no inducement to go out, and spends the greater part of the afternoon in a condition of somnolence. She has no real liking for drink, but resorts to it simply to kill time. As years go on she acquires the alcohol habit, which is just as deadly and pernicious as the custom of taking morphine or chloral.

Alcohol is taken in many forms, as whisky, or brandy, wines of various kinds, beer, cider, and liqueurs. There are variations in this respect, and individuals probably from accidental circumstances exhibit curious proclivities. Doctors are not without a certain influence in these cases, and that influence may be good or it may be distinctly harmful. The old-fashioned custom of advising every female patient to support the constitution by plentiful libations of stout, port wine and Burgundy has much to answer for. Fortunately, more enlightened views on this subject now prevail, and greater caution is exercised, especially amongst the leading men in our profession.

The symptoms of chronic alcoholism, even in the early stage, are characteristic and are easily recognized. One of the chief features is uncertainty of purpose—the patient is unable to make up his mind to any particular course of action, is habitually uncertain, and is careless in keeping his business engagements. He is at his worst in the early morning, but probably once started proves himself an able and capable individual. Many people who habitually consume too much, build up large businesses, and in spite of their particular and peculiar indulgence are immensely respected. This may be said with certainty, that different individuals manage to do their best work under widely different circumstances. Total abstinence does not suit every one, and many without a certain amount of alcohol would do no work at all. The total abstainer thinks that he in his wisdom can legislate for the rest of the community, and fails to recognize the fact that what may be good for him does not of necessity suit every one.

The symptoms of the disease are so characteristic as to call for very little detailed description.

In the early stage there may be indications of congestion of the liver, such as fullness or pain in the hepatic region, with a tinge of jaundice. There is frequently gastritis, producing loss of appetite, furred tongue and vomiting, especially in the morning. An examination of the abdomen may reveal considerable enlargement of the liver, of which the patient is entirely ignorant. The next symptom is hematemesis, due to commencing obstruction in the portal circulation. The quantity vomited is often considerable, as much as one or two pints; and the vomiting is followed or accompanied by the passage of blood by the rectum. Piles are not often present at the same time.

The next result of the portal obstruction is the effusion of fluid from the distended veins into the peritoneal cavity, constituting ascites. The abdomen rapidly enlarges by the effusion of fluid, which may reach several pints, while the

abdomen at the umbilicus may measure from forty to forty-two inches. In many cases, when ascites has developed, the liver is still in a state of enlargement, and can be felt an inch or more below the ribs, whilst the surface is rough, granular or nodular, and the edge is rounded.

If the organ has already contracted, it may be impossible to feel it. The spleen is often enlarged, and may be felt or percussed on. The surface of the abdomen is covered with large veins, running between the iliac and thoracic trunks. The bases of the lungs are compressed, and the heart is displaced upwards. The urine is scanty, high-colored, with an abundant deposit of red lithates, and not unfrequently a trace of albumin. This may be due to pressure on the renal veins, and is not an indication of co existing granular kidneys. The general health of the patient suffers much, and he is usually pale, thin and anemic.

Respecting the establishment of a collateral circulation, the following anastomoses between the portal and the general systems are the most important:

1. The coronary veins of the stomach anastomose with the esophageal, phrenic and left renal veins.

2. The vasa brevia of the stomach anastomose with the left phrenic veins.

3. The gastro-epiploica of the stomach anastomose with the left renal veins.

4. The superior mesenteric veins anastomose with the left renal veins.

5. The hemorrhoidal veins anastomose with the pudic veins.

6. Veins in liver adhesions anastomose with phrenic veins and veins in the abdominal wall.

7. The veins in the falciform ligament anastomose with the phrenic veins, and veins in the abdominal wall.

This differs somewhat from the classification of Sappey, which is as follows:

1. Anastomoses between the coronary veins of the stomach and the esophageal plexus which discharges into the lower intercostal and azygos veins, and also communicates with the diaphragmatic vessels.

2. Veins passing in the coronary and suspensory ligaments of the liver, and in the adhesions formed between the liver and the diaphragm.

3. The dilation of a small vein in the round ligament affording free communication between the portal vein and the epigastric vessels.

4. Veins forming the system of Retzius, which, originating in the intestinal canal and anastomosing with the radicles of the portal vein, discharge into the inferior vena cava and its branches.

5. Communications between the superior and inferior hemorrhoidal plexuses.

Cirrhosis of the liver is undoubtedly a very terrible disease, and the majority of its victims die within two years, but on the other hand it is rare compared with the enormous number of people who are chronically alcoholic. Even at its worst it is amenable to treatment. An out-door life, preferably in a sanatorium, plenty of fresh air and a fair amount of good food will do much to ward off its evil effects. Even when there is fluid in the abdominal cavity tapping and other operative procedures will go far to arrest the progress of the disease.

Incidentally it may be mentioned that the syphilitic cases usually do well on "mixed treatment," by which I mean the administration of the iodides in substantial doses, with simultaneously the inunction of blue ointment, or calomel ointment into the surface of the abdomen. This may be undertaken with advantage as a preliminary step, and when there is anemia it may be combined with a short sea voyage. Even if the patient is a poor sailor, it is by no means contraindicated for a few days sea-sickness is more efficacious than the administration of purgatives.

It is not in every case that the operation for the establishment of a collateral circulation is indicated, and the following rules laid down by Murrell may serve as a sufficient reminder.

A point of practical importance with reference to the success of the operation is the careful selection of the cases. We reject those in which there is a suspicion of carcinoma, whether of the liver itself or of the peritoneum, or of the adjacent organs. When there is a history of syphilis, the patient should be given full doses of iodide of potassium, with inunctions of calomel ointment, but should there be no improvement in the course of three

weeks, further postponement is inadvisable. The best results are obtained in the pre-ascitic stage, when the diagnosis rests on the alcoholic history with hematemesis and enlargement of the liver and spleen. Alcoholic subjects are bad subjects for operation, and it is not wise to wait until their tissues have undergone further degenerative changes. The earlier the operation, the better the chances of a successful issue. An elevation of a temperature of three or four degrees in the evening is not to be taken as a ground for postponement, nor is the presence of a trace of albumin in the urine. Many of these patients, as shown by the published records have an apex systolic murmur, and in the majority of cases it may be safely disregarded. The risks of ventral hernia have to be taken into consideration, but they may be minimized by the application of a firm binder as soon as the patient gets up, but this is a comparatively small matter when issues of such grave importance are involved.

The operation itself is attended with little risk, and in skilled hands, and with the observance of strict antiseptic precautions, is practically devoid of danger. Under favorable circumstances, the patient should be up and about again in three weeks. If the patient desires a permanent cure, he must consent to be for all practical purposes a total abstainer. This does not mean that he may not have a glass of beer with his meals, but that he must abjure whisky and all similar strong drinks. Moreover, he must take plenty of out-door exercise, and live as much as possible in the open air. The early cirrhotic may look forward to many years of useful life, provided always that he will consent to be no longer a chronic alcoholic. He will get well—but on terms.

Advance Knowledge.

On an average, medical knowledge is printed in medical journals from two to five years in advance of its appearance in medical text-books, hence the average working library composed of text-books alone is from two to five years behind the times.—MAYNARD A. AUSTIN, M. D., Anderson, Indiana.

[Written for the MEDICAL BRIEF.]

Some Observations on the Surgery of the Middle Ear.

BY GEORGE F. COTT, M. D.,
Professor of Otology in the Medical Department of the University of Buffalo.
Buffalo, N. Y.

In operating upon the ear we are taught the anatomy more or less thoroughly, but clinically we often find that our anatomy does not seem to agree. Many cases of disease of the ear are found in adults, some in old age, and a large number in children of all ages; many of the latter, however, are often overlooked. Before considering modern operations, let us look at the anatomy of the ear at different periods. The first year of infancy we find the antrum immediately above the tympanic ring; there is no mastoid present. Consequently, when necessary, the antrum may be penetrated through a thin shell of bone with a curette, and rather gentle pressure. The antrum recedes gradually with the development of the mastoid. At about ten years it will be found, instead of a large number of cells, but an enlarged antrum, or rather a large cell, forming one cavity with the antrum; access, therefore, is quite easy.

Mastoid cells begin to develop at puberty, differing from some of the other sinuses in this respect. The frontal sinus develops from the seventh to the twentieth year. The Antrum of Highmore is rudimentary at birth, and thence gradually forms. The ethmoid cells begin at the end of the fourth year. While the antrum of the middle ear is found in early fetal life. The middle ear and ossicles have relatively the same size in infancy and old age.

Now, bearing in mind the development of the structures of the temporal bone, you will notice how simple the operation the younger the patient is, in acute middle ear disease. Operations as performed at the present time give varying results. On the whole, many more patients get well than did formerly under the expectant treatment. It is very strange, but one class of men get good results in suppuration of the middle ear, with the dry treatment, while another class

get equally good results with the moist or washing-out treatment. On the whole, however, it is reasonable to deduct the following: Washing out in chronic middle ear disease is profitable when the discharge is kept up by the milder bacteria, such as pneumococci, which is the most virulent of the milder class.

Staphylococci, streptococci, etc., will seldom, if ever, disappear by the moist treatment. It is possible in a healthy and powerfully resistant patient to have the disease confined to the drum proper, eroded ossicles, and, perhaps, the walls of the tympanum. When, however, the antrum has become involved, and drainage is difficult to obtain, the number of cures are rare, indeed. Then, again, some cases get well under all kinds of treatment, or none whatever, even though the antrum be involved. The antrum, no doubt, is involved in many cases which get well by simply treating the middle ear. All things considered, the weight of evidence is very much in favor of the dry treatment. The cocci inhabiting the suppurating ear flourish in moisture, but become inert in dryness. Many cases of suppurating middle ears run uneventful courses for ten, twenty or thirty years, because Nature is very kind to us foolish humans, and barriers are set up which prevent disastrous infection of the meninges and brain, such as sclerosis, adhesions, granulations, etc., but a certain number of victims always pay the penalty. We have advocates of radical and advocates of conservative treatment in obstreperous cases, with the balance always in favor of the radical; for this reason operations properly performed can do no harm, while the "let-alone treatment" does occasionally cause death.

Now, radical treatment does not mean any special kind of operation, but means to eradicate thoroughly the diseased bone wherever found. It may mean partial removal of the posterior wall of the meatus to reach the antrum or complete exenteration or removal of cochlea or semi-circular canals, or laying bare the dura. It all depends upon the condition of the patient, and what is found as we go along. A number of times I found it necessary to open the skull and dura to follow up a sinus, when there were absolutely no symptoms indicating intracranial trouble. Conservative radicalism is a pretty good motto. That a radical operation is a serious undertaking for the unskilled, goes without saying, and no man should undertake it without first having operated several times upon the cadaver. After all, experience is the best teacher, and every man expecting to take up otology ought to see a large number of operations and results after having carefully studied the symptoms weeks before, if possible, otherwise he, too, will pay the penalty of rashness.

Now, let us follow up the average case: The patient has been treated for several months with different kinds of drugs or cleansing agents, gauze, drainage, etc., daily without result, and it is then decided to operate. What is our choice? Symptoms point to caries extending into the antrum. If the patient is an adult, and the discharge has lasted, say several years, we expect sclerosis of the mastoid, and would not think of removing that which does no harm, the mastoid process with its contents; we, therefore, after removing the soft parts make a fair-sized opening in the posterior wall of the external canal into the antrum, using a small gouge; if hearing is good, and the drum-head has a large opening, this method will prove sufficient. We may then cleanse the ear thoroughly through this opening without disturbing the mid dle ear at all, and our patient will not only get well but will have perfect hearing preserved. When, however, the patient has suffered a good deal of pain for some months, or weeks, or only days, ossicles totally or partially gone, with but remnants of the drumhead left, we may go farther and open the antrum externally, that is, chiseling away the posterior wall of the external canal, removing also the epitympanic outer wall as well, thereby converting the whole into one large cavity, especially if the hearing is much diminished or entirely gone. Feeling now with a probe, you may readily find some small opening in the bone, often over the middle ear, or posteriorly, or anywhere else, and following that up you may find the source of pain to be pachymeningitis, or perhaps epidural abscess, and your patient is saved.

It is possible, however, that a more severe lesion exists in the brain, the symptoms of which are more or less veiled by subacute or old inflammation in the middle ear. Thus brain abscess, or even ulceration of a large area, have been found *post-mortem* without even a symptom to indicate their existence. These however, are exceptional. A safe way is to remove all dead bone in a single case presenting no other symptoms than obstinate discharge. Constant or intermittent pain, or even more or less headache, demand careful search for channels of infection, for this generally means thickened dura or pus within the skull. Occasional headache, sleepiness, lassitude, vomiting, low temperature, slow pulse, etc., point to brain abscess, while rapid change in temperature may point to a thrombus, dizziness, staggering gait, or may mean cerebellar abscess. Of course, there are a number of symptoms modifying the above, or merging one with the other, which are found from time to time, but by careful observation and exclusion, one can at least know that something serious is going on within the skull, and that in all probability it is due to ear disease.

Of course, all cases operated upon do not recover completely; that is, a certain percentage of ears continue to discharge. Still, the graver danger of intracranial infection is, no doubt, done away with, but often a second operation of minor importance cures the patient.

To the beginner in operative otology, I would advise double caution when undertaking radical work or exenteration, for facial paralysis will occur often, no matter how careful he may be. My sixty-seventh case, in which I certainly was more careful than at the first, the patient developed unilateral paralysis the second day. This, however, always recovers when it comes a day or so after the operation, but it may be observed to some degree for from three to six months or more. If noticed immediately when the patient recovers from the chloroform, the nerve may have been severed, and anastomosis with the hypoglossal holds out the only possible means of improvement. It does happen that the shell holding the nerve becomes injured with curette or chisel, and may also become eroded by disease so that the exposed nerve can easily be injured and produce paralysis, for the slightest touch seems to be sufficient to paralyze the nerve completely for several months, so exceedingly sensitive is it.

In conclusion, let me add a word of caution: In all operations on the ear to be successful, "Be sure you are right, then go ahead."

A Case of Complete Prolapsus of the Uterus in a Young Woman.

BY GEO. C. BARTON, M. D.,

Dean of the Medical Department of Hamline University; Professor of Gynecology and Clinical Gynecology in the same.
Minneapolis, Minn.

This patient, a well nourished young woman of twenty-two years of age, was brought to me for treatment for a condition which is rather unique in a young woman who has never borne children. About seven years ago she had a severe fall from a ladder, and felt that she was pretty badly hurt. There was a sensation of something giving way in or near the pelvis. The next day she suffered with a dragging-down feeling, and as though some organ was slipping down into the pelvis, and this has continued until at present she has a complete prolapse of the uterus. The patient has been married but never pregnant. When she presented herself for treatment, her bowels had not been moved for several days. The rectum was full and the uterus seemed in normal position. The perineum and vulva were normal. I ordered a cathartic, to be followed by an enema. On examination the following day I found the neck of the womb protruding from the vulva and also a fold of the posterior wall of the vagina. This confirmed the diagnosis. She had some endometritis. The first step in treatment was dilatation and curettement. On passing a sound, the cavity of the uterus was found to be three inches long instead of two and one-half, the depth of a normal uterine cavity. This increased length was found to be due to an

elongated neck of the uterus. This elongated neck was amputated with a sharp scalpel, first dividing it bilaterally into two parts, amputating first the anterior lip, then the posterior, making a small flap on either side around the mucous lining of the cervix and a larger flap on the vaginal side. The vaginal mucous membrane was stitched to the mucous membrane of the cervix, going deep enough through the uterine tissue to occlude all dead space, and putting in three stitches on each side into the cervix, to form the new os, afterwards putting in the necessary stitches on either side of the os to close up the wound.

In order to retain the uterus in place, I did a ventral suspension through a small opening in the abdomen. Three sutures of chromicized catgut were used to fasten the uterus in place. The patient was kept in bed three weeks to allow the artificial support of the uterus to become firm. The result has been perfect.

1034 Andrus Building.

[Written for the MEDICAL BRIEF.]

Typhoid Fever.

BY A. N. ANDERSON, M. D.,

Professor of Physiology and Histology in the Nebraska College of Medicine.
Lincoln, Neb.

Of all the fevers a doctor is called upon to treat, typhoid most often engages his attention, and because of the frequency of its occurrence, its severity, and the possibility of some infirmity following, the disease demands our most careful consideration.

That the disease is caused by a specific germ, which enters the body, and causes an inflammation of the intestinal glands, is generally admitted. There are many sources from which this poison or germ can originate and produce infection, but defective drainage, and contaminated water supply the two conditions which are especially favorable to the growth and distribution of the bacilli. Filth, overcrowding and bad ventilation lower the resistance of the individual exposed. It is, therefore, necessary to see that we have a good water supply and perfect drainage and surroundings in general in a good sanitary condition.

Although bad water is a prominent cause of infection, we are prone to attach too much importance to water as a direct vehicle of infection. The germ can not multiply at water temperature. We will have one germ, perhaps, to gallons of water, and as it can not increase, the few germs there are taken care of by the HCl acid of the stomach. But this is not saying that we do not have infection through water, because upon standing it becomes a culture medium just as milk becomes a culture medium at room temperature, but when kept cold it is not. This explains to a certain extent why we have so much typhoid fever in the rural districts, and when an epidemic has started it is so hard to check. In the country, ice chests are not so commonly in use, so milk and food stuffs are allowed to stand around, and at room temperature become a culture medium for the bacilli.

Tracing the cause of an outbreak of typhoid fever, we must remember that the bacilli can live in the upper layers of the soil for many months, and in some food stuffs, especially sour milk; it can also be carried from one place to another by clothing. Although much has been written on the tenacity of typhoid bacillus, outside the body, under dry and moist conditions, and the possibility of its conveyance to the individual in dust, etc., it is highly probable that practically all cases occur either by direct accidental conveyance from typhoid patient or patients to those in immediate contact, through articles brought to or into the mouth, when infected by the typhoid patient.

The incubation period when infection has taken place varies generally from eight to fourteen days, sometimes longer, during which time there is a feeling of lassitude and inaptitude for work, headache, and a slight rise of temperature. Soon other symptoms appear with aggravation of those already observed. If previous cases have appeared in the neighborhood, it makes diagnosis easier. In doubtful cases, the Widal test and the Diazo reaction must be made use of, but the diagnosis is frequently possible with-

out these aids, particularly where the symptoms are typical. When the fever has reached its height, the temperature will range from 102° to 105° F., the pulse is rapid (from 100 to 110), full in volume, but of low tension, and often dicrotic. The tongue is coated, and the abdomen slightly distended and tender. Unless the fever is high, there is no delirium, but the patient complains of headache, and there may be mental confusion and wandering at night. The bowels may be constipated, or there may be two or three loose movements daily owing to the catarrhal condition of the intestinal canal. Towards the end of the first week the spleen becomes enlarged, and rash appears in the form of rose-colored spots, seen first on the skin of the abdomen. Cough and bronchial symptoms are not uncommon at the onset. In cases of moderate severity, the symptoms become aggravated during the second week, the fever remains high, and the morning remission is slight. The pulse is rapid, and loses its dicrotic character; there is no longer headache, but there are mental torpor and dullness. The face looks heavy, the lips are dry, the tongue in severe cases becomes dry also. The abdominal symptoms, if present—diarrhea, tympanites, and tenderness—become aggravated. Death may occur during this week, with pronounced nervous symptoms, or, toward the end of this week, from hemorrhage or perforation. In mild cases the temperature declines, and by the fourteenth day may be normal. In the third week, in cases of moderate severity, the pulse ranges from 110 to 130; the temperature now shows marked morning remissions, and there is a gradual decline of the fever. The loss of flesh is now more noticeable, and the weakness is pronounced. Diarrhea and meteorism may now occur for the first time.

Unfavorable symptoms at this stage are the pulmonary complications, increasing feebleness of the heart, and pronounced delirium with muscular tremor; special dangers are perforation and hemorrhage.

With the fourth week, in a majority of cases, convalescence begins. The temperature gradually reaches normal, diarrhea stops, the tongue cleans up, and the desire for food returns. In severe cases the fourth, and even the fifth, week, and sometimes later stages may present an aggravated picture of those symptoms usually observed during the third week of the disease. The patient grows weaker, the pulse is more rapid and feeble, the tongue dry, and the abdomen distended. He lies in a condition of profound stupor, with low muttering, delirium, and subsultus tenderness, the urine and feces are passed involuntarily. Heart failure and secondary complications are the chief dangers of this period, although other symptoms may arise.

Concerning the treatment of typhoid fever, it is important, in the first place, to employ a nurse who can follow the doctor's instructions carefully as to diet, giving of medicine, and keeping the patient and surroundings in a hygienic condition. The room should be well ventilated, no furniture permitted that is not necessary. Bed-clothes, linen, utensils, should be kept clean; all discharges should be sterilized.

The diet is of great importance. We must feed the patient in order to keep up his strength, and yet not overfeed him. We must give him the right kind of food, because it is through indiscreet feeding that so many of the complications occur, especially in the latter part of the disease, when the appetite of the patient returns. Of foods, milk is the best, preferably diluted with lime water, pure water, or a little brandy. We can give of this food three pints in about twenty-four hours, but a variety is better, and other liquid diets can be substituted for the milk, such as albumin water, beef juice, clear consomme, all of which can be made palatable by the addition of fresh vegetable juices. One egg may be used beaten up in milk or water. This liquid diet should be continued until the fever has subsided, and for four or five days afterward, before solid food is permitted. This new diet is introduced in the form of zwieback, over which hot milk or cream has been poured; milk toast, soft boiled eggs, meat broths, or finely scraped raw beef., etc. All through the fever the patient should be given water freely, pleasantly cold, iced tea, barley water, or lemonade may be used to change about.

To reduce the temperature, cold sponging and bath. For sponging, the water

may be tepid, cold, or ice cold, according to the height of the fever. A thorough sponge bath should last from fifteen to twenty minutes. In those cases, where the full bath is too weakening to the patient, the sponging is a good substitute. When the full bath is used, the temperature of the water at the beginning should be about 80° F., gradually reducing it to 70° F. After this there will be a diminution of the fever by one or two degrees.

Medically, I would use antiseptics cautiously. Quinine can be given in small doses, especially in the beginning of the fever. Care of the bowels is of great importance. If there is constipation, an enema should be given, followed by a calomel purge. It is well to give an enema about every fourth day, then, if required, some light laxative may be given. The mouth should be kept clean by washing it with some good antiseptic. Absolute quiet is necessary, and food should be restricted. If there is collapse, stimulants and injection of salt solution are called for. For gas in the bowels, we should use the high rectal tube. The kidneys should be watched, and heart weakness looked for. Other complications should be dealt with according to indications. Much more could be written about typhoid fever and its treatment, but I have endeavored to give briefly only that which is of practical importance to the practitioner.

[Written for the MEDICAL BRIEF.]

Personal Observations on Stricture and Its Treatment.

BY A. C. STOKES, B. SC., M. D.,

Professor Genito-Urinary and Rectal Surgery in University of Nebraska; Chief Surgeon to Swedish Hospital.
Omaha, Neb.

Stricture of the urethra, clinically speaking, has all the pathological phenomena of an ulcer in any part of the body. An infected ulcer in some part of the urethra attempting to heal brings about, a leucocytic infiltration and consequently walling off of the infection, the extension of arterioles formation of granulation tissue, connective tissue, and contraction of same, producing the symptomatology of obstruction to urination. Stricture has this additional pathological feature, that it is always on a mucous membrane, which normally is dilatable to a certain extent, and which is used several times daily for the passage of urine. The ulcer is thus exposed not only to the ordinary infections of an ulcer in other parts of the body, but in addition the irritation of a chemical fluid like the urine. It is rather difficult to say just what effect the urine has upon the ulcer within the urethra, but that it has a bad effect there can be no doubt. We are quite well aware that inflammatory processes along the urinary tract are much more easily controlled the nearer neutral or bland the urine. Chemically considered, this blandness must mean that the urine is neither sharply alkaline nor sharply acid to the ulcerating surface. In other words, the bland urine produces slight effect on the inflammatory process in the urethra.

Experience has taught me that infective processes in the urethra, whether of specific origin or not, are augmented, first, by the presence of urine, and second, by the fact that the posterior urethra has no point of drainage, unless it drains upwards; consequently, infective processes will seek all possible points of entrance to glands, vesicles, and tubes of all kinds lining the posterior urethra. We should, therefore, expect that every posterior gonorrhea would produce to a greater or less extent ulcerating surfaces which are more or less chronic, the chronicity being removed only by the removal of the two chief causes, viz., the passage of the urine over the ulcer, and poor drainage.

Thus, the chief problems to be aimed at in the treatment of an ulcer, or the result of the ulcer, viz., stricture of the urethra, will be to remove the causes as nearly as may be. In other words, the removal of the urine from the urethra, and increased drainage, and this can be done only by an opening in the posterior urethra.

We have been taught by Thompson to divide strictures into two divisions: Those of large caliber and those of small—a stricture of large caliber being defined as one which will admit a sound as large as 15 French. Those of small caliber, which will not admit a sound as

large as 15 F. Of course, we must consider this classification as more or less arbitrary.

Treatment.—Uncomplicated strictures of large size are readily treated by means of sounds. As a general rule, the stricture yields readily to the passage of instruments. If not, it is always well to remember that gentleness and patience are better than force and speed. These strictures having been dilated a few times apparently lose their terror, and the symptoms disappear to quite a large extent. I should recommend dilating strictures of large size with the sound, passing it, perhaps, three or four times weekly, depending upon the reaction produced in the urethra. I am very partial to the so-called instillating sound. In this particular class of stricture the urethra is dilated by the sound and medicated as the sound is withdrawn. If this stricture is uncomplicated and there is no infection in the prostate, seminal vesicles or bladder, one can oftentimes very readily obtain an apparent cure. In most cases, however, if the urethra is studied carefully with the urethroscope and the prostate and bladder studied by palpation and cystoscope, we are likely to find complications. In this case it is necessary to treat the complications as well. And, in my opinion, the treatment of a stricture is really more a treatment of complications than of the stricture *per se*. I am almost inclined to think that C. Fenger, who is very fond of using the phrase "once a stricture always a stricture," is right. However, by dilatation as above indicated, through periods of time varying according to the character of the stricture, we obtain a symptomatic cure in a large percentage of cases, and I am convinced that such dilatation is the treatment par excellence for strictures of large size.

We must not forget, however, that the complications may require other methods of treatment during that time. For instance, if the seat of gonorrheal infection is prostatic, we may have, in many cases, to do an external urethrotomy and cauterize according to the method outlined. If it is in the seminal vesicles, we may resort to Fuller's method of handling. One that seems to be more practical is Belfield's. I have been much impressed with Belfield's idea of opening the vas deferens and draining the seminal vesicles by the passing of fluids from the vas deferens into the urethra.

After all has been said regarding the different forms of drugs used in the urethra, the different forms of silver, the different solutions of copper, I always return to the use of silver nitrate in all forms of chronic discharge due to gonorrhea, due to stricture, and have secured better results from its use than any other form of medication. I use it in degrees of strength varying from one-quarter per cent to eight per cent, depending upon the inflammatory reaction which it produces in the urethra. I do not agree with Fenger and some of the other writers on this subject, who endeavor to make a differentiation of treatment by the question of whether there are gonococci present or not. The latter subject appears to revolve around the fact as to what the reaction of the urethra will be to various forms of medication. Astringents in chronic discharge, with the presence of stricture, have never appealed to me, and I have not obtained good results from them. In short, I may say that the treatment we use daily in our office in strictures of urethra of large size is slow dilatation by the use of instillating sounds and silver nitrate, feeling our way as to the strength of the nitrate by the inflammatory reactions produced in the urethra. If we can use eight per cent we use it, acting on the theory advocated by Keyes and others, that in all probability gonorrhea is cured, not so much by the drug action of the silver itself upon the gonococci, but by the inflammatory reaction in the urethra.

Strictures of Small Caliber.—These may be divided into:

1. Impassable strictures.
2. Strictures admitting only a filiform bougie, complicated by retention.
3. Resilient strictures.
4. Irritable strictures.

Impassable Strictures.—A stricture which is impassable to one man may not be to another. We must not forget that if there is one operation in surgery where skill is at a premium it is in passing a

stricture of the urethra. Just when a filiform bougie should be pushed forward, and when withdrawn, or when the entire filiform bougie should be introduced and when it should not, are questions that must always remain questions of judgment with the operator. I have seen cases where, during the first hour, it seemed impossible to enter the bladder, when suddenly the right move of the filiform changed an impassable to a passable stricture, and we were able to enter the bladder. There is probably no such thing as an impassable stricture; in all cases there must be an opening, but it may be so tortuous that only the most delicate handling of the bougie will enable it to pass. In these cases retention of urine almost always recurs and, sooner or later, the question arises, by what means shall we enter the bladder?

To find the urethra through perineal incision is, oftentimes, hazardous, if not impossible. We have left, then, the following methods by means of which we can withdraw the urine from the bladder, viz., suprapubic cystotomy, aspiration of the urine through the suprapubic region, and the possibilities of perineal drainage. The order in which these measures should be employed is frequently the most perplexing question. It would be an interesting thing to discuss in detail all of these various methods, but since this paper is to be one of personal experience, we will limit it to such. We have found very few cases, indeed, where the stricture could not be handled by the passage of filiform bougies and tunnel sounds. It has been our practice, where there is retention, to aspirate the urine through the suprapubic region. By the use of hot baths, rest in bed, slight doses of morphine, we have, in most cases, been able, in the course of six or eight hours, to enter the urethra. When this can not be done it is always best to make a suprapubic incision, I believe, draining the bladder through the perineum, and closing the suprapubic wound without drainage. By drainage the stricture becomes passable, and we may proceed either by internal urethrotomy and rapid dilatation or slow dilatation, beginning with small sounds. My preference is for internal urethrotomy with rapid dilatation, and I believe when this is done, and followed by the passage of sounds the results are better than by any other means.

2. *Strictures* admitting only a filiform bougie, complicated by retention, are, oftentimes, well handled by slow dilatation. I am not in favor of internal urethrotomy in strictures of small caliber, unless an external urethrotomy is done at the same time. The urine is continually passing over a wounded area, the resolution is only increased, and the internal urethrotomy offers new tissue for infection, which infection extends, so that the stricture, in time, returns with a much larger area of scar tissue, and a stricture that is worse. Therefore, in all strictures in which the bladder can be entered, if an acute infection does not demand external urethrotomy after drainage, we will lay down the principle that dilatation by sounds, or so-called slow dilatation, is the treatment par excellence.

3. *Resilient Strictures.*—These strictures are deceptive. At times they are very small and require the filiform to enter the bladder, and at other times quite large instruments may be passed. They are usually old strictures in which some excess, as sexual excitement, produces an increased flow of blood to the part. The stricture contracts, but dilates again rather more slowly than it contracts, so that in a short time the urine will pass without much trouble. In most cases these strictures require about the same treatment as those of larger caliber outlined above. One can not say that the results are particularly good, for although it may be possible, by the constant passing of sounds to the urethra, that portions of the cicatricial tissue may become absorbed, yet in our experience such things do not happen. Scar tissue of the urethra is the same as scar tissue in any other part of the body.

4. *Irritable Strictures* are those in which almost any form of treatment produces more or less irritability and pain. We are not quite clear as to their real pathology. Some have claimed the condition to be due to the presence of microorganisms; others, that it is a prostatic complication. One is hardly able to state, in so many words, just what the treat-

ment shall be, but it must not be strong medication. One of several things may result if active principles are employed. If active micro-organisms are present, one may expect an epididymitis or a vesiculitis, following strong medication. The use of the mildest forms of instillation is frequently all that may be employed in these cases. The acute inflammatory reactions in the urethra appear at times with such virulence as to almost equal an acute urethritis. I have had considerable success with salts of copper sulphate, about one per cent. This, we know, is quite contrary to the teachings of the men who claim that copper should never be used, except in old or very chronic inflammatory processes. However, the action of copper in the urethra is not as acute as that of silver nitrate, but the inflammation lasts longer. One can, oftentimes, reduce the irritability of the urethra by the use of copper, using it, perhaps, once or twice a week for the first two or three weeks, after which time one may return to silver nitrate or some other very active medicine.

I do not claim to have covered the whole ground in any way, but these few remarks are my own feeling rather than text-book ideas on the subject. To attempt to cover the question of diagnosis, pathology, classification or constitution of stricture would require too lengthy a discussion of the subject.

Practical Results in the Use of Cow's Milk for Children.

BY H. B. MILLER, M. D., PH. G.,

Professor of Materia Medica and Therapeutics, and Electro-Therapeutics in the Nebraska Medical College.
Lincoln, Neb.

Six years ago, after a thorough trial of the milk of Jersey cows, with unsatisfactory results, we began to experiment with the milk of other breeds of cattle, and today the most satisfactory results are obtained through the use of milk from Holstein stock.

Without going into the minutiæ, or the quantities of solids in general tests which have been extensively made by other investigators, we shall simply enumerate the results secured in different cases.

Case 1.—Two children, of healthy parents, that had failed to mature up to the ordinary standard at ten years of age, were put on a diet of Jersey milk. At the expiration of one year, there had been an increase of less than five pounds in weight. The surroundings of these children were of the best, and their other food was of the best quality and widest variety obtainable. At that time milk from a Durham cow was substituted for the Jersey. At the expiration of three months, the gain had been less than two pounds. The children were then placed on a diet (with the same general food) of milk from Holstein cows. At the end of one year, the average gain had been twenty-two pounds. Since that time they have been continuously on Holstein milk as a drink and general food. Their present weight is a little above the average.

Case 2.—A child, fourteen months old, was brought to me on account of its lack of growth. Finding the little one greatly emaciated, analysis was made of the mother's milk, and of the cow's milk which was being given at the same time. Mother's milk tested 3.5 per cent, and the cow's milk 6.4 per cent butter fat. Nursing was discontinued on account of the general health of the mother, and the fat of the Jersey milk reduced to four per cent. At the expiration of three weeks there was absolutely no gain in weight, and almost entire loss of appetite of the child. We substituted milk from a Holstein cow, yielding four per cent butter fat, and at the first feeding, nourishment was retained. By the end of the second month the child had doubled in weight, and since that time the little one has been continuously fed on Holstein milk and has gained normally in weight.

Case 3.—A child, four months of age, of German parentage (good health in both families), weighed eight pounds, which was one pound less than at birth. Mother's milk tested 1.8 per cent butter fat. Jersey cow's milk, yielding five per cent butter fat, had also been used for two months. We reduced the quantity of butter fat in the Jersey milk, and continued the nursing. At the expiration of

three weeks there had been no gain in weight, the child vomiting the greater portion of the nourishment taken. We substituted Holstein milk, carrying 3.2 per cent butter fat. The child is now eleven months of age, weighs twenty-six pounds, and is living on an exclusive diet of three pints of Holstein milk (without any modification) daily.

Case 4.—This child was five pounds below normal weight at the age of eight months, and would vomit almost half of the nourishment taken. It was fed on whole Jersey milk carrying five per cent butter fat. We substituted four per cent Holstein milk without any modification. At the end of six months the child is five pounds above the normal weight. Has not vomited any of its food during that period.

Case 5.—Twins, raised on Holstein milk, which had been skimmed after standing six hours. They have been exclusively bottle fed up to the age of eighteen months, receiving no nourishment except milk. Since that time they have been allowed a certain amount of other foods, and at the present time, at the age of thirty-five months, they weigh thirty-eight and forty pounds respectively.

Case 6.—Child was put on Holstein milk which was skimmed after standing twelve hours. At six weeks of age, the child weighed eleven pounds, a gain of four pounds from birth. During the next six months the amount of butter fat contained in the milk was gradually increased until the child was taking milk testing at six per cent. There was very little vomiting, and at eight months of age, the child weighed eighteen pounds. The butter fat was gradually reduced, and child returned to normal Holstein milk carrying 3.2 per cent butter fat. The gain in weight has been normal, and the child perfectly healthy.

Case 7.—Two children had been fed on milk which came from a dairy of poor sanitary arrangement, and we were unable to obtain a specimen of the milk to determine the quantity of butter fat. The children were suffering from great intestinal trouble, both vomiting and diarrhea being so frequent that the physician was unable to control it. In consultation, we advised the substitution of Holstein milk, carrying 3.2 per cent butter fat. Since that time the children have taken a quart of milk a day. There has been no medication of any kind, and the children have been perfectly healthy.

Case 8.—This child was the offspring of scrofulous parents. The grandmothers of the family had been feeding it Jersey milk, carrying 5.5 per cent butter fat, with the addition of brandy "for its colic," as they expressed it. Child was emaciated, and at the end of four weeks weighed two pounds less than at birth. Numerous prepared foods were tried, also modified milk, without any result. When the child was six weeks old, it was put on Holstein milk, 4.4 per cent butter fat. At the end of three months, child is normal in weight, and has not rejected any of its feedings.

It would be easy to enumerate an extended list of cases of children, and adults as well, that have been kept in good health, when the Holstein milk has been substituted. The best practical results we consider have been obtained from the use of Holstein milk, where the first, or largest sized, fat globules have been removed. The finer emulsification of Holstein milk, as compared with Jersey milk has been the theory started with in the use of Holstein milk as a food for infants. These results are absolutely practical, and we have the living objects to show for them. At some future date we will advance a positive explanation of the physiological reasons why Holstein milk is better than the milk from any other cow.

Two Good Remedies.

BY PROFESSOR FINLEY ELLINGWOOD, M. D.,
Editor "Ellingwood's Therapeutist."
Chicago, Ill.

Piscidia Erythrina.—This remedy was brought before the profession about fifteen years ago, as one that would probably control pain. It has not met all of the expectations of the introduction, but there is no doubt that its full value as an anodyne remedy is not yet known. It deserves a thorough, advanced study.

In its physiological action, it stimulates the salivary and cutaneous secretions, slows the pulse, and increases arterial tension. Its service by this influence, is followed by a reduction of the tension due to a slightly weakening influence of the remedy upon the heart. It at first dilates the pupils, but when the patient passes into a state of asphyxia, it causes contraction.

There is a question concerning its influence upon the irritability of the motor nerves, or upon the sensory nerve ends, but it certainly exercises a distinctly nerve sedative effect, and overcomes nervous excitability and reflex irritability. It is an anti-spasmodic of considerable power in mild cases. It does not cause dryness of the throat or mouth like opium, by suppressing secretion, neither does it induce constipation. It causes no distress in the stomach, nor does it decrease the appetite, nor the digestion.

In susceptible patients, it exercises an active controlling influence over pain, and is of much benefit in relieving general distress. There are some localities in which its pain-relieving influence is apparently much more readily exercised than in others.

As it does not oppose other indicated remedies, it may be given for the relief of pain or distress in conjunction with remedies that are specifically prescribed. It has been given with good results in inflammatory rheumatism, controlling much of the pain, and allaying gratefully the general irritability thereby induced. In the course of many inflammatory fevers, it has been given with good results.

I have obtained excellent results in the treatment of pelvic pain, whether the cause was in the reproductive organs or whether it was from renal or urinary disease. This has been especially true in dysmenorrhea, where there was ovarian congestion, as well as uterine displacements. In these cases, I have combined the agent with other specifically indicated uterine remedies, and have obtained superior results.

In the treatment of lung and bronchial troubles, those who have used it, have declared with considerable positiveness in its favor. It has been used in many forms of spasmodic cough, and especially that form of persistent cough which is due to irritation of the bronchial tubes, resulting in a constant inclination to hack, with more or less soreness of the bronchial tubes. In this form of cough it could be used in conjunction with bryonia, or if thought best, with small doses of ammonium chlorid. Five-drop doses, every two hours, have been administered with excellent results in both whooping cough and bronchial asthma.

One writer claims the remedy was most serviceable in the adjustment of fractured bones, or where the reduction of dislocations were possible without anesthesia.

Sulphurous Acid.—The field in which the most direct results from the action of this remedy are obtained, is that in which there are exudates, the development of which, induces toxines. I believe it to be as nearly specific for the removal of the exudates of diphtheria, as any remedy we have at our command. It has been proven also to be destructive to the exudates present in aphthous ulcerations of the mouth and throat, or of the nasal passages.

In the treatment of diphtheria, I have given from five to ten drops of the diluted acid, combined with two grains of sulphur, in a teaspoonful of simple syrup, or of mucilage of acacia, administering the dose every hour or two, according to the extension of the exudates.

It exercises both a local and a general influence upon this disorder, and even the most sanguine prescriber is apt to be surprised at the promptness with which the exudates will disappear under the action of this agent.

It is certainly destructive to the tubercular bacilli, but its application in a manner that will reach these germs is exceedingly difficult. The agent is especially indicated when, from any cause, the mucous membranes are dark colored or dry and dusky, whether the temperature be high or not, more especially if the tongue is coated a brown coat, is dry and pointed, has red edges or a red tip.

If the tongue is of a smooth red color or has a violet tinge, the internal use of this remedy will produce immediately satisfactory results. In the removal of exudates, these conditions need not be

considered, as the result depends largely upon the local influence of the medicine.

When from protracted disease there is gastric or intestinal fermentation, with an inclination to vomit yeast-like matter, or where there is an inclination to the development of gas, or where the fecal discharges are fetid, this remedy will serve an excellent purpose.

If the conditions of the tongue above specified are present, its action will be much more prominent.

I have been using this remedy externally recently for parasitic skin disease, and find that it destroys many forms of parasites. It is also available when applied to sore nipples, diluted either with water or glycerin, or to bruised or chapped hands, or chilblains.

[Written for the MEDICAL BRIEF.]

Mosquito in Disease.

BY R. S. MAGEE, M. D.,

Professor of Pathology in the Kansas Medical College.
Topeka, Kan.

The mosquito is a nocturnal as well as diurnal insect. It is also aquatic; can not live without water, nor can it propagate its species without water. It uses as breeding places still water. If you will examine the premises where there are any old broken bottles which will hold water, you will find that these make excellent breeding places for the mosquito. Mosquitoes have also gone into houses and used vases on tables where water has been allowed to stand until stagnant. Colonies have been found in such receptacles. Holes in trees where water will stand for awhile, old bottles, cisterns that are exposed and rain barrels are all favorite breeding places. The rain barrel is probably the most prolific source of the mosquito pest. The pitcher plant which grows in swamps is well adapted for a breeding place. One mosquito depositing her eggs in a rain barrel, will, in a few weeks, be the mother of several thousand mosquitoes. The laity call them wrigglers, but if your curiosity is sufficiently aroused to take a tumbler two-thirds full of water containing these wrigglers, and tie over it a piece of mosquito netting, and stand it on a window sill, where the sunlight will warm it up gently, and you will, in a few days, be rewarded by discovering on the mosquito netting half a dozen or more of full-sized mosquitoes. If you will take a larger jar and tie over it a mosquito netting, and on the top of which put some sliced bananas, you can feed the mosquitoes, and watch their growth and progress. They are exceedingly fond of bananas.

The eggs can be readily seen on top of the water, and have the appearance of black soot at first sight, but on closer inspection they will present a curved shape. If this sooty substance is pushed under the water, it will come back to the surface again as soon as released. Closer inspection shows this sooty mass to be composed of small segments, resembling pyramids, conical in shape. If you will take a pinch of this substance, put in water (filtered so as to exclude everything else), you will find in a few days that the water will be full of wrigglers. A mosquito will live all summer unless he meets with an accident. One mosquito, even though she lives a month only, may bring forth thousands of new mosquitoes.

The male mosquito is a lazy fellow who plays the part of a drone, and does not bite. The female mosquito can easily be recognized from the male from the fact that she does not have bushy antenna, or whiskers. They have a fondness for dark colors. I have made the experiment of putting inside of the incubator some dozen small boxes covered with as many different colored cloths, running from black to white, with the varying shades between of red, green, blue, etc., and observed that it was the exception for a mosquito to sit upon the light colors, while the black cloths were covered with them.

They do not travel far from their home or place of incubation, unless they are carried by the wind. The wind will blow them up from a swamp or pond near by, so that instead of blaming the pond for the mosquitoes, the breeding place is much more likely to be nearer the house. There may be an old rain barrel, or

bucket, or can of stagnant water, which is used as a breeding place.

The three varieties of mosquito are the culex, anopheles and the stegomyia fasciata. The culex is the common variety in this vicinity; it bites, but does not carry any disease. The anopheles is the malaria carrier, and the stegomyia is the yellow fever mosquito. The malarial mosquito can be easily distinguished from the culex in three ways: first, by its peculiar markings on its body. Second, by its resting position when sitting. Third, by the way in which it bites. The stegomyia is the most handsome mosquito of all, having beautiful silver band-like markings over its body. The carrying of disease by the mosquito was probably learned from the fact that the transmission of malaria to man was accomplished by the mosquito, and this led to the discovery of the malarial organism, and the yellow fever protozone. The yellow fever organism requires ten to twelve days after the sucking of the blood by the mosquito or the protozone to go through its period of incubation; a bite between this time will not transmit the disease. The malarial mosquito requires seven to eight days.

It is not now believed that there is a man-to-man inoculation in yellow fever, but that it is absolutely essential there should be an intermediate host. Patients have been permitted to sleep in the beds of yellow fever patients, to wear their clothes, to come in contact with their vomit, and not contract the disease, while ninety per cent of those that are bitten by this mosquito come down with the disease. The same thing is true of malaria; beyond a doubt the mosquito is the only source of infection in this disease.

The extermination of mosquitoes can be accomplished in three ways: First, by surface drainage, that is, the drainage of ponds and other bodies of stagnant water. Second, covering the ponds with petroleum; this method brings about extermination by destroying the larvæ. And, third, by stocking the ponds with fish.

[Written for the MEDICAL BRIEF.]

Memorial on Medical Language Presented for Consideration to the Rectores Magnifici of All German Universities Convening in Marburg, July 30, 1907.

BY DR. ACHILLES ROSE,

Adjunct Professor of Medicine at the New York Post-Graduate Medical School.
New York City.

RECTORIBUS MAGNIFICIS.

On May 4, 1907, the two hundredth anniversary of the birth of Linné was celebrated by the entire civilized world. The most prominent among the great merits of this reformer of science is that he has created a scientific nomenclature of botany, and thereby a scientific basis for botany itself. He solved the most difficult task to which any naturalist ever put himself: the arrangement of a very extensive material from a state of chaotic confusion.

On April 18, 1787, Lavoisier presented a memorial on the necessity of reform of chemical nomenclature to the Royal Academy of Sciences, in Paris, explaining the necessity of such reform in the following words:

"Onomatology furnishes the real instruments for the operation of the mind; it is important that these instruments should be of the best, and it is indeed working in the interest of science, for the progress of science, when we exert ourselves to improve our onomatology." Referring to the manner by which we acquire our knowledge in general, he points out the importance of a perfect onomatology for those who are beginning to devote themselves to the study of science. "The logic of science essentially adheres to scientific language. Science can not teach anything that is confessedly unscientific and false.

"In science we have to distinguish three things: The series of facts which constitute the science; the ideas which recall the facts, and the words to express the ideas. The word has to develop the idea, the idea has to embrace the fact: these are three impressions with the same seal. Since the words preserve the ideas

and transmit them, perfection in science is impossible without perfection in language.

"However true the facts may be, however correct the ideas developed by facts, only wrong impressions will be transmitted so long as the expressions by which they are communicated are not exact."

We shall honor the memory of these great men in the most dignified way if we make it our task to establish a scientific onomatology for medicine.

It is a fact that many designations in medical onomatology are incorrect, and therefore unscientific.

In language, everything is explained by logic or by history, which in itself is logic, and history affords an explanation of the corruption of medical onomatology.

In medicine there are many Greek and Latin words, on account of the fact that medical science originates in Greek and Roman antiquity. This classic element in onomatology has endowed medical science with an international character, and established a union of the various peoples to the best interests of science. It is a useful custom in medical literature not only to retain the terms which have come to us from the writings of the ancient Greek and Roman physicians, but also to coin new terms from the classic languages for new conceptions which were unknown to the Greek and Roman physicians of these ancient periods.

Most denominations are formed from the Greek, and there never was a language which admits of greater variety and greater distinctness of expression and style, of greater facilities in making combinations, than the Attic.

As the introduction of new appellations increased to convey new conceptions, more irregularities crept into our onomatology. In many respects the nomenclators of more recent times are the principal sinners by creating superfluous words, and disrespecting the laws of analogy and orthography.

The Greeks themselves are very reserved, very careful and exceedingly severe in admitting into their regular language a new formation which may be demanded by the exigencies of the times. Imagine how their linguistic sensitiveness must be offended, if in the foreign literature their eyes meet with linguistic barbarisms, invented and introduced by physicians who are quite unable to think in Greek. Numerous technical designations in medical onomatology are so incorrectly constructed that even the Greek must find it difficult to recognize the origin and significance of terms which are supposed to be Greek.

If nothing is done to check this evil, we are threatened by chaotic conditions which will aggravate the study of medicine, and render it a thankless task.

In 1821 L. A. Kraus published a critical etymological medical dictionary of names formed from Greek, but more particularly those which he had found to be wrong. Since the appearance of that book, complaints about the incorrect and hermaphrodite nature of many medical expressions have become general. The uninterrupted advance in medicine, especially since the introduction of bacteriology, made a necessity of a continuous production of new terms. Investigators and discoverers constructed new words without paying the slightest regard to grammatical requirements; they drifted into the habit of consulting a Greek dictionary, and welding together two or three single words, quite regardless of whether the new formations corresponded to grammatical rules or expressed the correct meaning.

Complaints about onomatological corruption form a standing part in modern medical journals. Virchow, in his Rector's address, called attention to this evil. Hyrtl, the greatest philologist among anatomists, published his Anatomical Onomatology, in which he characterized a large number of terms now in use as childish, absurd, and therefore unscientific. Henle tried to reform the anatomical onomatology. The German Anatomical Society has endeavored to establish a grammatically correct anatomical onomatology. A committee worked upon it for seven years without accomplishing the task the society had set itself. Indeed, all these attempts of earnest, learned men, commanding a thorough knowledge of classical philology, to improve upon our artificial language, were doomed to failure, and we shall presently see the reason why.

The presence of Greek and Latin terms in medicine made medical dictionaries a necessity. The oldest ones (the first of which that appeared in print was published in 1534) contained names taken over from the ancient Greek and Roman physicians, and in the course of time an ever-increasing number of Greek and Latin new formations were added.

And now we arrive at an important factor, to which nobody, so far as I am aware, has directed attention before me. The nomenclators whose new formations appear in our dictionaries did not or do not speak Greek; they knew or know only the written tradition, which means only part of the language, and did not take counsel with Greek contemporary physicians, who could have aided them. A most remarkable instance in this respect was the procedure adopted by the Committee of the German Anatomical Society, which worked for seven years holding conferences in Munich, Vienna, Goettingen, Strassburg, and Basle, but never in Athens. The Greek spoken to-day was left out of consideration; not even a look was cast into a modern Greek text-book on anatomy.

The fact of our having an unscientific medical language is to a large extent the fault of the philologers. They have tried to make us believe that Greek was a dead language, that the Greek as spoken and written to-day was a corrupt language, interspiced with foreign elements; men of great learning have made this assertion without knowing the spoken Greek of to-day. I may be permitted to adduce to you, Rectoribus Magnificis, the proof of the contrary being the case by presenting to you a book by the pen of Dr. B. Leonardos, *Ὀλύμπια* which has recently left the press. Just as it requires a German, or one who speaks the German language like a native, to evince true German linguistic intuition, it requires a Greek, imbued with the linguistic intuition of his language, to propose new formations of Greek words; and even such new formations can only be introduced into the scientific onomatology after having been approved or accepted by a large number of competent Greeks.

The international task of the University consists, especially in regard to medicine, in imparting to students a correct onomatology, and the fact of this being possible with the aid of the physicians of Athens I have demonstrated in numerous writings.

The language of an extinct civilized people, like the Baktrians, can only be communicated to posterity in one way, namely written tradition; the language of an uncivilized people like the Hottentots, again can only be transmitted in one way, and that is oral tradition; the tradition of the language of a living, civilized people, however, is two-fold: written and oral. These two forms of tradition exercise a mutual influence upon each other.

One of these influences is exercised by ancient lingual monuments upon later phases of the language, and the duration of that influence depends upon the extent of the ancient literature and the application which posterity brings to bear upon its study.

The study of a language like Greek should not be limited to the acquirement and investigation of one form of tradition to the exclusion of the other, because such limitation means an exclusion of one-half of the tradition, although both halves should be considered together as supplementing each other, in order to enable investigators to obtain a scientific understanding of both the old and the new phase of the language.

It seems reasonable to suppose that this should be clear to anybody, and that especially men of science would follow this rule in the study of a language. As a matter of fact, they do so in the scientific investigation of any other language except in Greek. In studying and teaching Greek, our philologers are unscientific; they only know the written tradition, call all words and phenomena in use to-day in Greece, but not contained in the ancient classics, modern Greek, and regard these words as not belonging to ancient Greek, although such words and phenomena are genuine, uncorrupted, and often unchanged Greek words of venerable antiquity. They do not know, and do not want to know, that the major portion of ancient Greek has percolated into the Greek of to-day by oral tradition only, and that the Greek thus orally communi-

cated is anything but modern Greek. The methods followed by these philologists are unscientific, faulty, and misleading. They have led astray the medical nomenclators.

By a simplification of the grammar, ancient Greek became the Greek of today; it was modernized. But with all this simplification, Greek remained what it was: the immortal language which developed from within, from its own elements, setting its face against the assimilation of foreign elements. It is the only language in Europe which requires no foreign words, and excludes foreign words.

Ever since men like Hatzidakis have published the history of the development of the Greek of to-day, there is no more excuse for the flagrant errors which are not only entertained by the world generally, but assiduously spread by philologists defaming the character of the Greek language of to-day. Nor is there any excuse for the fact that they attempt to kill Hatzidakis' writings by silence.

Men who have familiarized themselves with the Greek language and literature of the present day, are painfully conscious of the fact that otherwise scientifically educated men write on the subject of the Greek language of the present day without knowing it, writing in violation of all scientific principles, merely from hearsay.

Thanks to the preservation of the pure Greek language in the Greek spoken today, we may secure a scientific onomatology by taking counsel with our Greek contemporaries and their literature. For this idea I have unceasingly worked to kindle an interest ever since 1894.

In order to demonstrate how much could be done, even far away from Athens and without the aid of Greek colleagues, by simply consulting the current Greek medical literature, I have published in the MEDICAL BRIEF the commencement of Greek medical dictionary, and this simple presentation of a possible reform gave rise to an action which may well be chronicled as epoch-making in the history of medicine; the Medical Society of Athens took the matter into advisement. In its memorable meeting of April 14, 1907, under the presidency of Professor Geroulanos, it was proposed by Dr. Kallibokas to appoint a committee consisting of a number of physicians and a professor of philology, for the purpose of assisting in the reform of medical nomenclature. The motion was adopted, the committee was appointed, and the following names were enrolled:

G. Manginas, President.	A. Morelas.
A. Rose, New York.	I. Bistes.
Gabrielidis, Constantinople.	M. Oikonomakes,
D. Demetriadis.	P. Pampoukes.
S. Dontas.	I. Papalhesdoros.
A. Kallibokas.	S. Papasoterios.
I. Karabias.	B. Patrikios,
I. Kindines.	N. Petsales.
D. Kokkotes.	M. Sakorrhaphos.
G. Kosmetatos.	Th. Skases.
A. Kouzes.	Dem. Soteriados.
K. Lampros, Cairo.	B. Jouphexes.
K. Louros.	G. Trochanes.
M. Mankakes.	A. Iselios.
K. Melissinos.	I. Phoustanos.
V. Mermenkas.	S. Chomationos,
T. Mitautses.	An. Christides, Constantinople.

(To be continued.)

Paralysis.

BY A. J. HALL, M. D.,
McKenzie, Ala.

A few days since the writer had a case of paralysis in the entire left side. I thought the case was hopeless, but I went to work to accomplish something, and to my great delight I had him up and about in about a week's time, notwithstanding the case was complicated with functional heart trouble, causing great distress from dyspnea. I gave strychnine, nitroglycerine, alternating every three hours with digitalis. I also gave about ten grains of pot. bromide every six hours, and while I claim no originality of the treatment, I will say it surprised me in its quick and efficient work. Any of you, brethren, with such a case, try the remedy.

Diseases of the Breast.

BY ALFRED DE ROULET, B. S., M. D.,

Chicago, Ill.

Formerly Professor of Surgery and Diseases of Women in the Medical Department of Trinity University.

VI. TREATMENT OF CANCER OF THE BREAST.

In all cases of cancer of the breast where the disease is still sufficiently localized to render its complete removal a possibility, an immediate radical operation is imperatively demanded. Less radical measures simply entail the loss of valuable time and materially diminish the patient's prospects for ultimate recovery.

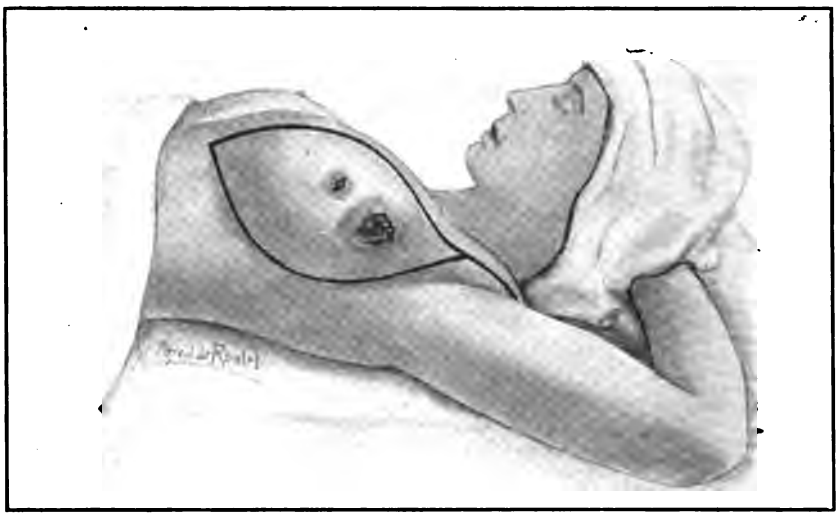

FIG. 1. Line of Incision in Radical Operation for Carcinoma of Breast.

In cases where the cancer has progressed to such an extent as to render the possibility of its eradication more or less questionable, as in those cases where there is a distinct involvement of the clavicular lymphatics, the indications for operation are not so clear. Very few cases which have reached this stage are cured, although some lives are undoubtedly prolonged by operation, and Halsted, of Baltimore, even reports a few cures. In cases of this class, I believe it is best to state the case frankly to the patient, and let her decide what she will do.

In cases where internal metastes have occurred, the eradication of the disease is clearly impossible, and radical operation is contra-indicated. In selected cases, however, it is permissible to remove sloughing tissues simply as a means of temporarily increasing the patient's comfort. In these inoperable cases, arsenic, the iodides, and mercury should be given freely, as they not infrequently tend to appreciably retard the progress of the cancer, although they are in no sense curative.

The application of the X-ray undoubtedly benefits many cases, and while I would not for an instant consider its use as a substitute for operation in operable cases, in inoperable cases it is certainly of decided value, even when it accomplishes nothing more than the healing over of superficial ulcerations, and the general relief of pain. In applying the X-ray, a medium tube should be employed, at a distance of from ten to twelve inches from the ulcer. The exposures should last from five to fifteen minutes, and should be repeated every second or third day. According to Eberhart, frequent short exposures produce better results than prolonged exposures at greater intervals.

The use of caustics in the treatment of cancer of the breast has little to recommend it, and much to condemn it, and, at the present time, is largely relegated to the advertising "cancer doctors." In preanesthetic days caustics were largely used as a substitute for operation, but

with the advent of general anesthetics they were promptly, and properly, abandoned by reputable surgeons.

In operating for cancer of the breast it makes very little difference whose particular technic is followed, the essential point being the extirpation of every particle of diseased tissue. This, of course, involves the removal of the entire breast, and the axillary and pectoral areolar and glandular tissue on the diseased side.

In Warren's operation, the surgeon begins at the lower angle of the wound, and works upward to the axilla, in this manner having the advantage of large, easy cleavage planes at the start, and the disadvantage of a bloody field of operation, and a certain loss of time in controlling hemorrhage.

In the Halsted operation, the dissection begins in the axilla, and extends downward to the breast. In this operation the dissection may not be easy as in the Warren operation, but the blood supply having been controlled in the beginning, the field of operation is comparatively bloodless, and the operator does not have to waste time in clamping or ligating divided blood vessels.

FIG. 2. Axillary Flap Dissected Up.

The Operation.—The patient is placed on her back with the arm abducted, the axilla shaved, and the entire field of oper-

FIG. 3. Breast Reflected and Pectoral Muscle and Fascia Exposed.

ation thoroughly scrubbed. If ulceration has occurred, the ulcer should be cauterized with either pure carbolic acid or the actual cautery and the ulcer packed or covered with gauze.

The incision should form an ellipse, encircling the tumor, the long axis being parallel with the direction of the fibers of the pectoralis major muscle. From the upper angle of the ellipse the incision is carried along the border of the pectoralis major to a point on the arm just below the point of its humeral insertion. (Fig. 1.) While it is desirable to be able to bring the edges of the wound together at the completion of the operation, it is not absolutely essential. Consequently, if the skin is infiltrated, a sufficiently wide area should be removed to insure the complete removal of all cancerous tissue, regardless of the subsequent closure of the wound. If the edges can not be drawn together with sutures, it is not a difficult matter to undercut the surrounding skin and slide the resulting flaps over the denuded surfaces. If for any reason this is not practicable, skin grafting may be employed.

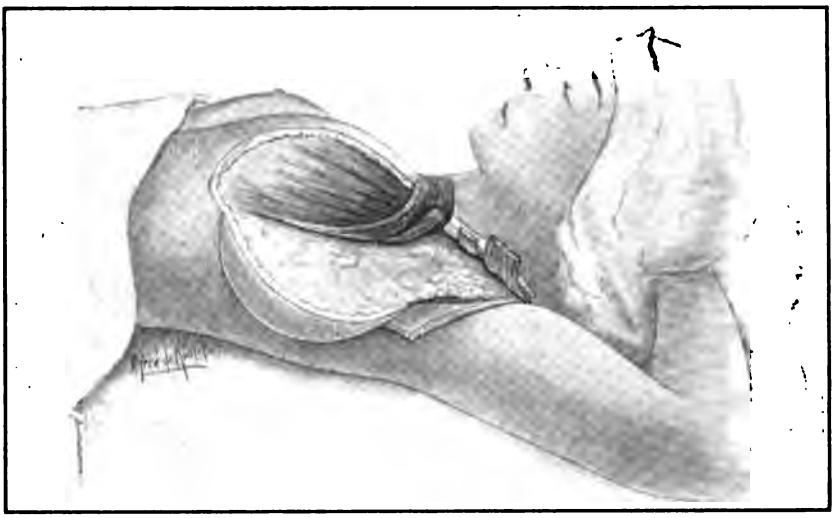

FIG. 4. Pectoralis Major and Minor Divided and Reflected to Facilitate Dissection of Axilla.

The primary incision is carried at once through the skin and fat, and a triangu-

FIG. 5. Dissection of Axilla Completed and Breast Ready for Final Separation from Thorax.

lar flap of skin is reflected well back toward the posterior axillary line. (Fig. 2.). The fat and areolar tissue lining this flap is dissected back to the border of the pectoralis major where it is continuous with the axillary areolar and glandular tissue.

The breast is next separated from the pectoral muscle, the pectoral fascia being stripped from the muscle and removed with the breast. It is not necessary to remove the muscle except in advanced cases, where it is involved in the cancer. The lymphatics along which the cancer spreads do not penetrate the muscle, but pass through the pectoral fascia, hence the necessity for completely eradicating this fascia.

After the pectoral fascia has been removed, the tendon of the pectoralis major is divided at right angles to the direction of its fibers, and the ends turned back. The next layer, consisting of the pectoralis minor, its fascia, and some loose connective tissue is now exposed. This fascia and connective tissue is dissected out down to the pectoralis minor, which is divided at a point slightly below its center, and the ends reflected. (Fig. 3.) The loose connective tissue under the tendon of the pectoralis minor must be very carefully and thoroughly cleaned out, as it is not only rich in lymphatics but is likely to contain lymph nodes already cancerous. This exposes the subclavicular structures, *i. e.*, the axillary artery, and axillary vein, which lies below and to the inner side of the artery.

The nerve trunks from the brachial plexus run parallel with but slightly above the blood vessels, while accompanying the vessels is a chain of lymphatics with connective tissue and fat. Beginning at the highest possible point under the clavicle, the axillary vein and artery should be exposed and stripped absolutely clean of all extraneous tissue down as far as the point of insertion of the pectoralis major. All small branches are ligated as close as possible to the main trunk, as they are exposed. In dissecting the axillary blood vessels it is best to hold the tissues in the fingers, and carefully push back the vessels rather than to attempt to hold the vessels and dissect off the tissues. The artery and vein being freed, with the left hand, sufficient traction being employed to slightly stretch the delicate fascia which attaches it to the chest wall. With a few sweeps of the wall, the knife hugging closely the ribs the mass to be removed is grasped firmly knife, this mass is stripped from the chest and serratus muscle.

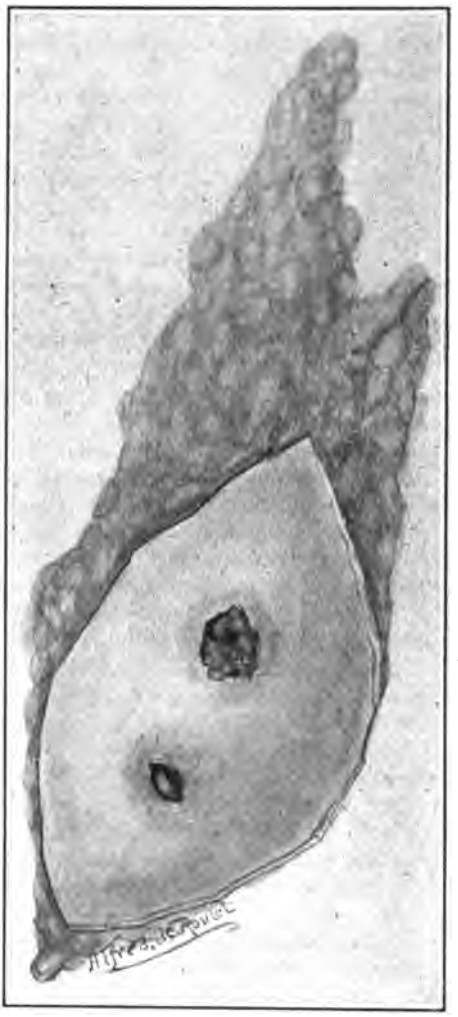

FIG. 6. Breast and Axillary, Fatty Areolar Glandular Tissue Removed En Masse.

Before reaching the junction of the posterior and lateral walls of the axilla, the original triangular flap of skin is drawn downward to facilitate the exposure of the connective tissue on the subscapularis, teres major and latissimus dorsi muscles. This tissue on the posterior ax-

illary wall is stripped off from within outwards, such subscapular vessels as are exposed may be tied before they are divided. The subscapular nerves may be divided or preserved as seems best to the operator, although it is probably better to preserve them. The entire mass, tumor, subcutaneous and axillary tissue is now removed in one mass. (Fig. 6.)

The ends of the pectoral muscle are now united with interrupted catgut sutures, and the wound closed. It is important that the triangular skin flap be applied closely to the fornix of the axilla to obliterate any dead space, and to preclude the possibility of the formation of a large mass of cicatricial tissue. This may be easily accomplished by crowding a large mass of gauze up into the axillary space, when the final dressing is applied. The after-treatment consists largely in making the patient as comfortable as possible. It is customary in most hospitals to redress these cases on the third day. In cases, however, where the patient is comfortable, where the temperature is below 99° F., and where there is no discharge or wound secretion showing through the dressing, I can see no reason for disturbing the dressing before the tenth day, at which time the sutures may be removed, and the patient allowed to get up. Early moderate use of the arm is rather to be encouraged, as it tends to prevent any subsequent restriction of movement.

During the operation, certain precautions should be taken to prevent, if possible, the reinfection of the wound with cancer. The dissection should, as far as possible, be carried out in healthy tissues, and every effort should be made to avoid opening up cancerous tissues. A knife or other instrument which has been in contact with the cancerous tissues should be sterilized before it is allowed to touch the healthy tissues, while unnecessary handling or manipulation of the tumor during the operation can not be too strongly condemned.

The mortality from the operation is approximately one per cent. The results of the operation are variable. Approximately forty per cent of all cases of cancer of the breast can be cured by radical operation, while probably sixty per cent or more of favorable cases can be permanently cured. Excepting in the most advanced cases, an operation which does not ultimately cure the patient will often prolong the patient's life from six months to three years.

The Well-Established Demand for Featural Surgery and the Attitude of the Profession Today.

BY CHARLES C. MILLER, M. D.,

Chicago, Ill.

A demand has been created for the skilled surgeon who can treat featural imperfections successfully, but the regular profession is taking no interest whatever in this field. It is most unfortunate that I must say this, for there is to-day in every large city the so-called "Beauty Expert," who is profiting greatly as a result of this demand, and if the general profession could only be interested in the subject, the cases which go to pay the advertiser good fees for poor services might be going to reputable practitioners, and they might be reaping benefits which they deserve.

Up to the present time, no surgeon in this country has manifested more than a passing interest in the important field of featural surgery, and I have found the great majority of the regular profession disposed to laugh at me when I tell them I find this field one of absorbing interest. This lack of interest will change shortly, and then we will find a body of men in this country devoting their attention to this subject, and I predict that so far as knowledge and skill is concerned, we will be able to enlist the most capable of the profession.

The newspapers and magazines have been developing the demand for featural surgeons for a dozen years or more, and there is no doubt that this is a permanent demand, for with the changes in the customs of the people, the importance of a presentable face is recognized.

The formation of the dimple artificially is one of the operations which the surgeon who interests himself in this class

of work will be called upon to perform in not a few cases. This operation is one which from the standpoint of justification we have comparatively slight grounds, and yet the operation is so simple, safe, and free from complications that I can not see the grave objections which certain men make to it.

Many featural imperfections are unsightly and repulsive, and no physician, except the most unreasonable, can object to their improvement, if such improvement is unaccompanied by danger to the patient.

The woman who desires a dimple formed is usually one who has more than the average degree of good looks, and, therefore, I can understand if certain

FIG. 1. Illustrating Location of Incision for Formation of Dimple, Dotted Circle Representing Area of Infiltration.

pedantic ones might object to "meddling with Nature," but, as I have said before, these women will set their heart upon having dimples, and as the operation is unaccompanied by risk, I have been unable to resist the urging of certain of my patients.

It is my practice in these cases to thoroughly scrub the cheek, and then after having the patient smile, select the point where a dimple should form under ordinary circumstances. This point may be found if the patient is caused to elevate and draw outward the angle of the mouth. I mark this point, and insert my hypodermic needle. With the hypodermic, the tissues should be infiltrated for a radius of about one-half inch. For this purpose about one-half drachm of a one-fourth of one per cent solution of cocain is used.

A very narrow-bladed scalpel is passed through the tissues, the line of the puncture being parallel to the long axis of the face. This puncture is only about one-tenth of an inch in length, and should not exceed under any circumstances one-eighth of an inch.

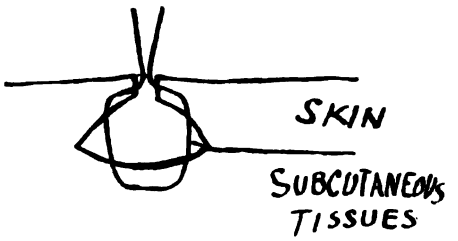

FIG. 2. Illustrating the Dissection Beneath the Skin in the Operation for Formation of the Dimple and the Manner of Passing Suture to Invert the Skin.

The point of the knife is carried into the cellular and fatty tissue of the cheek, and then these tissues are drawn up with a very small hook and snipped off. The amount of tissue excised is hard to describe, as, to a certain extent, this is a matter of judgment. The snipping away of the tissues beneath the skin should be followed by the out-turning of the skin, and the cutting away of a certain amount of the deeper layers of the true skin, so that the tissues will dimple after healing occurs.

No suture is passed in the simplest operation. The opening is covered with a very small piece of cotton, and then it is sealed with collodion. A slight dimple will be left when healing is complete, and if this is properly situated when the patient laughs or smiles, it will deepen

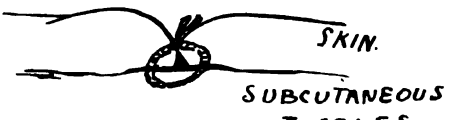

FIG. 3. Illustrating Operation for Formation of Dimple After the Suture Has Been Tied.

naturally, and the patient has, to all appearances, a normal dimple.

Where no tendency whatever exists for the tissues to dimple, the operation described may be insufficient, and it may

be necessary to turn the skin in somewhat by a suture. This suture should invert the margin of the skin, so that a dimple may be formed which exists whether the individual be smiling or not. The disadvantage of forming a dimple which may be present at all times lies in the fact that dimples of the cheek ordinarily show only when the individual laughs or smiles.

Relationship of Influenza and Malaria.

BY JOSEPH D. HARRIGAN, M. D.,
New York City.

Frequently we read of diseases as being related together, but seemingly, the full significance of such relationship fails to make the impression upon us that it should.

Although a kinship between certain of the epidemic diseases has been admitted by innumerable observers to exist, it has, apparently, been traced no farther than the surface.

It has usually ended by the acknowledgement of a family resemblance, just as one would trace the lines in a couple of photos, and has there and then yielded nothing further on which to base a claim of an actual, bona-fide blood relationship.

Take, for example, cholera and miliary fever.

Zuelzer states: "With regard to cholera, a certain relation between it and miliary fever has been accepted by some writers. In the earliest cholera epidemics, Hufeland called attention to their resemblance to the Sudor britannicus. * * *" Similar statements have been made repeatedly, thousands of times, with regard to "resemblances" acknowledged to exist between many varieties of epidemic disease.

But, instead of attempting to trace back the genealogy of these forms of disease, and thus eventually arriving at the basic ground-work common to them all, and which alone makes possible a "relationship," or even a "resemblance" between them, the most strenuous efforts of present-day observers is apparently directed towards the illogical and impossible task of proving that there is no relationship. This is plainly to be seen in the more and more arbitrarily drawn lines of distinction between forms of disease, that, as time goes on, become more sharply defined, and which tend to render the claim of "relationship," or even mention of a "resemblance," absurd.

If we would be successful in our efforts to establish and prove the existence of a relationship between certain forms of epidemic disease, it is of the utmost importance to compare the symptoms and pathological conditions found in one with those found in another of nearest "resemblance." If, as the result of this comparison, a sufficient number of symptoms or conditions are found to agree and to be identically the same in both, then we can regard these common symptoms, etc., as the basic ground-work of the two forms of disease, necessarily dependent, of course, upon one common cause.

These basic symptoms and conditions common to two or more forms, would constitute the essentials upon which the entire relationship must rest.

However, as we are well aware that there are wide variations in the forms of epidemic disease, it becomes of the utmost importance to compare more especially the *essentials* present in the different forms, and be guided by *their* agreement, rather than be misled by differences arising from disagreement of mere *accidentals*.

It would simply mean the extension of the very same principle that we make use of in our investigations of the varieties of intermittent fever.

Thus, as Hertz says:

"The form and the local affections of pernicious (intermittent) fever appear sometimes to depend upon external or individual causes. During the hot season of the year disturbances of the nervous system and of the digestive apparatus are most common, during the cooler season, those of the respiratory organs. Present or previous disease of certain organs, or *special influences brought to bear upon them*, may determine the localization of the symptoms."

Now, if this holds good, as it certainly does, with regard to the various forms of

intermittent fever, the exclusion of various other forms of epidemic disease from consideration as part and parcel of the same fever, merely on the basis of differences in accidentals, is absolutely unscientific.

The position held by those present-day observers, who, on the strength of presence or absence of the accidentals of disease, would manufacture new diseases for every deviation, is totally illogical and untenable.

If these diseases, such as intermittent fever, influenza, cholera, miliary fever, relapsing fever, etc., have so many characteristics in common as to be looked upon as belonging to the same family, it must be because of the presence of certain pathological processes common to them all, and, to all intents and purposes, identically the same.

The amount of confusion and error arising from classifying diseases according to their accidentals alone, is inconceivably great.

Take, for instance, again, the difference between miliary fever and cholera (certain forms).

The striking symptom in the one case is profuse sweating, in the other profuse diarrhea.

These are mere accidentals of the disease, readily comprehensible as applications of the principles of "points of least resistance," and of "parallelogram of forces." With all the remaining symptoms almost exactly identical, it seems absurd to consider these two affections as anything else but forms of the same disease. Were we to discriminate similarly between the forms of intermittent fever, on the basis of accidentals, some new and wonderful embellishments of our medical nomenclature might be anticipated.

The importance of adhering strictly to the essentials, in comparing diseases, in order to trace their relationship, is all the more necessary, in that, by a process of elimination we can pass through the series of complex developments, down to the simplest form, thus rendering much easier our quest for the cause of disease.

And it is only by getting down to the simplest forms and thoroughly mastering them in all their details that we can expect to accomplish the elucidation of their etiology.

Thus it is not by taking up the pernicious forms of intermittent fever that we are able to arrive at the clearest and most easily understood definable causes of the disease; it is by means of the study of it in its simplest forms that we can arrive at anything like a satisfactory result.

Then comparing this simplest form of intermittent with its nearest resembling "relative," we can very readily ascertain which of these two is the simpler, and, by the usual process of elimination, arrive finally at the basic essentials upon which we can feel reasonably certain the whole structure of "related" family diseases rests.

If now we can ascertain the cause of these basic pathological conditions, and find, by comparison, that it agrees with any one particular cause in the more complex forms which, in its essentials, the logically-deduced observations of many distinguished scientists would lead us to consider as pre-eminently correct, we would take a long step forward in our progress towards the solution of the intricate problem of epidemic disease.

The etiological factor of greatest prominence and importance in simple, ordinary intermittent fever, has been for ages considered to be an emanation arising from marsh lands, and known to us as marsh-gas, methane, or carburretted hydrogen. Now, if we were to take influenza as the nearest relative to simple, intermittent fever that we know of, we would expect to find as the principal factor in its causation some similar chemical to carburretted hydrogen, or at least, some preparation of hydrogen.

The fact that influenza is an extremely near relative of intermittent fever, is, in fact, one of the forms under which malaria in general manifests itself, and of which intermittent fever is likewise in itself only a part, may not appeal to one with the same full significance as it does to the writer, but let any one compare together the symptoms of both these diseases as it has been my privilege to do in recent issues of the BRIEF, and it will surprise him to find that in all the essentials they are identically the same.

In fact, influenza can be regarded in the light of such comparison, as the simplest form under which malaria manifests itself.

Influenza being a world-wide affection, it might seem at first thought impossible to accept with equanimity the statement that it is one of the malarias. But any one is at perfect liberty to prove for himself that the statement is absolutely true. Compare the essentials found in influenza with those of any of the malarial types. You will find that they will all agree—not, perhaps, in severity of operations—but they will agree nevertheless down to even the splenic, the hepatic, the enteric, the renal and other changes.

But even admitting that in the essentials influenza agrees with other forms of malaria, the identification as a malaria would be incomplete without a similar identification of the causative factors.

And, furthermore, inasmuch as influenza is a world-wide affection, the etiological factor in the production of the disease must be world-wide also.

In other writings upon the subject of influenza, I have made the statement repeatedly that this disease is due to the earth's passage through enormous masses of gaseous chemicals in space. These invisible clouds of gas are encountered in a manner similar to the encounters of the earth with the swarms of meteors with which astronomical history has made us all familiar.

These gases are the product of innumerable conflagrations that have raged throughout the universe in past ages, and, encountered by the earth in its career, impinge upon the earth from east to west.

This point alone in the theory of space-born epidemics harmonizes completely with the known facts regarding the course taken by influenza. Developing suddenly at different points of the earth's surface, it rapidly travels from east to west.

But the point which is of the utmost importance to us and upon which I wish to lay particular stress, because of its remarkable significance in connection with the subject of this article, is that relating to the composition of these enormous clouds of gas encountered by the earth.

We know that scores of most distinguished observers have attributed to marsh-gas or carburretted hydrogen the baleful property of producing malarias.

What should we expect to find as the principal feature of the gas clouds of space, if they cause epidemics of disease and if influenza, as can be clearly shown, be a malaria?

Why, certainly, some form of hydrogen.

But where does this hydrogen come from?

Where else but from the "new stars," those remarkable outbursts of flame in the heavens, that for ages have filled the minds of our astronomical confreres in the scientific world with awe and wonder, and which Bickerton, the celebrated Australian astronomer, claims to be due to the enormous friction resulting from the collision of two dead stars in space. "Partial impact" is what he calls this tragedy of the heavens whereby a new star is born.

The friction caused by these enormous masses on impact develops a temperature of millions of degrees, and the gaseous products of the resulting process are sent whirling through space in vast clouds.

This is what Professor Langley says of these "new stars" in his "New Astronomy:"

" * * * The fact is recognized, that, if we have observers enough, and look closely enough, the appearance of 'new stars' is not so rare a phenomenon. Every one at all interested in such matters remembers that in 1866 a new star broke out in the Northern Crown so suddenly that it was shining as bright as the Polar star, where six hours before there had been nothing visible to the eye. Now all stars are not as large as our sun, though some are much larger, but there are circumstances which make it improbable that this was a small or near object, and it is well remembered how the spectroscope showed *the presence of abnormal amounts of incandescent hydrogen*, the material which is, perhaps, the most widely diffused in the universe (and which is plentiful, too, in our own bodies)," etc.

Now whatever the reason for the tremendous flare-up in the heavens, it is a

fact indisputable, and it is also a fact that the spectroscope recorded the presence of vast quantities of hydrogen.

Enormous volumes of this lightest of gases, propelled by gigantic forces, must, naturally, having been ejected with a velocity above the critical, have escaped from the zone of attraction, only to wander in space in the shape of invisible clouds, until finally they impinge upon such bodies as our earth, bringing destruction and desolation everywhere wherever animal and vegetable life abound; thus we have our epidemics, as likewise our famines that go hand in hand with disease.

This great combustive process in space has happened probably thousands and thousands of times—if not millions.

Thus Professor Langley says "of these 'new stars' the examples may almost be said to be growing numerous, two having appeared in the last two years (1889)."

It can readily be seen that, with such processes going on for thousands of years, an inevitable encounter from time to time between these clouds and the earth must ensue. These gases must partake of the nature of volcanic gases, of which it must be recalled a considerable portion is made up of hydrogen.

But we all know that these gases are extremely deleterious to health and life.

Take, for instance, one of them—hydrogen sulphide. According to Professor Witthaus, this gas has a specific gravity of 1.19.

"*Occurrence*—In volcanic gases; as a product of the decomposition of organic substance containing S.; in solution in the waters of some mineral springs. * *

Toxicology—An animal dies almost immediately in an atmosphere of pure H_2S, and the diluted gas is still rapidly fatal. An atmosphere containing one per cent may be fatal to man, although individuals habituated to its presence can exist in an atmosphere containing three per cent. Even when highly diluted it produces a condition of low fever and care is to be taken that the air of laboratories in which it is used shall not become contaminated with it.

Its toxic powers are due primarily, if not entirely, to its power of reducing and combining with the blood-coloring matter. The form in which hydrogen sulphide generally produces deleterious effects is as a constituent of the gases emanating from sewers, privies, burial-vaults, etc.

These give rise to slow poisoning as when sewer gas is admitted to sleeping and other apartments, by defective plumbing, or to sudden poisoning, as when a person enters a vault or other locality containing the noxious atmosphere."

Mephitic air is what was held in olden times to be the principal factor in producing many diseases of an endemic nature. This air was considered as arising from the earth at different times, particularly at the time of earthquakes and producing widespread disease. Thus Noah Webster states: "I have suggested * * * that epidemic diseases may be sometimes occasioned by a vapor extricated from the earth * * * the sickness and death of fish are strong evidences of the truth of the principle." * * *

* * * In the account which Sir W. Hamilton has given of the eruption of Vesuvius in 1794, Univ. Mag. October, 1795, it is observed that "after every eruption of that volcano, we read of damage done by mephitic air, which, coming from under the ancient lava insinuates itself into low places, as cellars and wells near the foot of the mountain."

"Several instances happened after the eruption of 1767, of persons going into cellars and being struck down with this vapor, who would have died without assistance. This vapor, on an open field, subsides near the earth, being heavier than common air; but it fills cellars, wells and hollow places, so as to endanger life, and actually proves fatal to birds, beasts and vegetables; sometimes to men."

Numerous instances of diseases of epidemic nature, due to volcanic gases, could be cited, but for lack of space must be omitted.

Sufficient has been said upon the subject, however, it is to be hoped, to show that many of the most distinguished observers during past times were thoroughly imbued with the theory that many

of our epidemics were caused by mephitic air. Had they taken into consideration the fact that the foundation cause of all our malarias is, in all probability, carburetted hydrogen, and that the main chemical make-up of volcanic gases is hydrogen, it would, in all probability, have prompted them to compare the essentials of the two sets of diseases, and thus have caused them to investigate more closely these essentials that undoubtedly are the groundwork of the family relationship that must, because of a common etiological factor, exist between them.

And now if we of the present time go a step further, and finding the theories of a terrestrial origin for that greatest and most universal of the epidemics—influenza—totally inadequate for its elucidation, seek in space an explanation, we shall find in the volcanic gases through which the earth plunges in its career, ample and sufficient grounds upon which to base a thoroughly satisfactory conclusion.

Summing up the facts and theories in the matter, we find that:

1. "The various malarias have been considered by most responsible scientists as due to carburetted hydrogen.

2. "Influenza, judging from a comparison of its essentials, must be one of the malarias.

3. "Influenza, if it is one of the malarias, must be produced by a similar cause.

4. "The earth passes in its career through clouds of volcanic gases, which, as we all know, are made up principally of either free hydrogen or in combination.

5. "From the known effects of hydrogen, as exemplified in the malarias, we must expect to find widespread epidemics of disease similar to the malarias affecting the world at certain periods, due to this passage of the earth through vast clouds of this gas."

In conclusion, permit me to add that this theory satisfactorily explains the course of influenza from east to west; the simultaneous attacks at points widely separated from each other on the earth's surface; the variations in the accidentals of influenza, due to the variations in the atmosphere of different localities attacked; its undoubted relationship to the malarias in general; its periodicity; its connection with famines, meteorological disturbances, etc., as likewise supplants the mythological *influence* of the ancients, with a thoroughly satisfactory and adequate scientific substitute.

To those who might be tempted to ridicule a connection between medicine and astronomy, let me say that some of the greatest scientists of the past as well as of the present, recognized the fact that the human body simply reflects the Cosmos, is governed and is amenable to same laws that rule the universe in general; is part and parcel of it, in fact. Hence, any attempts to explain the various phenomena transpiring in the body and known to us as disease without bringing to bear upon the study a thorough general knowledge of, and application of, the same laws that maintain in a study of Nature, in all her beauty, both terrestrial and extra-terrestrial, must fail.

In terming the body a microcosm, the ancients chose well a name for what is, after all, but a reflection of the great Cosmos.

[Written for the MEDICAL BRIEF.]

The Relations of the Science of Chemistry to Medicine.

BY HOWELL B. GWIN, M. D.,
Nashville, Tenn.

CHEMISTRY ANSWERS THE FRATERNAL APPEAL OF MEDICINE IN DETERMINING THE PRESENCE AND TREATMENT OF POISONS.

The whole field of toxicology here opens to view. Poisons may be within or directed to the system. The analytical chemist has pointed out, in many ways, poison in medicines, in food, in the blood, urine, stomach and excretions, taken ignorantly or knowingly; and in the interest of benevolence or justice he has contributed to its exposure and suppression. How necessary that physicians have at their finger's end the antidote of poisons! I knew a case of poisoning in Virginia to which was promptly called a physician who, ignorant of the antidote, ran

to his office to consult his authorities, but on returning he found his patient *in articulo mortis*. It may be that in future toxicologists will, as specialists, share with physicians the responsibility of this practice—a responsibility fearful in legal cases, and moral as well.

CHEMISTRY, AS BY CONJUGAL BONDS, ENDOWS MEDICINE IN THE STUDY OF THOSE SUBSTANCES INVOLVED IN RIGHT LIVING.

This introduces the whole subject of hygiene. Happily, at this day, hygiene has gained strength enough to maintain an independent position as a science. To know and to counteract the causes of disease before they become effective is evidently the triumph of our profession. We wage unending crusade against ignorance of the laws of health and intemperance of all kinds which heretofore have been too powerful for us; but no crusade ever called forth more devoted warriors than ours. Diseases are but perverted life-processes. By time and rest, that innate *vis medicatrix naturæ*.

"Which hath an operation more divine
Than breath or pen can give expression to,"

reduces the perversions back again to physiological limits, and health is restored. We can not pass through the crowded streets and alleys of our cities without recognizing the proofs of this in the children's faces, and this dominant vitality gives us heart even where our work seems most hopeless. The effects of disease may be for a third or fourth generation, but the laws of health are for a thousand. To this beneficent law of our Creator we owe the maintenance, the beauty and form of our race in the presence of so much that tends to spoil and degrade it.

Remembering that our definition of medical science embraces "the prevention of disease," we remark there is a true medicine and a false medicine.

The true is that which is based on the unalterable laws of Nature; the false, that which is the result of ignorance, unconscious misinterpretation, or willful error, ignorance of Nature, unintentional misunderstanding of her laws, willful falsification of facts to subserve some temporary purpose. To winnow the one from the other, to acquaint with law and enjoin its observance, is our high prerogative. Once the imposter-priest was also the imposter-physician, and the patient was kept in the dark—the blind led the blind, and both fell into the ditch. Now, to both light is given, "knowledge is power," and the day dawns for the reign of common sense, illustrated by the Chinese race, which pays the physician when his patron is well and stops his pay when his patron is sick.

A celebrated physician, on retiring from a successful practice in Paris, announced that on a certain day he would recommend, as his successors, three eminent physicians. Everybody was on the *qui vive*. Many a physician hoped his name would appear in the list. The day came, the names were printed—they yet live—they are among

"The few immortal names
That were not born to die,"

they are "Dr. Quiet, Dr. Diet and Dr. Exercise."

The true chemist is not a meddler with "vital force," nor does he believe that "chemical force" should dominate it, nor that his substances have essential efficacy. He will not usurp the physician's prerogative. He refuses to assert with Paracelsus, that "the true use of chemistry is to prepare medicines." A student of nature, he will not rashly aid or resist it, but puts a check on the improper use of chemicals whose severe action he so well knows. And hence, Dr. Quiet as a chemist, prescribes rest for the repair of injuries. It is the eye of the comparative anatomist that discovers the greatest capacity for repair of injuries to belong to those animals in which the whole of life is carried on at the lowest rate, and in the nearest approximation to rest which is compatible with animality—in animals which breathe water. It is the eye of the chemist which explains this to be due to the scant percentage of oxygen, promoter of activity of function and rapidity of rate of vital processes. Now, if active respiration, if excess of oxygen, can be avoided in certain lesions of the body, a chief condition of its reparation pre-

vails. This is the office of sleep, Nature's sweet restorer.

The physical basis of the Sabbath is this chemical law that secures repair by the reduction of oxidation—a principle employed by the physician when he reduces the frequency and force of the heart's action. May not the increase of paralysis and other nervous diseases, be due, in part, to our fast living—to the neglect of Dr. Quiet's general and generous prescription?

Dr. Diet, as a chemist, as well as a physiologist, prescribes: First, air—Air is the medium in which all vital processes, both of plants and animals, takes place, and in which all human activity has its seat. The physicist gives it the properties of matter, and tells us that two forces ever act mightily on it—a centrifugal and centripetal—heat to drive it off forever, and gravitation to draw it down forever. The chemist describes its constitution. It is a mechanical mixture and not a definite chemical compound. Its chief constituents are oxygen and nitrogen gases, proportioned about one to four, almost absolutely constant. The other ingredients are fluctuating, but as essential as O and N. Its composition is thus represented: O 20.61, N 77.95, carbonic dioxide .04, aqueous vapor (average) 1.40, nitric acid, ammonia, carburretted hydrogen, traces =100.00.

Now, this air is kept pure by Him who "hath gathered the winds in His fists, who hath bound the waters in a garment." The animal and vegetable kingdoms mutually preserve the equilibrium; the animal receives the oxygen rejected by the "lungs" of the vegetable, and the vegetable feeds upon the carbonic dioxide rejected by the lungs of the animal. Oxygen is the active element of the atmosphere. It is the promoter of combustion, which, as already said, is simply a process of chemical combination. Burning and decay are but different forms of combustion. Oxygen is the "universal cement" by which the other elements have been joined together to form that grand and diversified whole which we call the earth. Life is an untiring builder, oxygen a fell destroyer whose energies are aroused by combustion (and decay). If, contrary to nature, oxygen be highly active where it should be only partially active, or passive, dissolution will occur according to the degree of its abnormal activity.

The chemist insists that nothing shall disturb this beneficent order of nature —that the air must be kept pure in all inhabited apartments and localities—that ventilation, drainage, antiseptics, disinfectants, must be employed to prevent both an excess of noxious gases and a lack of the necessary aqueous vapor.

Second, water—Water is *the* liquid of our globe. It forms the greater part of all organized bodies from the lichen to the oak, and from the polyp to man. No less than four-fifths of our bodies are water, which fact justifies that description that "the physical man consists of merely a few pounds of solid matter distributed through six pails of water." How a fatigued man craves water when much has escaped through excess of perspiration, and how intense is the thirst of one weakened by the burning of (proper description) fever!

Who can estimate the value of the cleansing, nutrient, stimulating, solvent or propulsive property of water? The chemist, who fixes its constitution and demands that it shall be kept as pure as nature provides from her brewery. As it holds in solution the substances from which the crustacese form their shells and the coral polyps build their reefs, as it fills the cavities of the rocks with gems and their fissures with useful ores, so it carries the elements of food through the system from which by chemical processes every cell of every tissue its own nutrition appropriates to construct "the human form divine."

Alas! how much sickness has been entailed upon families and communities by the use of water which has filtered through the refuse and filth of the kitchen, the privy, the sewer, and the cess-pool. The chemist is closely studying this matter, and from time to time voices his warning to and through the physician.

Third, food—This subject is too fertile for treatment in a brief space. Fortunately, its leading points are famil-

iar. Liebig and others have given and are giving valuable fruits of chemical study to the physician and the public. To avoid trichinæ, how shall our animals be fed, and how shall the meats be cured and packed? How shall the cattle plague be stayed? How shall we suppress food-adulterations? Shall a chemist be appointed to test our fertilizers and oils, and not our food? Shall we eat butter or oleomargarine? What kind of yeast powders shall we use? Shall every housekeeper use a lactometer? How shall we improve our cooking, partly a mechanical but chiefly a chemical process? How—the questions are too many. Answers are coming in from chemists. Liebig answers this question: How may we supply the want of alkali and ptyaline in children who are growing up without mother's milk? The diseases of the young are, in large part, preventable diseases. Sanitary laws must be known and enforced. No sanitary code exists—none so careful and detailed, like that imposed upon the Jewish people at the time of the exodus by the maker and builder of our frames.

Food is a chemical compound. The materials of animal food may be divided into three classes: Non-nitrogenized substances, such as starch and sugar; nitrogenized substances, like lean meat and eggs, and lastly, fatty substances, like butter. To those may be added a small proportion of earthy salts, found in almost all varieties of food that do not properly form a class. All three classes are necessary to the support of human life. Milk may be regarded as the type of animal food. It contains: Water, 87; casein, 4¼; butter, 3; sugar, 4¾; ash, ¾ = 100—sugar is non-nitrogenized, casein nitrogenized—and the fatty substances. Bread consists of starch, gluten and fat one to two. No article of food that does not contain all three of these substances can alone support life for any length of time; but different amounts are required under different circumstances, such as climate (an Esquimau takes and needs twelve pounds of tallow candles at a meal), physical activity, occupation, temperament, and for the right balance of one's food one is guided by experience, and in cases of decline or weakness by the skill and science of the physiological chemist. How necessary that the practitioner have an intelligent insight into all that is involved in this.

Fourth, Doctor Exercise is a Chemist.—(*a*) He walks his patient into the sunlight. *Whence the source of heat?* The sun. *Whence the source of force?* The sun. What untold chemical force in light! O blessed sunbeam, how do men slight thee, and refuse thy kiss upon their pallid cheeks and wasting forms, and the flash of thy healing within their chambers and cellars, prisons and infirmaries, swamps and forest-massed house yards? Light is the fountain of life; it is the symbol of Heaven; Heaven is health—"there is no night there." Truly, the light is sweet, and a pleasant thing it is for the eyes to behold the sun. Lavoisier, father of modern chemistry, said: "Without light nature were without life and without a soul; a beneficent God by it strewed the surface of the earth with organization, with sensation and with thought."'

(*b*) He bids his patient tread upon healthy soil. Thus is shunned the exhalations of swamps, of the debris of drifts, and of deposits of offal.

(*c*) He puts his patients to regular work. "Six days shalt thou labor" is a part of the fourth commandment as much as "Remember the Sabbath day to keep it holy." "We commanded you that if any man would not work, neither should he eat"—then work is necessary to life. The advantages of this are so obvious, it is unnecessary to enlarge. Finally,

CHEMISTRY STIMULATES MEDICINE.

In its incidental influences it exacts a mental stimulus. Its positive teaching tends, first, to free the mind from superstition, ignorance and error. It reduces a sagacious guess to the level of the prophecy of a quack. It purges medical teaching of much that is unchemical, and hence misleading, *e. g.*, it is even now assaulting the doctrine of "Catalysis" and seeking its banishment to the limbo of vanity, there to herd with Phlogiston (why should physicians yet "darken counsel with words" by speaking of the "phlogistic" treatment?) and

many other and younger as well as older unsubstantial Idola Theatri. It tends, second, to impel medicine to maintain itself as a science if its partnership with chemistry shall be on terms of equality. While giving due credit to other sciences, medicine must not permit them to fix a limit on the study of disease. In ages gone by Hippocrates had to vindicate the study of disease from the inroads of superstition; at the present day, we have to guard it against assaults of science (or "science falsely so-called"), and need to watch lest we betray it by accepting a too chemical or physical limit to our thoughts. It tends, third, to make the public more intelligent and reasonable, and law-abiding and appreciative. It is a relic of the dark ages to practice upon a man as if he were a block of wood or a blockhead. It is a blessed reformation to teach the sciences in our schools and colleges, needing yet to be perfected by the addition of experimental to theoretical teaching. Should not this science be honored by more thorough study in our medical colleges?

CHEMISTRY IMPRESSES A MORAL INFLUENCE UPON MEDICINE,

and in return receives this from medicine. In throwing a thousand side-lights on this complex being, man, possessed of organs by which alone he can work his earthly work, whether that work be that which he shares in common with the beasts of the field, or that through which he can enter into conscious relation to his unapproachable Creator, the chemist and the physician alike declare him to be "the paragon of animals, in apprehension how like a god, in action how like an angel."

Our mutual studies lead us in humility, reverence and homage (according to that Titan among scientists, Sir Isaac Newton), "to deduce causes from effects, till we come to the very first cause, which certainly is not mechanical," and all along we need to pray with Bacon, "May He grant us a true vision of the footsteps of the Creator imprinted on His creatures."

The Most Helpful Faith.

BY R. C. CAVE,
St. Louis, Mo.

The various theories of existence, however they may differ in their details, may all be classed under three general heads, viz.: Materialism, orthodox theology and divine immanence. Of these three, which gives the faith that is most helpful?

Materialism denies the existence of the spiritual, and holds that what is called soul is the result of a particular organization of matter. According to this faith, the universe is the product of blind force; "the world rolls round forever like a mill," and man is the "frail and feverish being of an hour," destined to sink into eternal nothingness. In such a faith there is nothing to incite men to courageously fight life's battles and bear the world forward on the tides of progress—nothing to inspire the hope by which the world's true work must be done. Instead of inciting to noble endeavor, it chills enthusiasm by declaring that all endeavor must end in nothing. It kills man's holiest aspirations by telling him they can lead only to bitter disappointment. It gives no basis for friendship and mutual service, save such as may be found in the helplessness and hopelessness common to the creatures of a day. It logically robs love of all spirituality, and makes it a mere animal passion which can not survive the loss of physical attractiveness. Surely, the faith which thus denies the existence of all that is spiritual and gives man nothing better than a charnel-house to hope for, can not be the faith by which to walk in order to attain the highest manhood.

We turn, then, from the hopeless faith of materialism to the faith of orthodox theology. This denies that the world is a blind machine, "grinding out death and life and good and ill" without "purpose, heart, or mind, or will," and teaches that all things proceed from and are governed by a supreme being whom it calls God; but its God is disappointing. He fails

to accomplish the good which he himself is said to desire, and fails to satisfy the most unselfish longings of his creatures. He gives life to millions of beings, most of whom he can not, or will not, save from endless torment. According to orthodox theology, as some writer has said, "the Creator really intended to do a good thing in the way of making the world and its inhabitants, but somehow everything has turned out badly. His plans have been balked, and, in sheer despair or anger, he has given us over, while he allows his saints or his saviors to act as wreckers, and gather in a little wreckage before the final sweeping away of the whole concern. When it urges religion as the salvation and hope of mankind, it means nothing more than the rescue of a moiety in the life to come." Such a faith may bring some sort of satisfaction to a man who fancies himself one of the moiety to be saved, and is so thoroughly selfish that he cares nothing for the sufferings of the millions who are lost; but I fail to understand how it can comfort and inspire any true and noble soul. Better than that, it seems to me, is the faith which denies a future existence, and, while depriving the few of endless bliss, saves the many from endless misery. I can see little that is ennobling in a faith that would influence man to be perfectly happy in the orthodox heaven, with the knowledge that countless thousands are being tortured in the orthodox hell.

But there is a faith which seems more helpful—more conducive to right living and noble character—than that which is found in the teaching of either materialism or orthodox theology. It is faith in God as a wise and loving Spirit resident in nature, and unfailingly making for righteousness; faith in a divine power working by and through natural laws in all things, and slowly but surely bringing good out of seeming evil; faith in this divine power as so present and efficacious in the universe that there can be no such thing as real failure anywhere. This faith recognizes the incomplete and imperfect, but sees in all things the tendency to perfection; and, amid the perplexities of existence, it relies, with unwavering confidence, on the Divine immanence who is leading all to good as the final goal. This faith gives comfort, hope and courage, and incites to the highest and best. Impelled by it, man, instead of seeking to save himself by believing dogmas, observing forms and relying on a savior's merits, will earnestly co-operate with the Divine Spirit in nature, and, through such co-operation, live most truly, come into moral accord with the eternal, and find the highest happiness.

Typhoid Fever.

BY J. H. MAQUARD, M. D.,
Clare, Mich.

I would like to give my experience with a family of seven members, all down with typhoid fever. The first patient was the mother of two children, who was sick with septicemia from premature confinement. She made a good recovery. Then followed the mother of the family, also the daughter, with two children, also the eldest son (who had prodromic symptoms). He began having a temperature of 104⅖° F., and on the seventh morning 102° F., and eighth morning 98½° F.

The mother had grave lesions of Peyer's patches up to the twenty-eighth day, with temperature of 102° F. The mother became so deaf that she could not hear a sound, yet she and the whole family made good recoveries. The family lived six miles from the city; yet I made forty-two visits to see the family.

If I fully outlined my treatment it would take too much space, therefore, I will only state that I kept the renal glands well toned up, and thus kept down uremic poisoning. I kept turpentine emulsion moving, heavily charged with subnitrate of bismuth. This had a healing effect on Peyer's glands. About the fourteenth day I gave large doses of quinine, alternating with strychnine, 1/32. I also sponged patients with alcohol four or five times a day. Owing to the bad sanitary conditions, I think I left a good record of recovery.

[Written for the MEDICAL BRIEF.]

Tapeworm — An Interesting Case, Both in Diagnosis and in Treatment.

BY GEO. F. G. MORGAN, BACH. DIVIN., M. D.,
San Francisco, Cal.

Yesterday I went out to the United States Marine Hospital, at the Presidio, San Francisco, to visit a medical friend and attaché of that very excellent institution. While there my attention was called to a very ingenious, positive, speedy and efficacious method of diagnosis of, and treatment for, tapeworm.

A sailor patient in the hospital mentioned to one of the medical attendants that he had been troubled with tapeworm, some of the evacuated segments of which he had seen in his feces, from time to time. This statement was reported to Dr. J. D. Long, passed assistant surgeon in the marine branch of the United States service. Dr. Long has lately returned from the Philippines, where he has made himself quite an enviable name as an expert on human intestinal parasites.

Dr. Long immediately took interest in this particular case. He closely examined and questioned the patient, but could discover upon him no positive signs of tapeworm.

Dr. Long was not to be thus easily thrown off the track of one of his special foes. He decided that if there were a tapeworm there should be eggs in the bowels. This he would find out by the aid of the microscope. Dr. Long obtained some fecal ejections of the patient, and put them under the microscope.

Lo! The eggs of the tapeworm, plainly to be seen. Therefore, the positive proof that the egg-producer was in the bowels. Now, the positive diagnosis having been made, the following intelligent, scientific and speedily successful treatment was adopted:

The patient received no food the first day, as a preparatory act. At about one P. M. of the second day the patient was given a gelatine capsule containing ten minims of chloroform, this capsule having first been heavily coated with salol. The object of this salol-coating was to prevent the capsule from being dissolved before it reached the intestine. By this expedient the whole force of the chloroform was thrown upon his wormship, which forced him to let go his hold upon the bowels.

About two o'clock the patient experienced a painful, burning sensation about the upper part of the transverse colon, a giddiness and dizziness of the head, obscuration of vision, and a marked fall of the pulse. This Dr. Long had expected and provided for by cautionary directions to the nurse in attendance, who was ordered to administer spiritus frumenti, one ounce, in case these symptoms came on, as expected. The case progressed finely.

A good dose of Epsom salts was now administered to the patient, and shortly after four o'clock of this (the second) day a copious evacuation brought forth his tapewormship entire.

It measured thirty-six feet and some six or eight inches long.

Dr. Long is to be congratulated upon the extreme simplicity and positiveness of his diagnosis, and upon the ingenuity, directness, rapidity and effectiveness of his treatment.

The Doctor will keep this case under observation, and in about one month from now will put the patient's fecal ejections again under the microscope. If, upon repeated microscopic examinations, no more eggs can be found therein, the cure will have been proven complete.

3440 Twenty-second Street.

[Written for the MEDICAL BRIEF.]

The Pharmacopœia as Seen by One General Practitioner.

BY J. LEVERETT, A. B., M. D.,
Yonkers, N. Y.

Why is not the United States Pharmacopeia more popular with the physicians? Why do not a larger proportion of prescriptions call for pharmacopeial drugs? Is there any good reason on the part of the physician why he should not use the pharmacopeia more? Is there any good reason for its lack of popularity?

When a student graduates into a full-fledged physician he has passed an exam-

ination in *materia medica*, and that *materia medica* is composed, principally, if not entirely, of pharmacopeial drugs.

The first few years in practice he is gaining experience, has time to study his cases pretty thoroughly, and is prejudiced in favor of the pharmacopeia. He gets familiar with certain drugs which, in this combination or that, appear to influence certain conditions for good. Certain others, which he has been taught to depend upon, have failed him, and a proprietary has seemed to turn the trick.

At the end of eight or ten years he has quite a pharmacopeia of his own, limited, to be sure, but composed of drugs which he feels that he can depend upon, some official, and non-official.

One of these is, perhaps, tincture of digitalis or tincture of belladonna, or tincture of aconite. He has gotten way beyond the text-book in these drugs, and his dosage does not depend on a memorized strength, but on the effect which he has been accustomed to get from a certain quantity.

Just now a revision of the pharmacopeia becomes authoritative, and he wonders why his prescriptions containing these tinctures do not have the effect he has learned to expect. He now learns that the strength of these tinctures has been materially decreased. He makes a mental note of this, and tries to arrange his prescriptions accordingly, but he has come to think of tincture of digitalis as an entity with certain effects, and not as a certain percentage of the crude drug, which in its crude form, has never entered into his experience and, therefore, he finds himself more or less at sea when writing prescriptions containing that tincture. What wonder, then, if he falls back on a proprietary which he has until now used but infrequently, but which he feels it is to the interest of the manufacturer to keep at a standard strength, and which, therefore, he can depend upon. But for the next changes in the pharmacopeia we are not to wait ten years. The druggists are clamoring for an annual revision, to be issued in a supplement. But, you ask, what have the druggists to do with it? Is not the pharmacopeia in the hands of the physicians?

For answer, let us look at the composition of the Revision Committee. Fifteen druggists and eleven physicians, and of these physicians more of them theorists than practical men.

Am I trying to block the wheels of progress? Not at all. A revision every year, if you choose, but make it in the interests of the physician. Let the changes be the adding of new preparations, and the cutting out of obsolete ones, but hands off the old standbys.

But why should the physician make a fetich of the pharmacopeia? We can see why the druggist should be interested, and why he should wish that prescriptions be limited to a certain list of drugs, but since when have the physicians been in leading strings, to be dictated to by any body of men, whether they are called a committee on revision, or a committee on new and non-official preparations?

The physician's business is to carry on the battle against disease, and to use the means, whether official or not, which will give the victory to his patient. It is the business of the pharmacist to see that the drugs furnished on prescriptions are what the physician expected his patient to receive, and it is not his province to try to tie the physician down to a certain set of drugs. The individual physician has to shoulder the responsibility in each case, and his hands should be perfectly free.

[Written for the MEDICAL BRIEF.]

Jaborandi.

BY JEROME D. DODGE, M. D.,
Collinwood, Ohio.

Pilocarpus is the official name of the drug more commonly known as jaborandi. The dried leaves are mainly used. The plant is native to Brazil and Uruguay, in South America, is found in the West Indies, and has been successfully raised in Italy.

The pharmaceutical preparations are the fluid extract, tincture and "specific medicine." The alkaloid pilocarpine, in the forms of hydrochlorate, hydrochloride, hydrobromate, nitrate, acetate and phosphate is also used. The dose of these

salts is one-tenth to one-half grain; of the fluid extract, ten to thirty minims; tincture, one to three drachms, and of "specific medicine" we add from ten drops to a drachm to four ounces of water, and give a teaspoonful of the solution every one-half to three hours, as indicated.

Jaborandi and pilocarpine have an effect almost identical, which is profuse sweating and salivation, in sufficient dosage, due to action on the glandular system. It sometimes increases the flow of milk in nursing women. On the pupil of the eye, pilocarpine acts as a myotic or contractor in the strength of one to four grains to the ounce, and is often employed for this purpose.

Pilocarpine is the physiological antidote to atropine and agaricin.

A telephone lineman was once brought into my office suffering from an overdose of atropine which he had taken by mistake. He afterwards told me that he took about half a teaspoonful of a solution which his doctor, later, told me was of two per cent strength. Luckily, it was taken on a full meal and within the hour I saw him. It required two men to support him while coming into the office. He acted precisely like a man suffering from an overdose of hyoscine, trying to pick things out of the air and muttering incoherently. I evacuated his stomach thoroughly and gave him pilocarpine hypodermically, and strong, hot coffee to drink, but he soon lost consciousness. His breathing and pulse became natural after a time, and in the morning he was well recovered.

This drug is said to act as a powerful stimulant to the growth of the hair, whether it be applied to the scalp or taken internally, and the new growth is often very dark in hue.

Hypodermically, pilocarpine is employed to remove opacities in the vitreous humor of the eye, and for the relief of thickening of the tympanic membrane.*

Dr. Kent O. Foltz, in *Dynamical Therapeutics*, says that he has found no remedy that causes such rapid absorption of non-organized vitreous opacities as jaborandi. He prefers the oral use of jaborandi to pilocarpine hypodermically. He states that "The use of jaborandi has given good results in tobacco amblyopia." In rheumatic iritis he has had splendid results from its use. In optic neuritis, detachment of the retina, choroiditis, and in atrophy of the optic nerve, the drug has given him good results. In iritis, from any cause, he finds it useful. In syphilitic diseases of the middle ear, in connection with specific treatment, he uses it with good results, both in relieving tinnitus and improving the hearing. In nervous deafness and that following diphtheria and scarlatina, he finds it useful. He has found it the most useful of remedies in treating non-suppurative otitis media of the proliferous type, and also for the restoration of the ceruminous secretion. Its benefits are produced by the increased secretion in the aural cavities. He finds it especially valuable in tinnitus aurium, and this action of the drug is confirmed by Dr. Lyman Watkins. It is indicated in dry conditions of the ear. It has been used, with care, in cardiac and renal dropsy. It has removed serous effusions from whatever cause, and is of value in asthma, bronchitis, albuminous diabetes, chronic rheumatic affections and puerperal septicemia, when no contraindications exist. "It is so powerful and certain in its diaphoretic action that it has taken rank as the most reliable of the remedies of its class."

Pilocarpus has been used successfully in diphtheria, erysipelas, diabetes insipidus, dropsies, aphthous sore mouth, poisoning, chronic parenchymatous nephritis, uremia, psoriasis and other dry forms of cutaneous diseases, and syphilitic affections. Care must be used lest it cause pulmonary edema.

"During the sudorific action of jaborandi the quantity of urine is lessened, but if it is given in divided doses, instead of acting as a diaphoretic and sialogogue it becomes an active diuretic."

"Experience with the sphygmograph, made at various periods during the action of the drug, has shown an almost complete asystolia, with a very considerable diminution of vascular tension. M. Robin is led to believe that jaborandi has an especial action upon the vasomotors,

*The National Standard Dispensatory — Hare, Caspari, Rusby.

which it paralyzes, whence results the cardiac asystolia and copious secretions of sweat and saliva."

*Because of this action on the heart it should be used with care in cardiac diseases lest it cause dyspnea, and even asphyxia.

Webster, in *Dynamical Therapeutics*, says that "the value of jaborandi in acute articular rheumatism is probably not equaled by that of any known remedy." The intense pain of acute articular rheumatism, he says, "may often be permanently relieved by it in an hour's time, and the inflammatory condition speedily dispelled." He advises: "In acute cases, when the pain is severe, twenty drops of the specific medicine in a swallow of water at a dose, and repeated in half an hour, if free perspiration or relief from pain does not follow the first dose. After this," he says, "from one to two fluid drachms may be added to four ounces of water, and a teaspoonful given every hour. When the pain is not very severe the large dose in the beginning may be dispensed with." He further says: "Under judicious dosage it is our most valuable arterial sedative, promptly controlling febrile action, lowering the temperature, and promoting normal secretion from the skin, lungs and kidneys, while the circulation is equalized and an agreeable sensation of coolness and comfort is imparted to the general cutaneous surface. It is thus valuable in all forms of fever not marked by great adynamia, and in inflammatory conditions its general effect is attended by amelioration of the local hyperemia of highly satisfactory character. We probably do not possess another as valuable agent in inflammation, attended by sthenic conditions, as this in the entire *materia medica*. In inflammatory rheumatism, from the most active forms, where the tissues are swollen to fullness of the skin, and the pain is excruciating, to more passive forms, where joints are swollen and stiff, but not exceedingly painful, there is nothing else in the *materia medica* like it for promptness of action in relieving the local symptoms. Under its influence, though here a few full doses may be needed, the most severe pain subsides, and swelling and redness are soon gone—not that there need be redness to indicate it, for many of these cases may be so subacute as to be pale and painless, though the joint may be swollen and stiff. Some of these patients may be able to be about their daily avocations, though complaining of swelling, soreness and stiffness of the joints. I find jaborandi to be the best prescription here. Since diaphoresis favors parturition, jaborandi has here a useful field. The feet should be made warm, and perspiration induced. The severity of the pains is often ameliorated, with rapid dilatation of the os and satisfactory termination of the labor."

In the treatment of acute colds, fevers, bronchitis, pneumonia or pleurisy, jaborandi may be combined with either aconite, veratrum, gelsemium, lobelia or ipecac; it may be made an adjuvant of acetanilide or used alone, according to conditions present. It acts as a depressant and should not be used in adynamic cases.

There are some fifteen species of the drug, two being principally used, and substitution of inferior species for the best is said to be common.

Tobacco Smoke—A Warning.

BY W. W. HOUSER, M. D.,
Lincoln, Ill.

I feel moved to sound a note of warning in regard to a source of infection which I have not yet seen referred to in all the many "danger signals" sent out by any of the learned professors, boards of health, or other experts.

I refer to smoke, and more especially to tobacco smoke. I believe all agree that smoke is minute particles of carbon, resulting from incomplete combustion.

There is no good reason why these floating particles of carbon should not be carriers of innumerable germs of consumption, pneumonia, influenza, etc.

Many smokers are infected with consumption, pneumonia, influenza, and other infectious diseases peculiar to the nose,

throat and lungs. The very passages these little carbon balloons are made to travel in the almost universal habit of smoking, and we are all compelled, on the streets, in the cars, depots, hotels and all other public, and many private places, as well, to take this same smoke, second handed, and probably disease-germ ladened from some badly diseased and infected mouth, nose, throat or lungs, and breathe it into our mouth, nose, throat or lungs. So why should this not be a most fruitful source of infection.

And, if the ordinary consumptive is to be kept off the streets and out of the schools; why should not this other walking source of distributing infection be suppressed.

It is revolting enough to know that in place of inhaling pure life-giving, vitalizing air, to which we are all entitled, you are taking into your mouth, nose, throat and lungs the exhalations from some dirty, black mug, you have just passed on the street, to say nothing of it being ladened with deadly germs, liable to lead you into a lingering and loathsome disease to your death.

The dust theory of conveyance of infection seems to be well established. So, if it is true that the deadly microbe is floating around promiscuously in the air, what is more reasonable than that tobacco smoke should become loaded with them in its passage through the air, even if it was free of them when it left its human chimney.

To me it is an unaccountable inconsistency for ladies, as well as gentlemen, who would think it an unpardonable offense against table manners to help themselves to food with the knife or fork with which they are eating, to sit in a room filled with tobacco smoke directly from other people's mouths, and when asked if the smoke is offensive, promptly reply, "Oh, no, not in the least."

If that is not "straining at a gnat, and swallowing a camel," hair, hump, bad smell and all, then I am no judge of good taste.

My plea is that no person has a right to contaminate the pure, God-given air, with a substance as offensive, as foul, and as disease producing as is tobacco smoke?

The Present Status of Medical Practice.

BY W. T. MARRS, M. D.,
Peoria Heights, Ill.

When the Pharisees of old claimed to have a corner on all the religion in the world at that time, they set a pace which has ever since been followed by many people in religion and medicine as well. It should be remembered that the two went hand in hand until modern times, and were under the dominion of soothsayers and the priesthood. It is unfortunate that neither subject, with all our learning, can be made clear by tangible demonstrations. Hence the diversified opinions and practices of those things that concern man's spiritual and physical welfare.

There is today as much unrest and uncertainty as to the correct management of disease as there was even a few centuries ago. The writer is not unmindful of the fact that the treatment and prevention of disease has made some few strides of which the profession may justly feel proud. But that medicine has not gone forward in a general and convincing way, is evidenced by the great and ever-growing number of physicians and "curers" of different faith. The brevity of this article precludes more than a cursory glance at a few of these. In referring to them I am, in some measure, guilty of uttering platitudes and oft-told tales.

Recently I read a little osteopathic literature, and from it, together with what I have from time to time picked up, my opinions on this subject have become more crystallized than ever. I am at a loss to understand how these astute gentlemen can find so many depressed ribs, dislocated vertebræ and anchylosed bones in general; so much osseous tissue impinging upon nerves and other soft but vital structures. Here is a bit of argument that is, I think, incontrovertible: If a bone, say a vertebra, is turned crosswise and fastened down by the adhesions of years, it seems to me to be a Herculean feat to straighten it around by manipulative procedures. Osteopathy has a

fair measure of success, but I'll wager my meager summer's wages that it is not due to the prying into plumb of misplaced ribs and vertebræ. The spinal pummeling, leg-pulling and general massage quicken the circulation, and perhaps materially affect the process of nutrition and repair. These things being tangible, a strong suggestive influence is brought to bear upon the patient's mind. This factor should ever be borne in mind. To heighten it, this class of physicians are usually men of refinement and erudition and their pleasing personality, coupled with their exorbitant fees, cause them to be looked upon with much favor.

The homeopathic parodox of what will make a man sick will likewise make him well is about exploded. Intelligent men no longer give the infinitesimal potencies with the idea of getting results from the remedies, *per se*. The writer has demonstrated the inertness of many of the little pills by swallowing them in considerable quantity. The homeopath is usually a scholarly physician, and is a good surgeon. When he wants the patient to know that he is taking something our homeopathic brother departs from the absurd Hahnemannian laws, and does not give a medicine produced by diluting a drop or grain of some drug in a barrel of water. As I have before pointed out, the homeopath very carefully searches out symptoms, and directs the treatment toward them. The patient associates his symptoms with an alleged specific, and thus the *cure idea* is better established in his mind.

Among the numerous irregular physicians and healers we may mention vitopaths, vibrationists, psychotherapists, Christian Scientists and faith and mental healers. Among this class the Christian Scientists seem to be gaining ground, and have more devotees than ever before. In fact, all these dispensers of healing succeed in bringing a fair measure of relief to all their patients who are ill from ailments that are non-surgical in character, the underlying cause being that they arouse their patients' subjective faith. The fact that I wish to emphasize in this connection is that the agency of the mind is significant in all cures, no matter what system of medicine is employed. Psychotherapy and suggestion should not be made a hobby, but it is a matter that deserves more general recognition from all physicians.

Why are there so many followers after strange gods in matters medical? Why can not those who sail under the "regular" colors adopt all that is good from the various schools and cults and eliminate everything that is useless or questionable? Our thousands of new remedies and rather complex surgery put our profession today on tentative grounds—the laity call it guessing. We have faced about on so many lines of treatment, introduced so many fads and so much quasi-science, to say nothing of the needless operations and "exploratory incisions," that many people have, in self-defense, turned to more benign methods. This condition would not prevail if we were more unified; and we would be more unified if there were fewer authorities (?) foisting their ideas upon us each year.

This, then, in brief, is the situation confronting us at the present day. Not a pleasant one to contemplate, it is true, and it will require eons of time to correct it. Prejudice and conceit should find no lodgement in the minds of true physicians, and the education of the people along medical lines should keep pace with scientific research. Education, and not legislation, is the only means whereby we may hope for a betterment of the medical status. The people are incapable of acting wisely on these matters because of the conflicting and chaotic opinions among those who profess to know.

These remarks are not prompted so much from a spirit of pessimism as from that love which chastiseth.

The Dispensing Problem.

BY CHARLES E. BUCK, M. D.,
Boston, Mass.

Who shall dispense the medicine? Who shall hand to the anxious patient the balm for which he has paid his money, and from which he justly expects relief from his suffering? This subject has been jostled back and forth between pros and

cons for so many years that it seems as though it had become an almost lifeless, battered theme, and it is like a renaissance to call it to life again; but, battered and torn as it is, from the many jabs which it has received at the hands of all extremes of logicians who have toyed with it, there yet appears one or two lines of argument which have not been fully exhausted.

The subject is one which is very broad in its general scope, and infinitely more so in its specific aspects. Many factors appear which seem to constantly block the way to a satisfactory solution, and it hardly seems probable that one will readily appear, when the conditions which influence a physician in the conduct of his business, are, of necessity, so varied and potent. It does not really seem to be so much a matter of what one should do, as what one can do; and the consideration of the subject from this point of view would seem to furnish the most logical, if not most universally accepted solution of the matter. The location of one's practice, whether it be in the city or country, its proximity to a convenient base of supplies, whether it is scattered and requires long drives to cover it easily, or concrete and quickly reached from the office. The customary routine of the older predecessors, if they were at all popular, together with the personal ability in pharmacological lines, all have influential bearing on the case.

A city practice will admit of prescription writing much more readily than will an isolated or scattered country clientele, where the doctor must necessarily carry his remedies with him, for the reason that the country people have always had their remedies delivered to them in that way. Every other doctor has done so, and it is not always a safe procedure to disturb existing conditions, especially so when these conditions are not of a particularly evil nature.

Even though a physician may be so situated, that he would like to dispense his own remedies, his training may have been of such a nature as to specialize his abilities otherwise, and he finds himself unable to work along these lines in a satisfactory manner. He has no alternative then, but to consult some of the many commercial *materia medicas*, of which he has many at hand, and get what consolation and aid from this source that he can, to aid him in h's dilemma. Oftentimes this procedure may prove fairly satisfactory, but, generally speaking, it is of too unilateral a nature to act as a reliable dependency, and the doctor who does so is apt to find himself a one-sided man in a many-sided profession.

There appears, also, another, and in many respects a most important factor, which should be considered by the physician, when he is attempting to make up his mind as to which course he will follow in this matter. It is the social feature, and to this he must have an exceeding care.

He should, first of all, be of such a temperament as will permit of his establishing his own course of business conduct and identity. This once established, he should not vacillate, unless he has occasion to do so of his own accord, when he should find that he is in the wrong in some of his dealings.

As to his relation with his pharmacist, that should be considered from the view of their own preferences, governed, of course, by the existing contingencies. If a physician is going into a new place to locate, and wishes to receive the co-operation of the druggist to help him increase his practice, there is no choice left him but to favor said druggist with all the prescriptions that he can consistently write. If, on the other hand, he finds it necessary to look more to the general good-will of his patients, and has the starch in his spine to endure the enmity of this same druggist, and his wife, and all her friends, why he can start in on a dispensing career, if he knows how. If he is in the city doing a transient office business, he should, of necessity, dispense. If he is in the country, where all the tact that he has must be exercised to keep everybody in good nature, he should keep in with the druggist; for just let me whisper from experience, that that town "poobah" can do things to a new doctor in the shortest space of time imaginable, which will make this young scion of Hippocrates weep in anguish.

In fact, it would seem that, view the subject as we may, there is only one con-

clusion upon which all can agree, and that is for those who still adhere to the older methods of prescribing, such procedure must be followed as best suits their individual needs.

Physicians practicing in a locality where conditions are ideal, both as to prices and collections, can not well advise those who are not so favorably situated; and, again, the conditions under which some physicians necessarily practice, do not admit of any choice in the matter; they must dispense whether they wish to or not, if they have any success with their cases.

It is a deplorable fact that the various schools of medicine are not awake to their duty in this matter. If they would only require a certain degree of proficiency in pharmacology from the applicant, in his entrance examination, or rearrange their curriculum so as to graduate men who are thoroughly familiar with standard United States Pharmacopeia preparations, and the indications for their uses, this subject would not be so much of a bugbear.

195 West Brookline Street.

The Diet Question.

BY O. A. PALMER, PH. D., M. D.,
Cleveland, Ohio.

In the consideration of this subject which has been discussed by men in all ages, many false conclusions have been reached, and these have been made the basis of many great errors which have gone down through the history of mankind and caused a great amount of sickness and death.

To simplify this subject as much as possible I wish to say that food is taken for the express purpose of supporting the body, and whatever the body needs should be obtained in the most convenient way, so as to prevent all extra wear and tear upon the organism, and thus preserve its energy, as a certain amount of energy or life force is used up in taking and preparing food for restoring the material destroyed during the activities of life.

I am a firm believer in the sacred records as to the origin of man. I believe that he was organized from the earth. The first man was named Adam because he was formed out of red earth, which, in Hebrew, is Adam.

It is not difficult to determine the elements constituting the human body, and there is no dispute upon this subject. An analysis made by one of the most careful modern observers shows that the body is nearly all water. A body that weighs one hundred and fifty-six pounds is all water but about twenty pounds, which is the solid matter of the system. The twelve inorganic salts and the four organic materials make up this twenty pounds.

All foods coming directly from the earth are the most likely to contain the ingredients necessary to support the human body, as they are from the same source; in fact, man can not be supported from any source except from foods that come from the earth, either directly or indirectly, and the only question in regard to this subject of diet is whether mankind shall exist on foods containing elements best prepared to support the body, or whether he shall live upon the material that contains a large quantity of refuse matter. All materials coming from the earth that do not undergo decomposition, such as wheat, oats, corn, nuts, etc., are the ideal foods, because they contain exactly what is necessary, with water, to support the body without sufficient refuse material to damage the organism.

The great question which has been discussed so much is whether man shall live upon foods obtained from the earth directly or indirectly, such as meats. Modern research has shown that all of the materials taken indirectly contain from twenty-five to forty-three per cent more refuse materials than those taken directly from it, that this refuse material becomes a source of great danger, and is the cause of much suffering. All meat products, whatever the method of preservation, are subject to rapid decomposition as soon as life is extinct, hence they become very unsafe food materials. I do not question that meat can be taken, and man can exist as he always has, but I do question its safety as a food.

It is sometimes said that meat is necessary for producing men of endurance and courage; that meat is an essential element of the diet of soldiers, but the endurance and bravery of the Japanese refute that claim. The Japanese, as a nation, are bright of mind, quick to perceive, active, courageous, strong to endure the privations of soldier life.

As the prime object of the diet is the support of the body, it is the height of wisdom to exclude all materials, from whatever source, that contain any elements of uncertainty and danger. It has been demonstrated that we have directly from the earth sufficient materials that have not the elements of danger contained in meats. Because meats have been used as food is no argument that they are valuable, for almost every kind of refuse material has been taken as food, and we are too well informed now to believe that all kinds of refuse materials should be used in making up the diet of man.

In illustration, many writers use the engine, saying that it matters not what is used for fuel; that any material will produce a certain amount of steam, fill the ash-boxes, and produce sufficient energy to run this engine. Any practical engineer will ridicule such illustration, for he knows the quality of the fuel determines the amount of energy or steam-force that can be obtained from it. Certain elements have more heat and more energy that others, and they should be used in preference to materials that have a large quantity of ashes and very little energizing force or ability to produce steam. Because an engine has been run with the poorest material on earth, is no reason why the present generation should be foolish enough to continue such practice.

I am not willing to admit that instinct is superior to reason, because reason is more than instinct, and when man is properly educated his reason will corroborate what he has learned are the best methods of diet. We say that animals are governed by instinct, they have no ability to go beyond certain articles of diet which are derived directly or indirectly from the earth. Man's instinct is altogether different from that of the animal. The instinct of the present generation is the result of long education of past generations, and has been greatly deranged by the methods of living that have been enforced from infancy up. The infant's instinct for milk and water is natural, and they are products it should have, and when properly given, are very satisfactory nourishment.

At this point I wish to discuss the main foods that supply the body. The air is one of the principal elements on which humanity exists. Man can live for weeks without solid food, yet he can not exist for even a few minutes without air, and the fact that more space is given to the handling of oxygen than of any other element that goes to make up the body is evidence that it is of greatest importance.

The structure of the lungs, exposing to the air one thousand four hundred square feet of surface which takes in this valuable food, the act of respiration being governed by stronger muscular action than that of any other food-handling act, are evidences of the great importance of this element. The lungs contain seven hundred and twenty-five million air cells, which should be constantly bathed with pure air. I can safely say at this point that no one will question that pure air is of first importance. That humanity has lived on impure air for a certain length of time, and in the filthy air of cities, homes and hovels does not disprove the fact that pure air is of first importance, and since no food is of value unless it is transformed by the energy of oxygen this life-giving and life-sustaining element is of first importance.

Food from whatever source is of no value unless thoroughly oxygenized. In the lungs the venous blood is purified, or, in other words, carbon dioxide and water are thrown out and oxygen is taken in. The majority of athletes of this country have died of consumption because their lung capacity was not able to oxygenize the materials needed for so strong a physical development.

The heart and lungs are indispensable in preparing food for nutritive material. Nature has endowed these organs with a large amount of untiring energy to carry on respiration and circulation. All are well aware what an effort is required

to check respiration. This wonderful force is exerted mostly upon inhalation, which is principally muscular, while exhalation is due to the relaxation of the muscles and the elasticity of the structures of the chest. If there is not sufficient muscular ability to take in enough air to oxygenize the food and properly cleanse the venous blood, perfect blood-building and transformation can not take place.

More attention should be paid to the development of the lungs so that they will have sufficient absorbing power to take in the necessary quantity of oxygen. It has been determined that from the diseased conditions of the air-tubes and cells of the lungs their absorbing ability is diminished from fifteen to forty per cent. Unless all of our food elements are perfectly oxygenized and the venous blood purified, perfect nutrition can not take place. In order to have normal nutrition we must have all the functions of the body in good working condition, the proper food well digested, perfect oxygenation and the proper elimination of all excrementitious materials. Any suspension of proper atmospheric influence certainly causes the first stage of disease which is devitalizing to all the tissues, thus preventing normal nutrition. Oxygen is of first importance in sustaining the human system, and when properly handled does no damaging work, but is always a building agent, preparing the body for its normal activities.

The second most valuable food agent is water. Since the greatest part of the human body is composed of this liquid, holding in solution all the materials that go to build the body, with all those that are injurious to it, the normal quantity and quality are of paramount importance. Perfect nutrition is impossible unless food elements are properly oxygenized and held in solution so perfectly that every cell can readily absorb what it needs to sustain its existence. Blood, like milk, contains eighty-seven per cent water, but this percentage should be sustained. If the quantity of water becomes too great, the excretory organs throw it off, but if water becomes deficient, the poisonous materials are not thrown out of the body, and the blood fails to nourish and sustain it.

Water is the most important of all the liquid foods, and it is the greatest tonic that can enter the human body. It assists in building up the organism, in repairing its tissues when worn out, it maintains the proper bulk in both the blood and tissues, rendering them soft and mobile. Water is the natural beverage of man, and is the only thing that slakes his thirst, cools his blood, whether in warm weather or in fever. Water is the only true food solvent, and promotes the circulation and accelerates the activity of all the excretory organs. It passes from a fluid form to that of vapor, and is the means of keeping down the body temperature, which would otherwise rise to a point dangerous to our existence.

Water should be used to the amount of six pints daily to supply that lost by the skin, kidneys and lungs, and should be increased to twice that amount in wasting diseases. Water is absolutely required for the secretion of all the digestive juices, saliva, gastric juice, bile, pancreatic fluid and intestinal secretions.

Modern research has demonstrated that pure, soft water is the only fluid ever intended for man's needs. Waters containing large quantities of salts of various kinds have to be handled by the different structures of the body, and in many instances are a source of damage. Because man has existed on water charged with all kinds of materials, both beneficial and harmful, is no reason, in the light of modern research, that he should continue their use.

The next most important food elements for the body are what may be termed mineral matters. Mineral matters are solid foods. These are alkaline and earthy salts which must come directly from the earth in order to be perfect in their action. In a man of average weight are seven and a half pounds of mineral matter, most of which is in the osseous framework. Mineral matters are absolutely essential to life. Without them man can not exist for thirty days, even if he takes all other classes of foods. He should take nearly one ounce, or about four hundred grains daily.

Iron, lime, soda and phosphorus are the most important minerals. Phosphorus plays a very important part in nutrition; it is very useful in the organization of the bony tissue, and is absolutely essential to all cell activity. The bones, brain and nerves are richly supplied with this element.

Foods are usually classified as hydrocarbons, carbohydrates and protein matters. The hydrocarbons, such as oils and fats furnish the heat and energy. The carbohydrates, such as sugar and gums, have very nearly the same action. The protein matters, such as eggs, peas, grains, gelatine and meats, to a certain extent, are tissue-builders. The functions of food are to supply the animal heat, energy for work, and the elements for growth and replacing of wornout tissue. The animal heat of the body is supplied by all foods containing carbon which is found in fats and oils, sugars, starches and some in the proteins.

The greatest difficulties in considering the diet question have been on the nutritive value of food. Modern research has furnished us a standard of value which is called the caloric. It is now understood that the digestion of food is essentially its combustion, and that the amount of heat evolved by the complete combustion is an index to its nutritive value.

In the ease and completeness of the absorption by the blood and general assistants vegetable foods show a much less loss of their food elements than do meats and eggs. In all instances they exceed meat greatly in ease of handling. For instance, in white bread there is four per cent waste, while in whole wheat there is five per cent loss. These statements are based upon the laboratory experiments of some of our state universities.

The next most important question is the daily amount of foods that should be taken. Professor Crittendon and Horace Fletcher have fully demonstrated that mankind does not need the amount of food that was formerly stated as the minimum.

This seems to be the era of the food crank. He expounds his doctrine to his friends and acquaintances. He lectures when he can get a platform and an audience. He writes earnestly and dogmatically when he can induce a magazine or a newspaper to publish his productions.

One of them says: "Eat no meat; man is above the dog, and the tiger." Another proves that cooking is an invention not in harmony with nature; only raw foods should be eaten. There is also the ardent advocate of a diet composed wholly of nuts. Then there is the cadaverous apostle of the fast; he regards appetite as a vice to be disciplined and regulated by rules. If all of them are right, there is nothing for mankind to do but lie down and die.

A Yale professor has had the rare good sense to take up this subject and experiment with it, not as a scientist might be expected to do, but as any clear-headed man not weighed down by book learning, would go about it. Nine healthy, normal Yale students were used in the tests, one of which continued for ten weeks after the rest of a vacation, and the other for ten weeks after a period of hard college work. The subjects of the experiment were requested to eat whatever their appetites called for, and as much as was required to satisfy them. The only order given was that they should thoroughly masticate the food and realize the taste of it to the utmost.

The results were surprising. At the end of each experiment it was found that the men had greatly decreased the quantity of food they wanted. Tests made before and after each experiment showed that their powers of physical endurance had increased from fifteen to more than one hundred per cent in spite of the fact that they had not taken any special physical exercise. They had improved, also, in physical strength and mental quickness. They were better men in every way than when they started.

The great Scotch writer once said, in answer to the question how we should eat, "Chew your food thoroughly, eat slowly, eat as little as you can and be comfortable; have a fair breakfast, moderate dinner and a very light supper."

There has been much discussion in regard to the best preparation of the different classes of food, also the varieties of food that should be taken together. Much

criticism has been lavished upon the modern methods of cooking. In many instances this is just. Whether to discard all methods of cooking and insist on taking entirely raw food as it comes from nature is still a question for discussion.

Some articles of food may be taken without any special preparation or cooking with as much benefit as if they were prepared by the most skillful cook of today. Other articles which need to be stored away for future use, must be carefully prepared for this condition, and when they are taken as food they should be in as near a natural condition as possible.

Modern cooking consists in applying heat and water and making up various mixtures in which the food value of the ingredients is often destroyed, and not infrequently the mixture is positively harmful. The securing of food is the chief business of the people of the earth. If all food be taken as nature intended, it will produce a natural healthy being. The elements that make up food should be changed as little as possible, as the supreme intelligence has prepared them as perfect as they can be.

Much of our food has always been taken without cooking, such as milk, cream, nuts, figs, grapes, pears, apples, raisins, dates, melons, cucumbers, olives, celery and olive oil. No one questions the advisability of doing this. It has been argued that all animals below man take their food raw, and enjoy better health. They have a digestive system adapted to this raw food, and are prepared to handle the kinds of food they need. For ages more than one-half of the staple articles of food have been cooked. We do not question that humanity could exist upon raw foods. The question now is whether mankind, whose digestive apparatus is adapted to cooked foods mainly could readily take altogether raw foods and be better than they would be with cooked foods. As this question has never been thoroughly worked out, it would be impossible to state at the present time what the use of raw foods would do. As palatability plays a great part in the taking of food, and as the present generation is accustomed to certain articles being cooked, such as meats, potatoes, vegetables and cereals, and as no one has demonstrated that proper cooking in any way seriously damages foods, it would look to be wisdom to continue cooking.

Because much of the cooking of modern times is absolutely injurious, destroying, to a great extent, the food elements and producing a harmful mixture, many writers and thinkers would swing back to raw foods only. It is the proper use, and not the abuse, of cooking that I am contending for. Because water drowns people is no reason why it should not be properly used for the benefit it will give us.

The following quotation is of value on this point: "In general I would say that all those foods which can be eaten uncooked and are palatable in that form, should be so eaten. There is little doubt that they are more valuable in their natural state than when cooked. Among these are nuts, fruits and some vegetables, together with milk and honey. However, there are some foods upon which man can subsist which, in their raw state, are not suited to the human stomach. Naturally these are better cooked, in which condition they are not only actually more palatable, but are capable of being more readily acted upon by the digestive juices of the stomach. Among these are beans, potatoes and other vegetables. To these might be added fish, fowl and flesh, if you are still carnivorous. Briefly, the natural palatability of a food, either its cooked or uncooked state, and your ability to enjoy it, should afford you ample guidance in this respect. No one is in a position to dogmatize on the diet question; even the cooking of cereals is a disputed point. Roasting of many foods is far more advisable than boiling, and steaming is fairly satisfactory. It would pay every one to study the subject of diet thoroughly, and decide each incidental question for himself."

Typhoid Fever, Etiology, Prevention, Treatment.

BY D. W. REED, M. D.,
Greeley, Colo.

The great physician said: "The poor you have with you always," and the same might be said of typhoid fever today, for it is sure to develop wherever people collect in large numbers, either in cities or camps, unless great care is exercised to dispose of all human and other animal impurities.

One of the direct causes of the disease is the *bacillus typhosus*, but the bacillus *coli commune* also has the power to produce the disease when it enters the alimentary canal in sufficient numbers. The germs enter the alimentary canal with the food or drink. They may enter the food and drink in several ways. First, water-sheds are polluted by animals, barnyards, etc. Second, sewers carry impurities into rivers, which serve as sources of water supply for cities lower down on the same streams. Third, boys often bathe in reservoirs outside the city limits. Fourth, in rural districts where no sewers exist, the surface closets are exposed to large swarms of flies, which carry the filth on their feet into the houses, where they light upon exposed articles of food; sometimes at the moment when it is being conveyed to the mouths of the people. This, I believe, is not a small factor in the causation of the disease in country districts.

The predisposing causes are various evil habits which break down the natural defenses of the body. Among these may be mentioned the habit of taking large quantities of liquids, especially cold liquids at meals. Nature seems to have anticipated the fact that the causes of diseases would be conveyed through the food and drink, and placed an efficient guard at the very beginning of the alimentary canal in the acid of the gastric juice. This acid in the normal stomach, and undiluted, is capable of destroying all ordinary pathogenic germs, even the Asiatic cholera vibrio. But, when the gastric juice is diluted with a large quantity of ice-cold water or other ice-cold liquid, the germicidal power is very greatly impaired, if not wholly destroyed. The use of tobacco and alcoholic beverages also predisposes to typhoid fever, as they produce a catarrhal condition of the gastric mucosa, thus greatly interfering with the natural germicidal action of the acid.

Prevention.—Having mentioned some of the causes, the first indication in the prevention of the disease is to avoid the causes. If we could secure a plentiful supply of pure water, and some satisfactory method of disposing of all kinds of excreta, the two chief factors in the causation of the disease would be disposed of.

Experience has proven that it is practically impossible to guard water-sheds closely enough to prevent pollution of the water. New York City is still attempting to accomplish this result in this manner. She will utterly fail. Some European cities have conveyed the sewage to farms where it fertilizes the soil and partly pays the expenses involved by the products from the soil. This method has given fair results, but not so good as the filtering plants which have been adopted by many cities. For rural districts the people should be taught to observe general hygienic regulations. An ancient rule required individuals to carry a paddle in the belt or girdle, with which they must bury excreta in the earth at a safe distance from a human habitation. This rule could be modified to meet the necessities of the twentieth century in rural districts by having a large sheet-iron pan under each seat in the closet, and a box or pail of dry earth, lime or ashes in the closet. With a shovel or tin cup the impurities could be thoroughly covered, and periodically removed and buried at a safe distance.

Barnyards should be so located that the impurities would not percolate through the soil and pollute the water in the well. This method would do away with a very prominent factor in the causation of the disease in the country.

Finally, every physician should be a philanthropist, and, by voice and pen, be a true teacher of hygiene. He should utilize the public press to publish articles which would educate the public upon this all-important subject. In no other

way will typhoid fever ever be stamped out.

Treatment.—The chief indications are to disinfect the alimentary canal and keep the temperature under control.

The first is accomplished both by drugs and diet. I prefer to clear the *prima via* by a saline cathartic in order that all debris may be removed. I follow this with five-grain doses of sulpho-carbolates of soda, lime and zinc, in such proportions as the individual cases require. The diet is *not sweet milk*, as is usually the case. As this is a departure from the almost universal custom, I will give my reasons for my position on the subject of diet: First, sweet milk is not a liquid food, but becomes a solid—sometimes a very tough, leathery solid—very soon after it reaches the stomach, hence it would be subject to all the objections of other solid foods. Second, sweet milk is an excellent medium in which to develop the typhoid fever bacillus, and as we do not wish to develop the typhoid fever bacillus, it is not wise to allow the patient to take sweet milk into his alimentary canal, since that would make an excellent culture tube for the growth of the "bugs." We must select a diet that will nourish the patient but discourage the growth of the germs. We find these requisites admirably fulfilled in fruit juices and fruit soups. Grape juice is especially adapted to both these ends.

The germs do not thrive in an acid medium, hence buttermilk might be used cautiously.

I *never give drug antipyretics.* I am confident that they do far more harm than good. They may lower the temperature, but they lower the blood-pressure also, and prevent the emunctories, the natural sewers of the body, from carrying the poisons out of the body as they should do. My chief antipyretic is hydrotherapy. On my first visit I pull off my coat and show the nurse how to give a sponge bath properly. Then I show her (or him) how to apply a compress to the trunk. This compress should consist of three or four thicknesses of cheese-cloth, and should cover the trunk from neck to thighs, and be covered with one or two thicknesses of flannel. A cold compress should be kept to the head also, and both changed as often as they get warm. They should not be wet enough to drip or wet the bedding. During the latter part of the night and early morning, when the temperature remits, the patient should not be disturbed, but allowed to sleep. In regard to the "tubbing," at a temperature of 70° F., for fifteen or twenty minutes, or until the patient is blue and teeth chattering, I will say that I am decidedly opposed to it. *There is a better way.*

When the temperature remains high in spite of the above treatment, place the patient in a full bath at a temperature but a few degrees below that of the patient. Allow a stream of cold water to enter the tub, while the patient is rubbed vigorously until the desired temperature is reached (70° or 80° F.). When the patient has been in this bath fifteen or twenty minutes, put him to bed, and allow him to sleep, with compresses to trunk and head.

Do not give whisky, but an abundance of wholesome, nourishing ice-cold grape juice.

In my worst cases I have placed the patient in a cold, wet sheet pack on a cot covered with a mattress, and a mackintosh, or rubber blanket. The patient enveloped in the wet sheet may be covered with a light woolen blanket, and at short intervals the blanket may be removed and the patient sprinkled with cold water without removing the sheet, and the blanket replaced. The head of the cot may be elevated an inch or two, and the excess of water caught in a pail or pan at the foot. After a little experience, the patient will scarcely awaken sufficiently to remark: "How good that cold spray feels!" and resume his sleep again. But the beauty of this method of treatment and diet is that the temperature will seldom rise above 102.5° F., and will be normal in from eight to fifteen days, while, according to other methods, he will be in bed from three to six weeks.

I have used the above method during the last ten years with great satisfaction to myself and my patients, and have never used alcohol (internally), nor coal-tar antipyretics, and during all that time I have not lost one patient from typhoid fever. If it appeals to you, try it.

Pneumonia and Its Different Methods of Treatment.

BY C. R. KING, M. D.,

Atlanta, Ga.

In confirmation of Dr. A. W. Riley's article (June, 1907,) on pneumonia and its different methods of treatment, and his experience with the virtue of quinine as a (or *the*) remedy in pneumonia, I will give your many readers a history of two cases in 1862, while acting as assistant surgeon in the cavalry service in the Confederate Army: One morning we had orders to march to another point. It was winter, was not cold at 12 M., and the boys worked very fast in loading up the wagons, and got very warm; in a short time a brisk norther blew up, chilling everything. Two of the men were stricken at once with *congestion of the lungs* (as some hair-splitting diagnosticians want to term it), which is nothing but pneumonia in its first (or congestive) stage. They came to me, white as sheets, almost cadaveric in features; not with fear, for they were not that sort; they could scarcely get their breath because of pain in the chest. I had no medicine except a few bottles of quinine.

My father had often told me (he being a physician) before the war that herculean doses of quinine would abort pneumonia. I sat on my horse and gave each man three doses of quinine—tablespoonful dose each, near as I could guess, and told them to go to the farmhouse nearby and go to bed, and take one dose every three hours, and on the third day they rejoined the command, saying to me: "Doctor, you cured us in one night—we came near splitting our heads open with the big doses of quinine, but it cured us in one night."

I would not now like to give three such doses in a few hours, as I did then, for I can get same results with smaller doses in same time.

I wrap my patients with cotton batting, after applying a good coat of two or three drachms of quinine, one ounce of mustard, and warm lard to mix to a thin paste. Cover cotton with bandage, and sew it on. I never use ice or mush poultice on my pneumonia patients. Nothing but the above, and that after giving a hot Epsom salts bath, or rub all over the surface of body and limbs. Never remove the cotton batting until patient is well. Then strip off a little of the cotton at a time, to prevent taking cold.

I give internally:

℞	Quinine	3	grains.
	Soda Salycil	2	grains.
	Piperine	1	grain.
	Strychnine Nit.	1/80	grain.

M. Sig: One capsule every two hours.

In connection with above, give:

℞	Fl. Ext. Lobelia	1	drop.
	Fl. Ext. Gelsemium	5	drops.
	Fl. Ext. Aconite	1	drop.
	Fl. Ext. Serpentaria	2	drops.
	Fl. Ext. Asclepias	8	drops.
	Fl. Ext. Belladonna	½	drop.
	Fl. Ext. Digitalis	½	drop.
	Ergotole	5	drops.
	Syr. Wild Cherry	½	drachm.
	Simp. Syrup, q. s.	1	ounce.

M. Sig: Given at same time or alternately. After each dose compel patient to drink a glass of water.

Also give freely about half-drachm each of bicarbonate potass. and bicarbonate soda, three times a day, in glass of water. Put patient in bed in warm room, where there is a kettle on the stove boiling oxygen into the air, from fresh water, changed often to furnish proper amount of oxygen, so doors will not have to be opened to provide fresh air, as such process would be deleterious, as I have seen the fresh, cold air act badly, especially in the army, in a few hours. Common sense, good judgment and truth from experience beats all unreasonable theories.

With above treatment my patients seldom need the third visit—often up the next day.

Uric Acid in the Blood.

BY E. M. GRIFFIN, M. D.,

Farmington, N. C.

Does the accumulation of uric acid in the blood cause it to be both thick and *black?* If not, what is the cause, and treatment?

[We hope our readers will reply, through the BRIEF, to this query, and detail this condition.—Ed.]

[Written for the MEDICAL BRIEF.]

Intravenous Therapy.

BY WM. F. BERNART, M. D.,
Chicago, Ill.

Drugs, as a rule, are administered in one of four ways, either by mouth, by inunction, by injection into the cellular or muscular tissues and by intravenous injections; the first two have been used from time immemorial, the third since modern times, and the fourth is practically of a recent venture. It is too frequently stated that because results can usually be obtained under the first two methods, that the latter two should be reserved for exceptional cases. It is often difficult to say when these unusual cases will arise, therefore every physician ought to be prepared and capable of resorting to the latter methods without a moment's hesitation.

The technique[1] of giving intravenous injections has been thoroughly handled by various authors, so I will confine my remarks to its therapy and results. Before going further into this subject, I wish to state that intravenous therapy, although of recent birth so far as its practical applicability is concerned, can by no means be considered as being still in its infancy, for the great amount of work done by the men who have adopted this method conclusively shows that it is well launched upon what promises for it a brilliant future. It is a method for the general practitioner as well as the specialist, for if the former will master its use he will have fewer cases requiring the assistance of the latter.

In severe cases of anemia from neurasthenia and other causes, Franck[2] demonstrated the value of intravenous injections of iron. In his series of cases, the beneficial results were not of a transient character, and the advantages gained by a course of this medication were not readily lost. For those cases which fail to assimilate the iron, when given by mouth or those in which the ferruginous preparations derange the stomach or produce diarrhea, the intravenous method can be considered as bordering on the ideal. Results under this form of medication can frequently be obtained at home and the patient need not suffer the financial hardships that are often imposed by a trip to the seashore, mountains, etc., at a time when he can least afford the expense.

In that prevalent disease, syphilis, how many thousands of afflicted people seek relief at some resort known because of possessing certain so-called special merits! These luetics are compelled, at a big expense, to frequent these places because the medicine given them at home had not been absorbed, and, therefore, had not found its way into the circulation.. There is probably no active syphilitic lesion but what will succumb to treatment, providing the treatment is accurately directed and unhampered by uncertainty. During the years in which I have used intravenous mercurial medication, I have been given every reason to believe that malignant syphilis is more or less of a misnomer. This method has never failed me in the production of desired results, and these results, as shown by a series of experiments[3], were accomplished in three-fourths the time required by intramuscular injections, less than one-half of the time taken by inunctions, and about one-fifth of the time required under oral administration. Similar results in the same specified time can be gained by any one at any place; special virtues and adjuvants are not necessary. Injurious complications in the wake of intravenous sublimate injections can be considered in the light of being a myth, for so far, a period of over fifteen years, during which thousands of injections have been given, no permanent harmful effects have ever been recorded. In a recent publication[4], I considered the so-called complications following the intravenous injections of mercury—reference is made to this to save the space a repetition would require. Iodine can also be given to advantage intravenously; this is apparent when an immediate saturation is essential, as in paralysis, when the drug is not tolerated by the stomach, or when unconsciousness prohibits oral administration. The intravenous administration of anti-syphilitic drugs is applicable to and of advantage in any stage or lesion of active syphilis. In syphilis of the nervous system, it

should entirely displace the slower and less uncertain methods.

Rheumatism is another disease which so rapidly and surely dissipates the time of the patient, and the salicylate preparations are the ones which so persistently derange the digestive functions. Mendel, the author of intravenous salicylate medication, speaks of it as being a specific for all recent rheumatic affections, and that it will often produce results after the ordinary internal and external salicylic medication failed. It reduces most promptly the exudate in the diseased joints. The advantage of this method of giving the salicylates can be plainly seen; it rarely requires over one injection a day, and does not produce a loss of appetite, sweating and ringing in the ears. Compare this to an energetic oral medication, where the patient must be given his medicine every few hours, both day and night, and where the treatment soon produces a deranged stomach, sweating, etc. A point of no little importance is, that in obscure cases a differential diagnosis can readily be made, as non-rheumatic disorders are not amenable to this plan of treatment.

Recently I tried the sodium salicylate intravenously as an abortifacient to a beginning attack of rheumatism, with the result that one five-grain injection eradicated all the symptoms. This case had previously gone through two very severe attacks of acute articular rheumatism, and felt that he was capable of judging the beginning of another attack. At the time the abortive injection was given, his right shoulder was involved to such an extent that it was nearly impossible for him to move the arm, the slightest motion causing excruciating pain. There was a moderate rise of temperature, and a beginning swelling around the joint. Within thirty-six hours after the injection all the symptoms had apparently disappeared. The attack so far has not recurred. Under this form of treatment, even after an attack has become thoroughly established, it rarely requires over eight or ten injections to bring about a cure.

The intravenous use of antiseptics has been given an extensive trial, with the production of some exceptionally good results. A preparation of soluble metallic silver has probably been the one most experimented with, and there is abundant literature to show its efficacy; it has, however, certain drawbacks which can not be readily overcome, these are the occasional production of severe chills and rise of temperature when this drug is used intravenously. Reports upon intravenous sublimate injections, so far as efficacy is concerned, are equal to those of silver, and, besides, the use of this salt is not followed by severe sequelæ; in fact, it has a marked antithermic action.

Antiseptics practical for intravenous use are indicated in severe cases of puerperal infection, septicemia, erysipelas, scarlet fever, typhoid fever, pneumonia, hemorrhagic diatheses, when due to bacterial origin, septic endocarditis, etc., but to be of value this treatment must be instituted before the patient's last chance for life has vanished. Mercuric chloride, especially, must be given in the largest doses possible, and frequently enough to keep up an intensive action. This method applied to this class of work is exceptionally fascinating, even though the exact alexiteric action of the drug used is not positively known. As the list of antiseptic drugs for intravenous use increases, it most likely will be possible to effect far better results than those obtained up to the present. Before leaving this part of the subject, I wish to state that this method is deserving of a trial in all refractory cases of the above-mentioned diseases.

Arsenic indicated in tuberculosis, diabetes, chronic skin diseases, chorea, neurasthenia, anemia, chlorosis, paludism, splenic leucocythemia, exophthalmic goitre, cancer (for its palliative action), Hodgkin's disease, etc., is another valuable drug that can be used intravenously. Occasionally the usual methods of administering this drug do not produce the desired results; it is in these cases that the intravenous route should be given a trial; then, if results are not obtained, it is useless to continue the arsenical treatment.

Intravenous injections have always been spoken of as a measure of last resort. In justice to this method of administering drugs I would suggest the displacement of this phrase by stating that

it is at present the highest therapeutical method. The former phrase is, in a certain sense, misleading, for it gives the impression that even if it does no good it probably will do no harm. This interpretation, which so many medical men have taken, is entirely erroneous, so the sooner it is eradicated the quicker will the intravenous method of administering medicines receive its just acknowledgment.

[Written for the MEDICAL BRIEF.]

Incipient Tuberculosis.

BY M. B. TULLER, M. D.,

Gibbs, Ky.

The importance of this subject is such that it requires the closest study by, and frequent discussion on the part of those who are interested in its suppression, though one almost palls with the reading on the subject, especially as the results of treatment are too doleful and monotonous to be encouraging. Nevertheless, it is our duty to persevere in our investigations and studies, trusting to the Giver of all good to reward our diligence with the means with which to stay the ravages of this plague.

In my opinion, tuberculosis is a disease of perverted or malnutrition, the predisposition to which may be either hereditary or acquired. While it does not necessarily follow that because a patient's parents or grandparents have died of tuberculosis that he will do so, it does follow that whatever weakens his powers of resistance will tend toward the development of tuberculosis in some form, either by infection or infiltration, as the case may be.

The writer knew one family of nine men and women whose mother died of tubercular consumption in her climacteric, every one of whom died of senile consumption upwards of seventy years of age, the third generation, upwards of fifty in number, dying of tubercular phthisis, between the ages of twenty and fifty. The following points, if any thing, may be inferred from this case:

1. That these people inherited the predisposition from the maternal family.

2. That by virtue of extraordinary vigor they resisted the encroachments of the disease until vitality was impaired by weight of years, when they succumbed to what was most natural to them.

3. That the progeny of these people, having a different environment, were not endowed with the same vigor of resistance and yielded to the invasion from early to middle life.

Those having an hereditary predisposition present one of two physical appearances:

1. They are tall, thin, rawboned, narrow and flat-chested, slim waists and stoop shouldered. They have thin skin, pale or slightly flushed complexion, or a complexion that flushes easily. The muscles appear long, slim, and are soft, never hard or firm, no matter what their employment may be. The hands and fingers are, likewise, long and slim. The hair is fine, silky, and the eyes are large, with an unnatural luster.

2. They may have broad shoulders and chests, but the chests are flat, and the subjects are disposed to take on adipose, even to excess, which, however, is never firm, but always soft and flabby. Every little illness causes rapid loss of flesh, which may be quickly restored after recovery, but never becomes firm. They have frequent "colds," often take them from very slight exposures, and are always liable to swollen glands, especially tonsils and lymphatics. Every scratch or cut of the skin may ulcerate or suppurate. The complexion may be florid, or dingy, unclean in appearance.

These are the two forms of hereditary tubercular predisposition, and are the types of cases taken from practice.

Both forms are prone to frequent gastro-intestinal disturbances, either simple

(atonic) or catarrhal indigestion, more frequently the latter. Certainly four-fifths of my pulmonary tuberculosis cases have been preceded for a greater or less period of time by an obstinate, frequently recurring, incurable passive gastritis. Indeed, this symptom has become almost pathognomonic to me, especially when the patient complains that every little cold he takes "seems to go to his stomach," or is accompanied by gastro-intestinal indigestion.

One of my cases, of the first described type, began his downward course with a violent attack of gastritis, from which he recovered, but was subject to frequent "bilious" attacks of greater or less severity for six years, when he developed tuberculosis, dying in about eight months after inception.

The presumption is that the impaired digestive function weakens powers of resistance, until the subject at least falls an easy prey to the infection. That the disease is communicable to those having such family predisposition has been apparently verified by my experience therewith.

The first symptom indicating a probable onset is persistent tachycardia.

The patient may, possibly, complain of nothing but a little weariness, but persistent increased pulse rate should, in proper cases, excite the suspicion of the physician what to expect.

The second symptom may be enlarged lymphatics. This is not a very frequent symptom, but may occur in connection with the more rapid pulse.

The third symptom may be noted by the patient as a shortness of breath upon moving more rapidly than usual, or upon ascending an elevation. The physician will find that respiration has increased by eight or ten to the minute. Auscultation now will possibly reveal nothing more than an inertia of the lung cells. There may be a slight indefinable roughness, but the cells do not fill well, the patient complaining that it requires too much exertion to breathe. The fourth symptom is the cough, a short hack, frequently repeated, or a hard, racking dry cough. The former is apt to be the beginning of chronic pulmonary tuberculosis, while the latter belongs to the more acute form, except when the larynx is the seat of the onset, when the cough may resemble, somewhat, that of croup.

The fifth symptom is more or less rapid loss of flesh, and continuous sense of lassitude. Prior to this time there may be no appreciable rise of temperature, not to exceed one-half to one degree in the evening. Now will begin a febrile action, remittent or even intermittent in character. In one case the temperature was subnormal every morning for several weeks, rising in the evening to 101° and 101.5° F. Percussion will now reveal dullness in the apices of the lungs, and auscultation will show prolonged expiration.

Continued hoarseness or huskiness of the voice may be the beginning symptom of tuberculosis pulmonalis. The pulse in such cases may not be accelerated until the apices of the lungs have been invaded. In one of my cases the hoarseness was a constant symptom for more than two years before there appeared any tachycardia, the patient dying three years later of chronic tuberculosis.

One case, age sixty-three, began with partial paralysis of hands and arms, and difficult locomotion and accelerated pulse, several months before the cough developed. She lived one year after the cough began. All of her family, with a possible single exception, died of some form of tuberculosis. All cases of ischiorectal abscess in persons of tubercular habit, or those subject to gastric catarrh or indigestion, should be regarded with suspicion, and the patient put upon such regimen and treatment as will support the vital powers. To this rule there may be two exceptions, viz., first, those which have developed from an attack of dysentery, and, second, those resulting from a contusion. Of this, however, I am not altogether sure, much depending upon the hereditary tendency of the patient.

Frequently recurring pleuritic stitches, with increased pulse rate, almost invariably indicate the development of tuberculosis.

Recurring attacks of colic, with loss of flesh and tachycardia, indicate a probable tubercular development. In one of my cases, a girl, seventeen years of age, several attacks occurred, with increasing severity, until in the last attack she ever had she took two grains of morphia sulph.

in less than two hours before the pain began to subside. She died sixteen months later of pulmonary consumption.

A second case, a young married woman, had repeated attacks of colic, and I warned her husband and parents that probably tubercular consumption was impending. This verdict displeased them and they sought other advice, which was not in accordance with my opinion. She died three months later of acute tuberculosis. Recurring attacks of colic, with loss of flesh and tachycardia, may be regarded with grave suspicion.

Suppressed or steadily failing menses should always be closely investigated. If accompanied by failing flesh, weariness, and increased pulse rate, tubercular invasion may be apprehended.

Prognosis.—Can incipient tuberculosis pulmonalis be cured? In the sense of deferring the disease an indefinite period, it is curable, but the prognosis should be both qualified and guarded.

In patients under fifteen years of age the prognosis is quite hopeful, except in the case of infants born of mothers well advanced in the second stage. Such children, in my practice, have all died in a few months. Between the ages of fifteen and thirty-five the prognosis is, as a rule, unfavorable. Between thirty-five and sixty, except in the case of women during the climacteric period, the prognosis, all things being equal, is fairly favorable. If, however, there be a luetic or alcoholic history, the prognosis is unfavorable. If the pulse becomes normal in frequency the patient will continue in good health until there is a recrudescence, some time in the future. If all the symptoms disappear, except the pulse rate, which continues at ninety or over, the case will be speedily fatal.

One of my cases, a young man, twenty-two years of age, apparently made a perfect recovery. Temperature and respiration became normal, cough disappeared, flesh was more than ever before in life, and strength, apparently, as good, but tachycardia remained. He asked me in August if he could not go to work sawing logs about the first of September. I advised him not to do so, as he could not afford to spend his strength at hard labor, with the winter ahead of him. He did not heed my advice and died the following December, having worked but three weeks in September in the forest.

The peculiar mental state of these patients makes it well-nigh impossible to impress them with the gravity of their cases, especially in the very early stage. If they are told plainly that they are in peril, they become angry and seek other advice, and, possibly, are deceived by the second adviser; and if he prescribe honestly, will neglect his treatment, because he has told them there is nothing serious ailing them. They will then seek the nostrums, and in a few months pass away.

Treatment.—"An ounce of prevention is worth a pound of cure." My advice to all people having a tubercular habit may be summed up in three words: Go to farming. Avoid the professions, the trades, the offices, the stores, warehouses, railroads; seek the soil and the air in a moderate, non-malarial climate, and, in my judgment, tuberculosis will soon begin to subside. True, farmers do die of tuberculosis, but my experience has been that a far smaller percentage of them die of that disease, and, other things being equal, it is more easily curable when contracted by them. Furthermore, a large proportion of the cases coming to my notice among farmers have been in advanced life, thus giving them a chance to do their measure of usefulness before leaving this world. In the mountains of this State and Virginia, so far as my observation goes, less than one per cent of deaths among the farming population occur from pulmonary tuberculosis. Changing climate, or rather getting away from the location where the disease was contracted, in incipient cases, has helped some of my cases to a much longer lease of life than they would probably have had.

But if they have recovered and persist in returning to their old home, a speedy recurrence and early death may be looked for.

Feeding should be milk, eggs, butter in large quantities, and raw beef, if the patient can be brought to eat it, and often predigested milk foods in quantities. Some cases under my observation have learned to eat raw, chopped, salted beef, to the extent of a pound daily, with evident benefit. In the beginning, the patient

should be encouraged to do light work, which will not tax his strength, preferably such as will keep him on horseback.

So far as internal medication is concerned, the three great remedies for incipient tuberculosis, in my experience, are salol and sulphur combined, calcium and bryonia alba.

The first of these prescriptions is antiseptic, antipyretic and alterative, and is more or less useful in all cases, even in conjunction with other treatment. I give it in nearly all cases, as a routine habit, until such time as I think it will accomplish no more. So far as the phenol enters into its composition, it is a modification of the creasote treatment. Its indications are so numerous that it can scarcely fail to be useful. Five grains of each, three times daily, will suit most cases, but if it appear desirable to increase the antiseptic dosage, five grains of sulph. and ten grains of salol may be safely and successfully given.

Calcium sulphide—systemic antiseptic—specifically indicated in those cases where the cough is alternately dry, hard and loose, and where the gastric condition craves mild acids. It may be given hourly until nausea is manifest, then less frequently, and often does excellent service.

Last, but not least, bryonia alba is specially indicated by three sets of symptoms:

1. By a more or less constant short, hacking cough, accompanied by frequent pleuritic stitches, which are especially aggravated on moving about.

2. By a hard, dry cough, accompanied by soreness of the chest walls, especially while coughing.

3. By a hard, dry, racking cough, which compels the patient to sit up in bed, and support the chest with the hands.

All the cases presenting either of these symptoms have been cured of the particular attack for which the drug was prescribed.

Calomel is a good second remedy, and is especially indicated in those cases having either a hard, racking, dry cough, or a short, hacking cough, with a furred or slimy tongue, and tenderness on deep pressure in the stomach. Calomel, one-tenth grain every two or three hours, will be very helpful in such cases, and materially assist them toward recovery. If the cough is hard and dry, without any of the symptoms indicating any of the above remedies, one sixty-seventh to one thirty-third grain of apomorphine, hourly, will be of great benefit, so far as that particular symptom is concerned, but having no especial systemic power will contribute nothing toward the recovery of the patient, except to relieve the cough. Such cases will be constitutionally helped by the syrup hypophos. comp.

Nitric acid is indicated by the following symptoms, viz., constant, dry, barking cough, from dark until midnight, with almost total relief after that hour.

Twice have I helped patients when this symptom was present. The first, a young man, age twenty-four, was cured for nearly a year, when a recrudescence occurred, and he ran rapidly down, dying in a little more than three months. The second, a woman, age thirty, was cured, ten years elapsing before there came a recrudescence, which was cured by bryonia tincture. In a third case, a young man, age twenty-six, the nitric acid did nothing, the patient dying in three months, of acute tuberculosis. Drop doses, United States Pharmacopeia dilute, repeated, as the patient will bear it.

In the hemorrhagic form, belladonna has been the most useful drug, so far as that particular symptom is concerned, and will greatly help the patient in a general way. Specifically, it is indicated by blood which feels hot to the patient, as it comes up, and which clots speedily upon exposure to the air. The blood may be dark red, or bright and profuse, but the hot sensation and the rapid clotting are always present.

If the patient is excited, and the pulse tense, the hemorrhage bright and frothy, aconite will speedily control it. If the hemorrhage is dark, and the patient pale and weak, the phosphate of iron will be useful.

One young woman, age twenty-two, contracted the disease while nursing a dying brother, was given iron phosphate up to ten grains daily, and made an excellent recovery.

All of these cases, however, need the syr. hypophos. comp. in varying dosage, and, after the specific indications have

been controlled, I never fail to prescribe the comp. The only case of acute pulmonary tuberculosis that I have ever seen recover, was from the use of this remedy in teaspoonful doses every two to four hours, day and night, until she was out of immediate danger, when it was reduced to three times daily. The patient was a tubercular subject, age twenty-six, and at the onset bade fair to compete with Da Costa's thirteen-day case. She was put at once upon the syr. hypophos. comp. every two hours, day and night, and the first forty-eight hours was given one two-hundredth of a grain of phosphorus on the alternate two hours, to aid in maintaining strength, and to combat the hoarseness. At the end of that time I discontinued the drug, continuing the comp. alone. The first sign of improvement was noted on the third day of treatment, when the temperature fell from 104° to 103° F. The disease slowly and steadily declined, until at the end of four weeks she was able to sit up in her bed, and soon thereafter got up. She died two years later, of a recrudescence. .

In my opinion there are three great constitutional predisposing causes of disease, and they are tubercle, uric acid, and syphilis, and their combinations. A diligent study of these diatheses, and the means necessary to keep them in a condition of ability to resist germ invasion, or to throw off the toxins carried by them, will greatly relieve the world of its germiphobia, the main office of the microbe being, in my opinion, that of purveyor of toxins or virus. The sunshine may possibly destroy the activity of certain germs, particularly the bacillus tuberculosis, but it will never destroy the virus of advanced cases, as carried by the bacilli, even though the amount be infinitesimal. Hence, in all cases of tuberculosis I instruct the family to have the sputa burned, and the dejecta I order buried in the soil, not near a water course.

When this instruction is obeyed, I rarely have a case of infection resulting from my consumption cases.

I leave the discussion of the other stages of this disease to those whose experience may not have been as distressingly monotonous as mine. Suffice it to say, that I advise my patients that they need but little medicine, just sufficient to relieve whatever distressing condition that may arise, to take all the sunshine and good food that they can, and, particularly, not to take nostrums, which latter injunction they at once proceed to disobey.

[Written for the MEDICAL BRIEF.]

A Brief Resume of the Musculature and Fascia of the Pelvic Exit.

BY BYRON ROBINSON, B. S., M. D.,
Chicago, Ill.

I. MUSCLES OF THE PELVIC EXIT.

In the pelvic floor or pelvic exit there is compromised a series of muscles with similar position and function. The muscles of the pelvic exit may be divided into two groups, viz., (1) those of the pelvic floor; (2) those of the perineum. The musculature of the proximal series of muscles in the pelvic floor forms the funnel-shaped muscle plate and produces the diaphragma pelvis rectale. It is the chief muscular layer of the pelvic floor. It presents ventralward a slit for the genito-urinary organs (vagina and urethra) and dorsalward a slit for tractus intestinalis (the rectum). The musculature of the distal series of muscles are closely associated with the rectal and genital sphincters. In general observation of the muscles of the pelvic exit indicates that they are associated with the distal ends of the rectum and genito-urinary apparatus and also that they render common function to these apparatus. The following scheme will present the muscle groups of the pelvic exit:

Diaphragma Pelvis.	Diaphragma pelvis rectale. (Diaphragma pelvis proprium.) Diaphragma pelvis uro-genitale. (Diaphragma pelvis accessorium.)

Diaphragma pelvis rectale arises from the ventral and lateral pelvic wall of the lesser pelvis and becomes inserted into its opposite fellow in the median line. According to some writers each half of the diaphragma pelvis rectale is composed of four muscles (coccygeus, ischiococcygeus, pubo-coccygeus, pubo-rectalis). Others call the composite half the coccygeus and levator ani which is convenient from practical purposes.

Diaphragma pelvis uro-genitale is a trapezoid formed muscle plate located in the angulus pubicus. In women it ensheaths or surrounds two canals—vagina and urethra, which penetrate it. The urogenital diaphragm consists of three muscles, viz.: (1) *Musculus ischio-pubicus.* This muscle located in the subpubic angle may be present in limited quantity, but its tendons are present on both sides representing the ligament arcuatum pubis and ligamentum transversum pelvis. (2) *Musculus transversus perinei* profundus which arises from the rames pubis and ramus ischium, and passing dorsal to the vagina terminates in the cetrum tendineum. (3) *Musculus urethro-vaginalis* which arises from the membrana intercruralis, ligamentum transversum pelvis and from the walls of the plexus pubicus impar. The pelvic floor muscles serves two purposes, viz.: (1) Aid to support the pelvic viscera. (2) They act as sphincters to the distal end of the tractus intestinalis (diaphragma pelvis rectale) also as sphincter to the distal ends of the tractus genitalis and tractus urinarius (diaphragma pelvis, uro-genitale).

II. FASCIA OF THE PELVIC EXIT.

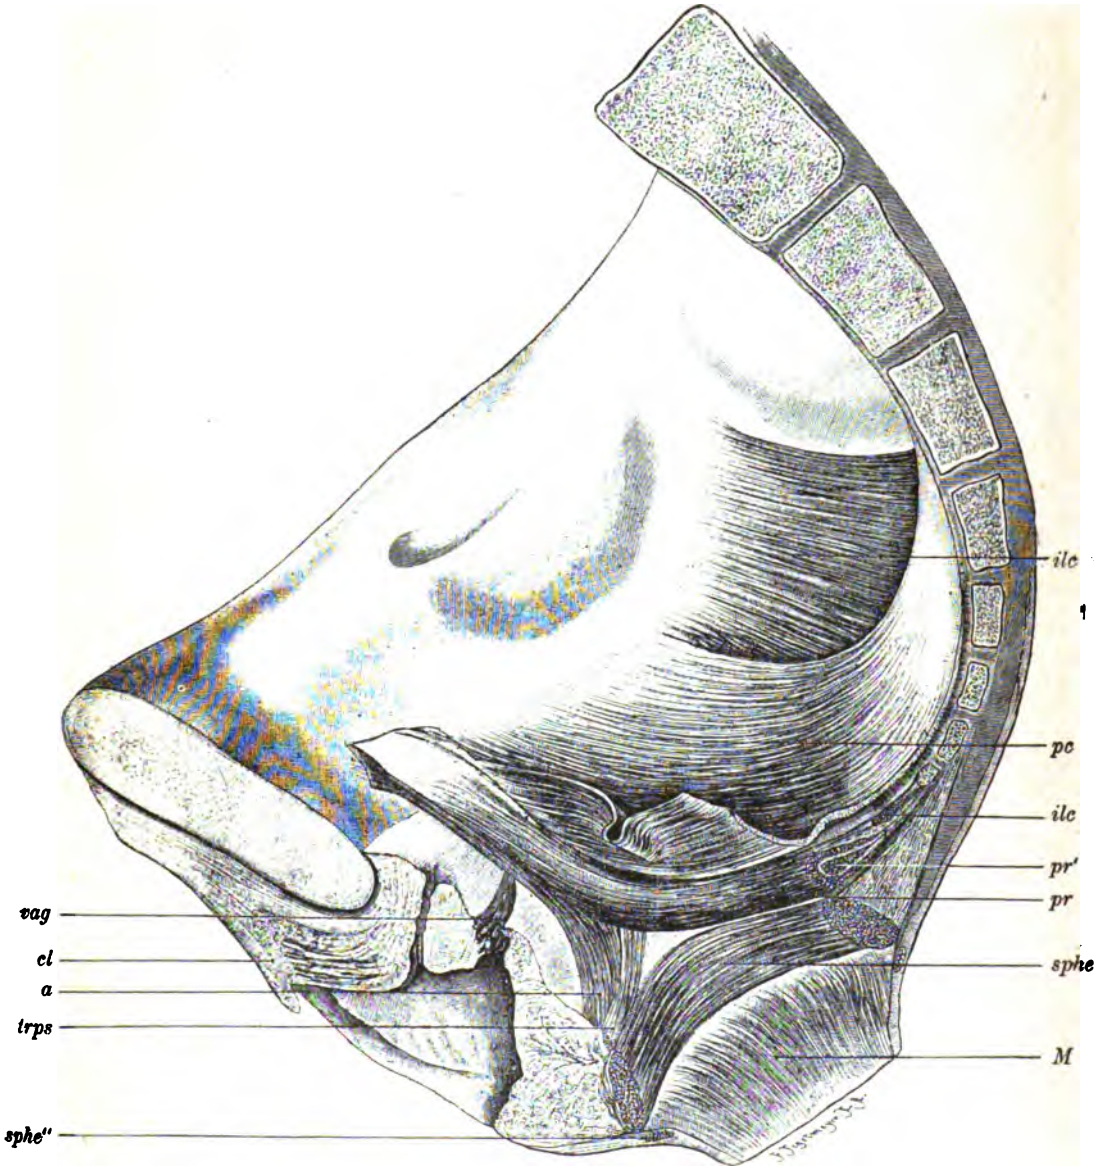
The fascia of the pelvic exit must be considered as belonging to the muscles which it ensheaths. In order and form the fascia compounds and belongs to the muscles. The pelvic fascia serves several purposes, viz.: It acts as a fixation apparatus for the pelvic viscera. (2) it forms the chief support for the pelvic viscera (the muscles aid in functionating the viscera and to a moderate extent in support). (3) The pelvic fascia maintains in ordered planes the muscles of the pelvic exit. Fascia may be a simple, fibrous, shiny, tendineous membrane or loose connective tissue. The development of fascia depends on its function on its environments. Professor Holl, of Gratz, Germany, divides the pelvic fascia into three classes, viz.: (1) fascia subcutaneous superficial; (2) fascia ensheathing muscle; (3) fascia pelvis internal (visceralis).

(1) *Fascia subcutanei superficialis* is located in the regioano-perinealis. It is a continuation of the gluteal fascia and lies between the skin and muscle fascia. It lies on the perineal body between the skin and muscles and adjacent to the anal region.

(2) *Musculus fascialis* ensheaths the muscle and maintains the muscles in functionating order. Each muscle (*e. g.*, obturator internus, levator ani, coccygeus) is ensheath from origin to insertion with a distinct fascia of one or more cleavable planes of fascia. Where adjacent muscles lie in contact the ensheathing muscular fascia may coalesce, blend and present intra-muscular fascial septa. The diaphragma pelvis (composed of the levator ani muscle and covered directly or the levator ani fascia proximal and distal) presents the most typical apparatus of a combination of fascia and muscle. The functions of the levator ani muscle are governed, controlled, by an ensheathing fascia and practically its utility depends on its fascial relations. The fascial relations also enhance strength for its contraction force can be localized for effective purposes by its extensive proximal and distal surface fascial relations, *e. g.*, it resembles the circulation of the tractus genitalis (intestinalis, urinarius, etc.) which can be concentrated by irritation gestating ovum, neoplasm enticing the chief blood stream to a definitive area, so by contraction of the levator ani and the arrangement of the proximal and distal fascia may be localized, concentrated in single localities as contraction of vagina, rectum, urethra. The diaphraghma pelvis (levator ani muscle with its proximal and distal fascia) is one of the most significant musculo-fascial apparatus known) the diaphragma thoracic a precisely similar apparatus. The levator ani fascia proximal and levator ani fascia distal has coalesced blended into two distinct fascial blades (proximal and distal) which emit numerous intermuscular fascial septa between the loose parallel levator ani bundles.

(3) *Internal pelvic fascia the fascia visceralis or pubo-sacralis.* This fascia consists of single or multiple cleavable planes of connective tissue which fix the pelvic viscera in order for functionation and support. The chief origin of the pelvic visceral fascia appears to be the arcus tendineus or white line.

We may view the pelvic visceral fascia, fixing the organs as projecting, cleaved planes of the levator ani fascia proximal. vis lining its wall an aponeurosis for its muscles. The pelvic fascia is attached firmly to the pelvic brim at its entrance



SAGITAL MEDIAN SECTION OF FEMALE PELVIS HARDENED.

FIG. 14. The preparation has been accomplished in the internal pelvis. It presents especially the course of the muscularis sphincter recti or musculus pubo-rectalis (ilc) and (ilc) a broad musculus coccygeus (pc), musculus pubo-coccygeus whose ventral segment is reflected in order to obse rve the musculus pubo-rectalis or sphincter recti, a, a bundle of the levator ani muscle (pubo-rectalis) coursing to the centrum tendineum as well as to the musculus sphincter ani externus and musculus transversus perinei superficialis (trps), transversus perinei superficialis. The musculus pubo rectalis (levator ani) consists of two layers, where by the one (pr) is groove formed. the other (pr') represents a thick bundle lying in the groove of (pr) (after Holl).

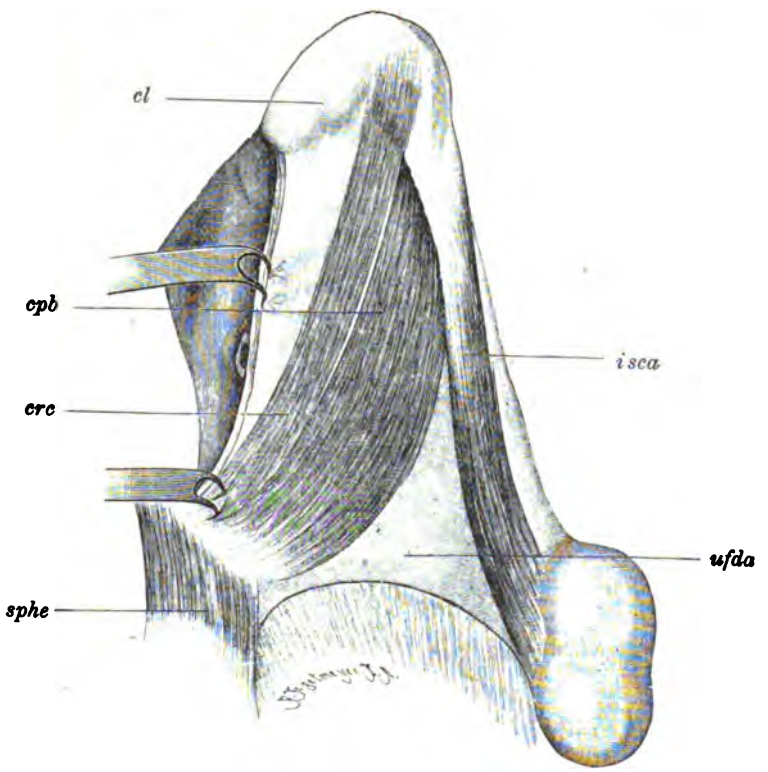
The pelvic fascia lines the internal pelvis from proximal entrance to distal exit it presents the cylindrical form of the pel- (*i. e.*, at the sacral promontory, ileopectineal line and dorsal surface of the pubis). It is attached at the pelvic exit to the

coccyx, major sacrosciatic ligament, tuber-ischii and to the base of the triangular ligament. This fibrous cylindrical membrane should be known as the *parietal pelvic fascia.* Individually it includes the fascia pyriformis, fascia obturator and fascia triangulare dorsalis. It becomes firmly inserted into the bones projecting into the pelvic exit, viz., ischial spine, symphysis pubis dorsalis, coccyx. The white line or arcus tendineus, a thickened band of fascia, extending from ischial spine to the dorsal surface of pubis practically represents the division between the pelvic cavity and iliorectal fossa. The white line presents two important factors, viz: (1) It is the origin of the levator ani muscle. (2) It serves as the origin of the significant levator ani fascia proximal (recto-vesical or visceral pelvic fascia) and levator ani fascia distal *this is the distal pelvic fascia.* The levator ani fascia proximal divisible in to many cleavable planes blends with the muscular walls of the rectum, vagina and bladder.

APPLICATION OF STRUCTURE AND FUNCTION TO METHODS OF TECHNIQUE.

Having examined the structure of the pelvis in detail (muscularis and fascia) me may now combine the anatomic factors which explain successful colpoperineorrhaphy. The first is the restoration of damaged fascia. A second important factor is deep suturing. A third element in a successful operation is the restoration of function by means of restored muscular relations. A fourth is the forcing in the median line of adjacent perineal tissue, and a fifth factor is the flap method of operation whereby there is no denudation or loss of tissue; and the flaps (skin and mucosa) avoid infection and insure primary healing. The flap method enables the operator to dissect to the lacerated structure or to reach the seat of the lesion, either by cleaving, splitting tissue or deep suturing with a handled needle with an eye in the end. Silk worm gut which is used in suturing, being nonseptic, may remain for weeks in position, like a splint, before removing. Among the fasicæ of importance are: The levator ani proximal and distal, the triangular ligament and deep layer of the superfiscial fascia, and the ischioperineal ligament. The operation of colpoperineorrhaphy is the result of evolutionary processes of failures and successes. In the beginning it was considered sufficient to unite the superficial or external tissues at the site of the lesion. This experiment soon demonstrated its own failure, and later it was deemed essential to restore the deranged and lacerated muscular elements in the pelvic floor. The attempt at successful colpoperineorrhaphy by reuniting external tissue at the site of the lesion, or restoring deranged or lacerated muscles to normal relations proved a failure to such a degree that it was evident that some other factor played a role; this factor was the *fascia.* The restoration of the lacerated tissue at the site of the wound, with the deranged and ruptured muscles, and the restoration of the deranged fascia are the three factors on which successful colpoperineorrhaphy rests. To Dr. T. A. Emmet must be given the credit of the view that the pelvic fascia played an important role in successful colpoperineorrhaphy. Experimental labors on the perineum, in a desultory manner, have been conducted for fifty years. But only lately have experimental and anatomic data been judiciously combined so as to render clear what are the useful methods in colpoperineorrhaphy. All successful surgical procedures demand an anatomic basis so that physiology may be restored. The deranged and lacerated parts in colpoperineorrhaphy must be restored in a manner simliar to that in operation for hernia. The successful surgical procedures in colpoperineorrhaphy have passed through the same evolutionary process as have the various operations for hernia. In hernia we must restore the anatomic relations, the obliquity of the inguinal canal, so that its valve-like action makes it impossible for the viscera to again protrude. In colpoperineorrhaphy, not only the anatomic parts should be restored, but the various canals and exits must also be restored to ensure permanent physiologic success. Deep suturing, so essential, is only groping after an anatomic base to restore the ground work. The same ideas are involved in the views of discerning surgeons who suggest that

if the sutures include sufficient of the rectovaginal septum, or if they are introduced deep sufficiently to make ventralward traction or if they include the sulcus on either side of the projecting vaginal wall, the operation will be successful. Dr. W. R. Wilson wrote a brief but comprehensive article on the subject, suggesting excellent principles, but modestly claiming that the anatomic basis is still imperfectly understood. In the subject of colpoperineorrhaphy the origin of the evitable lesion of the deep perineal fascia. This will destroy the tone of the dorsal vaginal wall because the fascia has been separated from the vaginal wall adjacent to its exit. If the distinct ischioperineal (ligament) fascia be torn, which is quite frequent in parturition, the pudendal end of the vagina falls dorsalward and begins its condition of rectocede; its fascial (and doubtless muscular) supports have been torn. With a torn levator ani fascia proximal the pelvic viscera will inevita-



MUSCLES OF THE CLITORIS BULBÆ VESTIBULÆ.

FIG. 15. (cl), clitoris; (cpb), musculus compressor bulbi proprius; (crc), musculus constrictor radicis clitoridis; (isca), musculus ischio-cavernosus; (sphe), musculus sphincter ani externus; (ufda) distal fascia of diaphragma uro-genitale (after Holl).

lesion demanding operation should be studied. The cause of the lesion, requiring repair, is almost always the result of the first parturition, more rarely other forces produce sacropubic hernia. The lesions of the perineum may arise from the ventral movement of the head lacerating the levator ani fascia proximal and distal with damage to the ischioperineal (ligament) fascia and tearing of the triangular ligament, with consequent inbly move distalward, for it is unphysiologic for a muscle to act as a continuous, tensionized support for viscera. But it must be remembered that the fascial layers of the pelvis are not only of value as visceral supports by separate and distinct connection in themselves, but they are of significant importance as serving a means of visceral support and for a point of attachment for muscles lying between their blades. The levator ani, which is

the most important muscular apparatus on the pelvic floor, serves by its fascial attachments as a visceral support to the rectal and vaginal walls as well as to the pelvic floor, for the uterus is supported practically by the intact pelvic floor.

The pelvic floor may be considered as composed of two widely superimposed, overlapping valves (D. Berry Hart). Whatever disturbs the relations of these valves tends toward -sacropubic hernia. The ventral pelvic valve is composed of the bladder, urethra, ventral vaginal wall and retropubic fat. The dorsal pelvic valve is composed of the vaginal wall, perineum and rectal wall. The pubic segment is attached to the symphysis pubis and composed of loose connective tissue. The retropubic fat is loose and spongy, the peritoneum may be easily stripped from the bladder and the bladder from the vagina. In labor, this segment becomes elevated and is the one which easily becomes deranged or acquires pathologic conditions, and especially is liable to prolapse or sacropubic hernia. The levator ani fascia proximal becomes torn from the walls of the bladder and vagina, allowing the intra-abdominal pressure to force the bladder and vagina distalward. When the uterus prolapses (sacropubic hernia) the ventral vagina wall appears at the pudendum first. The strong levator ani fascia has been torn from its walls and when the same fascia has been extensively torn from the bladder it prolapses also. In vesical prolapse the peritoneum with its many cleavable planes of subperitoneal (fascia) tissue becomes torn from the bladder. The sacral valve of the pelvic floor, consisting of the dorsal vaginal wall, the perineum and rectum is attached by strong fascial connections interwoven by muscles to the coccyx and sacrum. In parturition this segment is forced dorsalward and straightened extended. It becomes defective by laceration at the perineal body, the vagina loses its normal curve and sacropubic hernia is initiated, *i. e.*, retroversion begins, which is the inevitable factor in sacropubic hernia. The uterus itself has nothing to do with prolapse, it is inert. Intra-abdominal pressure and effective sacral and pubic segments account for prolapse; the sacral segment is fixed; the pubic segment is movable.

The functions required of the pelvic floor are to resist intro-abdominal pressure and to permit rectal and vesical functions. The structural anatomy of the pelvic floor must not only be studied in general as to its segments, valves, muscles and fascia, but each individual organ should be studied as regards its supports. The uterus has its individual supports, which though not separate from the fascia and muscles, should be well considered, for colpoperineorrhaphy may be required for (prolapse) sacropubic hernia without visible lacerations. The first elemental individual supports of the uterus are the uterorectal (sacral) ligaments. They consist of two folds of peritoneum embracing muscular and strong connective tissue extending from the dorsal surface of the cervix to the rectum (perhaps some fibers do extend to the sacral fascia). These ligaments are an extension of the muscular and connective tissue fibers of the promixal end of the vagina backward. As Dr. Frank Foster notes, the vagina and uterorectal ligaments form a balance beam on which the uterus rests. Yet it should be borne in mind that organs do not rest merely on bases, but are swung on supports or mesenteries. The brain, liver, heart and uterus are all suspended by supports and do not rest merely on other organs or bases. The uterorectal ligaments are powerful, peritoneal, muscular and connective bands which vigorously suspend the uterus by the neck which is blended in the pelvic floor. Careful dissections and vaginal hysterectomy will demonstrate that the uterus could not descend without the uterorectal ligaments became elongated. The uterus is supported by innumerable threads which extend from the pelvic wall to it. The so-called uterine ligaments are supports only in pathologic status. The uterus is said to be suspended by so-called ligaments (round, broad, sacro-uterine) fixed by intra-abdominal pressure; or supported by the pelvic floor.

(To be continued.)

[Written for the MEDICAL BRIEF.]

Syphilis.

BY J. DABNEY PALMER, M. A., M. D.,
Monticello, Florida.

Syphilis is a specific, contagious, chronic disease, communicable by inoculation, by contact of surfaces, by hereditary transmission, and, most commonly, by impure sexual connection. As early as 1380 John Gadisses gave ample proof of its contagious nature. About the year 1500 Benedict Victorius advanced the curious opinion that it was "epidemic, and originated from an unwholesome disposition of the air, and a spontaneous corruption of the humors, contracted by an error in diet, or the abuse of the nonnaturals." He wrote an elaborate essay going to prove that "the putrid humors are sufficient to produce it," and to put the matter beyond all doubt, he testified that he happened to know "some very worthy and religious nuns who were confined in the strictest manner, unfortunately contract the disease from the peculiar state of the air, together with that of the putrid humors and the weakness of their habit of body." This doctrine, though at the present day we smile at its absurdity, was really not only believed, but stoutly defended by physicians.

The question of the origin of syphilis has given rise to much fruitless discussion. It has existed ever since prostitution prevailed in the world; and this has been from the remotest antiquity and among all nations. Descriptions of it are found in the earliest writings, and traces of it are discovered in the bones of prehistoric people. Chinese accounts of it date back to the writings of Hoan Te, who lived about 2637 B. C. And the Japanese historians described it several thousand years ago. The Hebrews were familiar with it, and it is probable that many cases called leprosy were really syphilis. Hippocrates and his successors describe it as it existed among the ancient Greeks, and Celsus speaks of it among the Romans. It is found all over the world, and in its frequency and virulence is not modified by climatic or geographical conditions; but it is worthy to note that the disease is unknown among savage peoples who have not come in contact with civilized communities. There is no disease so widespread in its dissemination, nor so potent in its influence upon the human species, and none so characterized in the different stages of its progress by a greater number of pathological changes in the tissues of the body. The negro race is believed to be more susceptible to it, and to have it in a severer form than the Caucasian. This may be explainable on the ground that the disease is a comparatively new one to that race, which has not had time to acquire immunity.

Syphilis belongs to what Dr. Farr calls the enthetic order of zymotic diseases, which have the property of being developed in the system after the introduction of a specific poison, and originates in morbid secretions, in conjunction with the disgusting want of cleanliness about the genital organs so common among a large portion of human beings. The term is derived from the Greek *σιφλος*, filthy; and aptly indicates its origin. It is peculiar to the human species, and is always due to contact with a syphilitic individual or with his secretions or discharges, and produces no effect whatever on any of the lower animals, with the possible exception of the monkey. It can not be conveyed in the form of vapor, or, in other words, by breathing air which is contaminated by a syphilitic person. It is necessary that the poison should be applied to some part which is soft or covered with a mucous membrane, or else to some place where there exists either an excoriation, ulcer or wound.

The investigations of Schaudinn show that the disease is caused by the microorganism *spirochæta pallida*, a serpentine and flexile organism, resembling a corkscrew, having sinuous movements like the swimming of a snake or an eel, and found only in primary and secondary syphilitic lesions. It has no delicate, wavy filaments, called flagella, for locomotion, like other bacilli. Its size is about the one-twenty-five-thousandth of an inch. It was at one time believed by the greater number of the medical profession that syphilis and gonorrhea were

caused by the same poison, and that a neglected case of gonorrhea would terminate in syphilis. At the present time, however, all practitioners regard them as essentially distinct, and due to poisons altogether different in their nature. A simple and sure test for determining their difference is by inoculation, which has been brought into great repute by Ricord. If the pus of gonorrhea is inoculated into the skin of a healthy person it will never produce a chancre; while if the pus of a chancre, or any secretion of a syphilitic person, be inoculated, it will invariably produce another chancre. The saliva of such a person contains the specific poison, and in this way inoculation may occur by kissing, and by the use of pipes, spoons, cups, pencils, sticks of candy, plugs of tobacco, etc.; the blood also is capable of spreading the disease by inoculation. The comparison of the coccus of gonorrhea with the organism of syphilis also demonstrates their difference. All authorities now accept the *gonococcus* as the specific cause of gonorrhea. It was first observed in the urethral and conjunctival secretions of gonorrhea, and purulent ophthalmia by Neisser in 1879, and is described as a minute vegetable parasitic, pathogenic organism, biscuit-shaped, non-motile, non-flagellate, and without spores. The immunity to syphilis given to persons who have had it, and to healthy mothers who have borne a syphilitic infant, is another distinguishing feature of the disease. The syphilitic poison operates progressively from the first moment of its application, although it may not be perceived by a careless person till later. In a few days or weeks after infectious exposure a disagreeable itching calls attention to the genital organs, and upon examination, a small pimple, not larger than a pin's head, is observed, or a slight abrasion or fissure assumes an unhealthy appearance. These soon heal over, leaving no visible signs of danger. This is the period of incubation, and lasts from two to six or eight weeks. At the end of this period a hard thickening is felt at the site of inoculation, which soon breaks down into a small excavated ulcer, as if it had been scratched off with the finger-nail. This ulcer is situated on a hard base, and is known as the hard chancre. There is no inflammatory areola, but the edges terminate abruptly, and are elevated, making a deep excavation, like the hole of a shoe-punch. If a patient presents himself with an ulcer thus characterized, within five days from its first appearance, the disease admits of being checked at once, without the necessity of a particle of medicine. The proper method is to excise it with scissors. This is done in an instant by means of a small forceps, so constructed as to grasp the base of the ulcer, then raising it up, a single clip of the curved scissors removes it at once, and with it all apprehension may vanish. Instead of this, some surgeons prefer the application of strong nitric acid, an application which will very commonly suffice to annihilate the specific character of the ulcer. But neither of the foregoing plans can be adopted with safety, if the chancre is inflamed, the patient feverish, or if there is any local swelling or tenderness in the groin. When this is the case, black-wash or iodoform should be applied. The local swelling and tenderness in the groin indicate the formation of a bubo, from absorption of the poisonous secretions of the chancre, and the ordinary time of its appearance is just as the ulcerative stage of the chancre is ceasing. Women rarely suffer from bubo. The best treatment is the daily application of the following ointment:

℞ Ext. Belladonnæ.....1 drachm.
Unguent. Hydrargyri.....1 ounce.
M. ft. unguentum.

As soon as pus has formed, it should be evacuated by a free incision, followed by soothing dressings.

A characteristic set of symptoms now appears. A rash, somewhat resembling that of measles, breaks out upon the chest and abdomen, spreading thence to the face, extremities and back. The rash marks the secondary stage of syphilis, and is attended with constitutional disturbances. There is slight fever, with severe nocturnal headache, pains in the bones, and general indisposition. The tonsils, soft palate and lymphatic tissues of the pharynx become swollen, and, together with the gums, tongue and inner side of the cheeks, are the seat of mu-

cous patches. These are small, grayish or whitish papules, or shallow ulcers which discharge a most infectious secretion. Mucous patches also appear on the inner surface of the nose, the eyelids, about the genitals and arms. The throat is sometimes so sore and painful that eating solid food becomes impossible. Coincident with these changes in the skin and mucous membranes, several other tissues are affected. The periosteum covering the tibia, skull, clavicles, or sternum becomes the seat of inflammatory thickenings, or nodules, tender to the touch. The joints swell. The hair may come off in considerable quantities. The lymphatic glands continue swollen. A small gland just above the inside of the elbow—the epitrochlear—is almost invariably affected in syphilis, and rarely in other diseases, and is, therefore, a valuable aid in the diagnosis of doubtful cases. Syphilitic iritis is apt to occur during this stage. The period of the active manifestations of syphilis, embracing the primary and secondary stages, extends over a year, after which the tertiary stage sets in. The characteristic lesion of this stage is the gummata, which consists of soft, elastic tumors, and may develop in any situation—skin, bones, liver, testes, kidneys, lungs or brain—and vary in size from a hemp seed to a walnut. They are very prone to break down and ulcerate, often resulting in great loss of tissue and hideous scars and deformities. The bony framework of the nose is frequently destroyed. Several disorders of the nervous system, like localized paralysis and convulsions, are due to gummata on the surface of the brain or the roots of the nerves. There is certainly not a more pitiable object to be seen than a man, young, or in the prime of life, suffering from the last stages of this dreadful disease; covered by rupial sores, the lip dropped and saliva dribbling, defective in his articulation, insecure in his walk, dragging one leg behind him, and the victim of the most frightful epileptic paroxyms.

"In the treatment of constitutional syphilis," Dr. Erichsen says: "Our object is not so much to relieve or to remove any local morbid condition, as to eradicate the poison from the system, and, indeed, the various local manifestations, more especially those that appear on the cutaneous and mucous surfaces, may possibly be efforts of nature for the elimination of the virus from the system through the medium of the great excretory and emunctory organs, and it is often apparently by aiding this natural action by the administration of those remedies that act upon the tissues, that the poison is most effectually eradicated." According to these principles the essential remedy is some preparation of mercury, the obvious effect of which is an increased activity in the secreting and exhaling apparatus. Of its value in constitutional syphilis there is abundant proof; but undue preference is shown to some preparations to the exclusion of others; for instance, calomel is too often employed and corrosive sublimate is too much neglected. In these cases reliance may be placed in the following prescription:

℞ Hydrargyri Chlorid. Corrosiv.....4 grains.
Acid Nitro-Hydrochlor.....1 drachm.
Tinct. Cinchonæ Comp.....ad....6 ounces.

M. ft. sol. Dose: One teaspoonful in water three times a day, after meals.

Among other remedies deserving special notice is sodium iodide, which has been used with remarkable success in Italy. It should be given as follows:

℞ Sodium Iodide.....1 ounce.
Tinct. Stillingia.....4 ounces.
Tinct. Sassafras.....4 ounces.
Tinct. Xanthoxylum.....2 ounces.

M. ft. sol. Dose: One tablespoonful in half tumbler of water three times a day, after meals.

These will usually suffice to eradicate the disease.

Free Clinic.

On September 24, 25 and 26 Dr. E. H. Pratt, of Chicago, will hold a free clinic in orificial and general surgery at the Hering Medical College, corner Wood and York streets, Chicago. Tuition and operations free. Doctors invited to bring cases. All schools welcome. For particulars address Dr. E. H. Pratt, 100 State street, suite 1202, Chicago, Ill.

[Written for the MEDICAL BRIEF.]

Congestion of the Portal Circulation.

BY LINTON D. LANDRUM, M. D.,
Columbus, Miss.

Congestion of the portal circulation is called by various names, according to the complications it excites—sometimes being denominated yellow chill, also congestive chill, hematuria, congestion of the liver. But these all arise from this one primary cause.

This disease is peculiar to the South. But why it is that so-called malaria should affect so seriously the liver, but no other organ, we do not know any more than we know why the Southern sun should paint the iris a beautiful brown and the hair a glossy black.*

Congestion of the liver is always accompanied by fever, and the fever is in ratio with the intensity of the congestion, and its intensity adds much to the peril of the patient.

This disease frequently does not manifest itself until the subject of the malady has passed *in extremis*.

In such cases the portal congestion has become so violent that the man, engaged, perhaps, in his ordinary occcupation, falls unconscious, and is thus borne to his home. By the time the physician reaches him his skin has assumed that characteristic appearance denominated "goose skin," thus indicating that the blood has deserted the superficial circulation, and is moving only in its deep courses. This is owing to the nervous shock by which the nerve supply from the brain to these smaller vessels is cut off, further indicated by the coma in which the patient lies. Now is the time when something must be done—done effectually and at once—for already the patient's cheeks brush the dews of the river of death, and the crossing can not be far away. It is in cases of this kind that calomel comes to the patient as a messenger of life, arousing the dormant secretions, opening the flood gates, and turning back the deadly trend.

In one case the physician reached the patient about eleven o'clock A. M., found him in the condition above described. The physician at once administered to the patient thirty grains of calomel, and left, remarking to the overseer on the plantation that the negro man would likely recover if he lived long enough for the medicine to act. As to that, replied the overseer, if that negro was the only cause you had of returning here, I would advise you not to come, for he will certainly be dead before the setting of the sun.

On visiting the plantation the next morning there were several others sick, and going into this negro's cabin, the physician found his patient sitting up on the side of the bed and asking for soup. Full doses of quinine were prescribed for the two following days, when the patient was discharged.

There are some cases in which the collapse is so profound that there is not sufficient bodily power—vital power—to sustain the action of the calomel. Thus the physician found the patient, a lady, in a state of collapse, but her mind was perfectly clear—differing in this respect from the case above described. But, though her mind was unclouded, she had no realization of her extreme peril. On being asked how she felt, she replied: Oh, I feel pretty well, Doctor. I think, with your assistance, I will be up and about in a day or so. In less than two hours from that time she was dead.

In another case the patient was taken with a chill on Saturday. Not much was thought of this. On Sunday he had a second chill with high fever. Physicians were sent for—two of them. These physicians seemed to have given the patient everything they could think of except the right thing. Another physician was called in about seven o'clock Monday morning. This physician found the patient with something like black vomit—that is, he was vomiting profusely dark, bilious vomit, and sinking rapidly. It was too late for medicine to have time to act, and he only suggested that the patient be allowed to die in peace. By ten o'clock he was dead. Here a fine young man, the idol of his parents, died, whose life

* Only the negro has the "jet black eye," or those that have negro blood in their veins, as the white mulatto. Though the white man's eye may look black, if you turn the light on it you will discover that the eye is a beautiful brown.

might have been saved by unlocking his liver with a large dose of quinine, followed by quinine in similar proportion.

In cases of this character delays are dangerous. You must do what you are going to do at once. Calomel is your sheet anchor; there is nothing that will take its place.

I will mention only one more case of this character: This was a young negro man about twenty-nine or thirty years of age. This man fell in the field, and was borne to the house in an unconscious condition, and was so found by the physician. He was given thirty grains of calomel, and in two hours' time he became conscious, and awoke with a violent pain in the region of the liver. The pain in the liver was so extreme and excruciating that he was given chloral and deodorized opium. Pretty soon this strong narcotic, which I have never seen fail to relieve pain, began to have its effect, and soon the patient was drunk. He felt good and happy—the negroes on the plantation, especially the women, were all assembled around his bedside, expecting him to die, and, after their manner, began to sing, and the patient joined them in the song. He sang lustily, and, being drunk, and feeling good, he called out to one of the negro women: "Aunt Jane! Aunt Jane! I ain't gwine to heben wid no lie in my mouf. I stole dat pullet of yourn, and you will find it under dis bed tied to de hine bed-post wid er string. Yes, you take dat chicken. I'se gwine to heben in white róbes." The calomel acted fully and freely, and the patient was soon well.

I would call attention to this pain in the liver. I have never witnessed it prior to the last five or six years. It rises with the fever, and when not otherwise relieved it passes off with the fever. I at first thought that its extreme violence might be due to gall-stone, but, in every case in which I have found it, there was no trace of gall-stone. On the contrary, the pain rising with the rise of the fever and abating with the fever shows that the pain is caused by the congested state of the liver acted on by the fever. Morphine has failed in every instance to relieve this pain, but it is always relieved by the chloral and opium.

[Written for the MEDICAL BRIEF.]

The Specific Indications for Wine.

BY C. D. R. KIRK, M. D.,
Shuqualak, Miss.

The doctor who prescribes wine or whisky promiscuously because he is fond of it, may be a very good fellow, but a poor excuse for a physician. The indications for wine are not only those for a stimulant, but those for an acid, and many times those for a sedative, or one that will control the rapid, weak heart. It is in no case a remedy for the patient that is saturated with acids. But how are we to know the man whose blood and secretions are loaded with alkalies or acids? Must we draw some blood and carry it through a chemical process? If so, only a small per cent of physicians would recognize the case. Those who have a contracted red tongue are, in almost any case, benefited by taking wine. A case of indigestion, with the red, contracted tongue, can take wine in small quantities, with more or less benefit; in fact, any chronic case with that kind of a tongue will find a small drink of wine just before meals, to be beneficial. A case of fever, especially typhoid fever, who has the contracted red tongue, moist and associated with a rapid, weak pulse, should have wine in large quantities. The heart sounds are almost blended, so that the last sound can with difficulty be separated from the first. These cases have cold extremities and labored respirations, and are semi-delirious, and they need the old doctor very much! They should have wine; a good article, given in increasing dose. Begin with a small wineglass every hour at first, but gradually increase the dose until the heart's action is brought back to something near normal. This requires a large quantity, but it is worth all the rest of the *materia medica* in such cases. After the patient's pulse has improved, breathing is normal, and sleep is induced. Omit the wine until all impressions from it have passed away, then, as the fever rises the next day, and the pulse again runs to extremes, repeat the wine, but omit it when the patient sleeps and the pulse gets slower and of full volume.

When wine is indicated, all other remedies should be suspended, for when needed it is almost invariably curative. This rule holds good in dysentery or pneumonia, or any other case, the same as in typhoid fever; therefore it makes no difference what a grouping of symptoms may name the disease, if there is a moist, red tongue, with rapid small pulse (or the full pulse, without power), wine in liberal quantities will be beneficial. An anthrax presenting the above pathological or diseased condition, should have wine in supportive doses. But what about the case with the abnormal pulse and a full, frosty-white coating of the tongue? Then wine is not indicated, because it will add to the already overplus of acids. In this case soda, alkaline diuretics and alcohol in the form of good brandy or whisky should be given. The pulse being the thing to guide us, the alcohol should be given until there is a full pulse, with strength and power. Then we may look for all other symptoms to improve. A fluid diet should be given hot, and often repeated in small quantities.

A Plea for Mild Medication.

BY JOHN M. REID, M. D.,
Eureka, Kan.

I believe it to be the mission of a physician to give his patients the best and least painful service at all times. I wish to present a case that befell a lady south of our city not long since. Her doctor reports that she was taken with cholera morbus. He gave her the usual remedies, but she constantly grew worse. He returned only to find her case aggravated. After a week's medication, he resorted to most strenuous measures, such as chloroform, ether, opium, laudanum, morphine, hypodermics of glycerine, warm water, salt solution, etc., until her arms, abdomen and gluteal muscles were masses of inflamed sores, caused by prickings of the needle.

Now, brethren, this is penned, not in the spirit of fault-finding, but in mercy for the patient.

Another physician was called and gave almost immediate relief by a few drops of leptandrin. The stools were dark, like tar, very fetid, and would remind you at once of the results following a large dose of leptandrin, therefore, the case was easy, and one that almost any one should have solved readily.

Brethren, for humanity's sake do not torture your patient, and do not fly to opiates, thus masking the symptoms that are the only sure guides to a speedy cure.

Natural Foods.

BY N. A. BOLLES, M. D., D. O.,
Denver, Colo.

The herbs and fruits are the only natural foods for mankind. Other foods are allowable only because one has inherited or acquired a taste for them, and only when hungry for them, after trying to be satisfied with herbs and fruit. These other foods are the roots and non-starchy bulbs, the tubers, nuts, grains and all animal foods.

First Choice—Herbs and fruits, as cabbage, lettuce, celery, kale, cauliflower, pieplant, dandelion, spinach, Brussels sprouts, lamb's-quarter, shepherd's purse, asparagus, cucumbers, tomatoes, squash, pumpkin, melons, canteloupes and green beans and peas. Apples, pears, peaches, plums, apricots and oranges, pomelo (grape-fruit), lemons, figs, prunes, dates and pineapple. Bananas only under protest; too apt to be starchy.

Second Choice—Roots and non-starchy bulbs; such as carrots, beets, turnips, radishes and onions.

Third Choice—Tubers, such as potatoes and sweet potatoes.

Fourth Choice—Grain and nuts, wheat, rye, barley, oats, rice, corn, peanuts, pecans and any other kind of nuts.

Fifth Choice—All animal foods of whatever class and variety.

1457 Ogden Street.

Book Notices.

A TEXT-BOOK OF THE PRACTICE OF MEDICINE. For Students and Practitioners. By Hobart Amory Hare, M. D., B. Sc., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital; Laureate of the Royal Academy of Medicine in Belgium and of the Medical Society of London. Author of *A Text-Book of Practical Therapeutics; A Text-Book of Practical Diagnosis*, etc. In one very handsome octavo volume of eleven hundred and twenty pages, with one hundred and thirty-one engravings and eleven full-page plates in colors and monochrome. Second Edition, revised and enlarged. Lea Brothers & Co., Philadelphia and New York: Price, cloth, $5.00; leather, $6.00; half morocco, $6.50.

One of the most uncommon and highly valuable mental faculties is judgment of relative importance, an ability to conceive ideas distinctly enough to measure them, and to picture them in their proper perspective. Such a faculty collects, arranges, sorts, drops what is unimportant, and seizes what is essential. Clear vision is clear thought, which finds its expression in clear language. Such qualities embodied in a book account for keen public appreciation, and this is the explanation of the fact that two very large printings and now a thoroughly revised edition of Hare's Practice have been demanded in less than two years. The author has written for medical students of all ages. He knows the needs of the undergraduate and the best mode of presenting a subject to his mind by reason of the fact that he has been teaching clinical medicine and therapeutics for nearly a quarter of a century, and the same length of active hospital and private practice gives the weight of experience which attracts the physician in need of counsel. Well-proportioned consideration is given to the theory and principles of medicine as underlying, explaining and leading up to the main objective point, namely, the practical application of the knowledge. Accordingly, particular pains have been taken to present methods of treatment clearly, and in such a way that they may be put directly into practice. Such have been the characteristics of the work from its original issue. In this new edition every line has been revised, anything already rendered obsolete by the rapid march of medicine has been eliminated, and all trustworthy advances have been incorporated, so that the volume, as it stands, is representative of its subject to date. Of its authority and resourcefulness, nothing need be said further.

DISEASES OF THE LUNGS. Designed to be a Practical Presentation of the Subject for the Use of Students and Practitioners of Medicine. By Robert H. Babcock, A. M., M. D., Author of "Diseases of the Heart and Arterial System"; until recently Professor of Clinical Medicine and Diseases of the Chest, College of Physicians and Surgeons (Medical Department of the Illinois State University), Chicago, etc., etc. Twelve colored plates and one hundred and four text illustrations. First Edition. New York and London: D. Appleton and Company. Price, $6.00.

This work is a companion volume to that upon Diseases of the Heart, published a short time ago. After thorough reading of this work we believe it is more comprehensive than any we have yet seen, as the author's individuality and his attractive style is fully shown throughout. The many records of interesting cases are helpful in diagnosis to the general practitioner. Differential diagnosis and treatment are given the attention their importance demands, and as a consultant it will prove worthy. It seems to us that the work stands alone in its class.

MANUAL OF CLINICAL CHEMISTRY. By A. E. Austin, A. B., M. D., Professor of Medical Chemistry and Toxicology in the Medical Department of Tuft's College, Boston. Boston: D. C. Heath & Co., Publishers. Price, $1.75.

The average work on chemistry is not written for the needs of the physician, therefore when we run across a work that has a close connection with medical practice we take pleasure in calling the attention of our medical friends to its applicability along medical lines. Not alone is this work a good one for the practitioner, but the first and second-year student will appreciate it as helpful. Students especially will find much of worth in this volume.

A MANUAL OF NORMAL HISTOLOGY AND ORGANOGRAPHY. By Charles Hill, Ph. D., M. D., Assistant Professor of Histology and Embryology, Northwestern University Medical School, Chicago; Formerly Professor of Zoology, University of Washington. Illustrated. Philadelphia and London: W. B. Saunders & Co. Price, $2.00.

This is one of the flexible leather books that are so much in vogue to-day, yet the value of a book is governed more by the contents than the manner of its presentation. This book is valued more for what it contains than any attempt at the convenient shape and adjustment to conveniences. Along the elementary line it has the facts of the subject in a clearer manner than any other work of its class that we have had the pleasure of reading. It is well worth the time spent on reading up the subject of Histology.

MEDICAL DIAGNOSIS. A Manual of Clinical Methods for Practitioners and Students. Fifth Edition, greatly enlarged and revised to date. By J. J. Graham Brown, M. D., F. R. C. P. E., F. R. S. E., Assistant Physician, Royal Infirmary of Edinburgh; and W. T. Ritchie, M. D., F. R. C. P. E., F. R. S. E., Clinical Assistant Pathologist, Royal Infirmary of Edinburgh. With two hundred illustrations and eight full-page plates. New York: Imperial Publishing Company. Price, $3.00.

A book is certainly popular when five large editions have been issued, and when we find that it has been carefully revised we fully predict for it a future that should guarantee more editions. The illustrations are profuse and enhances the value of the text matter. It certainly will prove valuable to the busy practitioner, as it will guide him quickly to up-to-date matters in regard to diagnosis. The medical student will find much material to guide him and lend aid to his future in diagnosing cases. It is invaluable to both practitioner and student.

MEDICAL DIAGNOSIS. A Manual for Students and Practitioners. By Charles Lyman Greene, M. D., Professor of the Theory and Practice of Medicine in the University of Minnesota; Attending Physician St. Luke's Hospital, the City Hospital and the St. Paul Free Dispensary; Member of the Association of American Physicians, the American Medical Medical Association, American Association for the Advancement of Science; Author of "The Examination for Life Insurance and Its Associated Clinical Methods," etc. With seven colored plates and two hundred and thirty illustrations. Philadelphia: P. Blakiston's Son & Co. Price, $3.50.

This volume embodies the author's conception of the type of book most generally useful to the over-taxed student and general practitioner, and a glance at its pages will show that he has made it concise, practical and thoroughly modern, not to mention its convenient size and form. It is not a mere compend, as it covers the ground-work in a very elaborate and thorough way. It is complete and logical and should have the recognition that it deserves. We commend it to our friends.

THE PRACTICAL MEDICINE SERIES. Comprising ten volumes on the Year's Progress in Medicine and Surgery. Under the general editorial charge of Gustavus P. Head, M. D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Vol. VIII—MATERIA MEDICA AND THERAPUTICS, PREVENTIVE MEDICINE, CLIMATOLOGY, FORENSIC MEDICINE. Edited by Geo. F. Butler, Ph. G., M. D., Henry B. Flavill, A. B., M. D., Norman Bridge, A. M., M. D., Daniel R. Brower, A. M., M. D., LL. D., Harold N. Moyer, M. D. Also Vol. IX, ANATOMY, PHYSIOLOGY, PATHOLOGY, DICTIONARY. Edited by W. A. Evans, M. S., M. D., Adolph Gehrmann, M. D., William Healy, A. B., M. D., Chicago. The Year Book Publishers. Price, $1.25 each.

A simple announcement that a new volume of the Practical Medicine Series, and the subject of the work, is enough to get the attention of physicans drawn to its usefulness to any library.

THE MEDICAL AND SURGICAL USES OF ELECTRICITY. Including the X-Ray, Photo-Therapy, the Finsen Light, Vibratory Therapeutics, High-Frequency Currents and Radio-Activity. By A. D. Rockwell, A. M., M. D., with two hundred and fifty-nine illustrations. New edition, revised and enlarged. New York: E. B. Treat & Co. Price, $5.00.

There is no work along this line that has the prestige accorded this one. Practically, this is the eleventh edition of this work. It is the most elaborate and complete work on this subject that has ever been issued. If you want to get thoroughly posted in medical and surgical electricity it would be well to secure this book.

Editorial.

Danger in Prescribing United States Pharmacopœia and National Formulary Preparations.

There is a drug paper published in Chicago called *N. A. R. D. Notes*. It is the official organ of the National Association of Retail Druggists, the largest and most powerful association of retailers that was ever organized in this or any other country. As the organ of the druggists, it has been devoting much space to the question, which is being agitated in the trade just now, of popularizing, with physicians, the United States Pharmacopeia and National Formulary Preparations. But it appears to be fair in its treatment of the subject, for it publishes communications on both sides of the question. Among the communications *against* the idea, is one from Dr. J. J. Gill, of Chicago, who was himself once a pharmacist, but who, a short time ago, abandoned that profession and took up the study of medicine. He is now in active practice, and has built up quite a large clientage. In the communication referred to, Dr. Gill tells his readers that when he began to practice medicine he resolved not to prescribe proprietaries, but determined to confine himself to the use of the so-called official preparations. He says, however, that he soon found this to be impracticable, for the reason that *druggists were not acquainted with the United States Pharmacopeia and National Formulary*, did not recognize many of the preparations contained in them when they were prescribed by name, and did not know how to prepare them; and that he had soon to give up the idea he had cherished of being strictly "ethical" as to the remedies he employed. We publish this doctor's letter in full, for, having been a pharmacist, he is in a better position to discuss the matter than could physicians generally, who are not so well acquainted with the conditions that prevail in the drug trade. We commend this letter to the thoughtful

consideration of physicians everywhere, and ask them if they are willing to be persuaded or bulldozed in prescribing preparations that druggists are not able to prepare, in place of those they have often tried, and whose merits have been clinically proven.

The following is Dr. Gill's letter:

DIFFICULTIES TO BE OVERCOME IN POPULARIZING U. S. P. AND N. F. PRODUCTS.

EDITOR N. A. R. D. NOTES.—As a pharmacist I labored for fifteen years in Hyde Park endeavoring to induce the physicians to write prescriptions rather than dispense their own medicines, and also to demonstrate to the prescriber the value of prescribing official rather than proprietary preparations. But the success that attended my efforts was not great. I found the physicians indifferent and few of them were convinced that my arguments were sound. This apathy mystified me, and I failed to understand why the physicians could not see the situation as I saw it.

But when I began the practice of medicine several years ago I began to have a different view of the question; then, and not until then, did it dawn on me why physicians prescribe proprietory medicines and others do no prescribing at all. I have been surprised and chagrined at the things which have come under my observation, and had I not the best interests of the druggists at heart, I would remain silent rather than say anything on the subject.

OFFICIAL PRODUCTS UNKNOWN IN SOME STORES.

Long before I finished my medical course I made a vow that I would never, under any circumstances, prescribe any preparation other than those found in the National Formulary and the Pharmacopœia. However, in the course of my practice, I found my vow to be a source of never-ending vexation and annoyance to me as well as to the pharmacists, *for the reason that these official products are almost unknown at some stores.* On one occasion a clerk called up and asked if he might substitute P. D.'s elixir, giving as his excuse that they kept no goods manufactured by *N. F.*!

On another occasion I prescribed Eloesaccharum Anisi and *the prescription was held for twelve hours because of the difficulty in getting this rare* (?) *preparation.*

A short time ago I gave a patient a simple prescription which was taken to a near-by store for compounding. There the patient was told by the druggist that the prescription called for a very rare preparation, and that it would take, at least, two days to fill it.

AN ANTIQUATED DISPENSATORY.

When I saw the patient on the following day I found that he had not yet taken any of the medicine and he complained because I had given him a prescription so difficult to fill. I called up the pharmacist and learned just what I had suspected, namely, that there was nothing but an antiquated Dispensatory in the store, and consequently the rare (?) preparation, Elixir Adjuvans, had never been heard of. Any fair-minded person will admit that the action, or ignorance, if you please, of the druggist was absolutely inexcusable, and an injustice to me.

Pharmacists are continually complaining of the use of proprietary articles, but *should the physician be blamed if he uses them when he finds it almost impossible to get anything else?* As a good example of what the physician has to contend with in this way, I will say just a word about the difficulty I have experienced in trying to obtain the official preparation Liquor Cresolis Compositus.

Every one who possesses a Pharmacopœia (and a druggist who has no copy of this book can not call himself a pharmacist), knows that this is a product easy to prepare and is much cheaper than Lysol, yet about two-thirds of my orders for it have met with difficulty. One druggist dispensed Creolin, and several others turned away the prescriptions. But the climax was reached when one druggist told my patient that Liq. Cresolis Comp. was a secret preparation to be had only at my store, and that I prescribed it in order to force the patient to take all prescriptions to my pharmacy. Could anything be more unjust to a physician who is trying to assist the druggists in bettering conditions in the business?

WHY AGITATE PATENT MEDICINE QUESTION?

And this leads me to raise the question: Why waste so much time, money and energy in agitating price protection for patents when the real live issues of pharmacy are neglected? If the druggists would spend half the energy they devote to the patent medicine question, in an effort to show the physicians that they understand their business, they would find that the relative unimportant patent medicine price craze would be lost in oblivion. Druggists can not expect the support of physicians unless they know something about pharmacy.

JOHN J. GILL, Ph. G., M. D.

Chicago, August 5.

His Magnificenz, Rector Von Sybel, of the University of Marburg, wrote to Dr. Rose that the "Memorial on Medical Language," the first part of which appeared in the September issue of THE MEDICAL BRIEF, had been distributed among the rectors magnifici of all the German universities assembled in Marburg on July 31st. Some distinguished German physicians have already expressed their approval of the idea presented in Dr. Rose's memorial.

[Written for the MEDICAL BRIEF.]

The Action of Alcohol in Health and Disease.

BY WALER E. DIXON, M. A., M. D., B. SC., D. P. H.,

Professor of Materia Medica and Pharmacology in King's College, London, and Assistant to the Downing Professor of Medicine in the University of Cambridge. Cambridge, England.

The question whether alcohol, in moderate doses, affects the body injuriously or not is one of great importance, not only to the individual, but to the nation at large. The advocates of teetotalism would have us believe that alcoholic beverages only make for evil, that they shorten life, tend to promote disease, and, even as a remedy, are more likely to cause harm than good.

So long as these statements are made merely as matters of personal opinion they may be disregarded; but when they are made by scientific and medical men it is right that the facts of the case should be stated, and that true temperance should be distinguished from total abstinence.

Everyone is agreed that anything taken in excess will lead to evil results, and we are not here concerned with the intemperate use of alcohol.

The first question which arises is, "What becomes of alcohol when taken by the mouth?" and to this a definite answer can be given. If alcohol is taken in moderate quantities it is almost completely oxidized in the body to carbonic acid and water, in much the same way as starch or sugar, and as the human body is continually burning up food substances in order to keep up its temperature, we are naturally led to believe that alcohol provides some of the necessary fuel for this purpose. Now, it might be supposed that this alcohol would be burned up at once, and so provide the body for a short time with an excess of useless heat.

This is not the case, for the alcohol is burnt just as it is required, in exactly the same way as starch or fat. For example, supposing a man is kept on a fixed diet, and made to perform the same amount of work every day, then his weight soon becomes and remains constant; if, now, some of the starchy food or fat is taken from his diet, he naturally loses some weight. If, however, this starch or fat is replaced by an equivalent amount of alcohol, his weight will remain unaltered. Hence, to a moderate degree, alcohol can replace starch or fat in a diet.

We are all familiar with the fatness of the beer-drinker, and, to a less extent, of the spirit-drinker, and in them the deposition of adipose tissue is, no doubt, brought about by the alcohol being oxidized in place of fat, though, in the case of the beer-drinker, the deposition of fat is due, partially, to the large amount of saccharine matter taken.

The perfect diet, besides containing water, salts, starchy and fatty food, must

also contain proteid. It has been shown already that alcohol can replace the starch or fat without any evil effect, such as loss of weight; but if some of the proteid food is taken away from the fixed diet and substituted by alcohol, the result may not be the same.

If the man under experiment is moderately addicted to the use of alcohol he does not lose weight—that is to say, the alcohol is used to spare his proteid. If the man is not used to taking alcohol the substitution leads to some loss of weight for a few days. His tissues, however, learn to deal with the alcohol very quickly, so that even in the teetotaler, after a few days' trial, alcohol not only can be substituted for some of his fat, but for his proteid also.

In other words, in all classes of people, alcohol is oxidized usefully in the body. It supplies the body with heat, and by providing a readily oxidizable substance, it spares some of the carbohydrate, fat, or proteid, which would otherwise be broken down to produce the requisite temperature. Alcohol has certain advantages over starch and sugar as a food, in that weight for weight it contains more energy, and because it is absorbed so easily and rapidly.

Starch and sugar are not digested and absorbed into the blood until they reach the small intestine; alcohol, on the contrary, is absorbed from the stomach. From this it can easily be seen what a valuable substance alcohol may be in any condition where an easily combustible food is desirable. The following table shows a comparison of some common foods with alcohol, as regards their heat value:

Material.	Water per cent.	Fuel value per lb. in calories.
Beef (round)	63.5	950
Cow's Milk	87	300
Wheat Bread	35.3	1,200
English Beer	88	275
Brandy	52	1,475
Whisky	59	1,250

In considering this table, from Dr. Atwater's work, it should be remembered that the figures only hold when the quantity of alcohol imbibed is moderate. When alcohol is present in such large quantities that the tissues are incapable of dealing with it, toxic effects will accrue which may more than counterbalance the benefits.

ACTION ON THE CIRCULATION.—For convenience of description this action will be taken under four sub-headings, (*a*) the rhythm of the heart, (*b*) the cardiac output, (*c*) the vessels, (*d*) the blood-pressure.

(*a*) *Effect on Cardiac Rhythm.*—Zimmerberg experimented with frogs, cats, dogs and men, and concluded that, when proper precautions were taken to avoid local irritation, alcohol did not alter the pulse rate. Von de Mühll and Jaquet experimented with eight convalescent men, and concluded that alcohol in amounts varying from fifty to one hundred cubic centimeters, diluted to twenty per cent, had practically no action on the heart or circulation. Maki and Hemmeter also state that alcohol does not alter the rhythm of the heart. Parkes and Wollowicz, Marvaud, Binz, Foster, and others, state that alcohol increases the pulse rate. Martin and Stephens gave fifteen cubic centimeters of alcohol to a young man, taking due precautions as to dilution; they failed to notice any change in the pulse rate.

Ringer and Richards state that in health alcohol slows the pulse, whilst Lichtenfels and Fröhlich and von Jaksch describe a preliminary slowing, followed by acceleration. Von Jaksch administered eight cubic centimeters of brandy to a number of children; he found decrease in the pulse rate in nine cases, and increase in one, and no change in two. After 3.2 grams of alcohol, properly diluted, the results were of the same character.

From this medley of observations it is at once evident that whatever the changes in pulse rate may be they are neither constant, nor of any great significance. The amount of time which has been expended on such observations is out of all proportion to their importance; but it was formerly believed that if it could be shown that alcohol accelerated the pulse, it had a right to the title "cardiac stimulant." When concentrated alcohol, twenty to fifty per cent, is taken by the mouth, the pulse, during the space of a minute or two, is always accelerated. This is not an action peculiar to alcohol, and it can be observed after the administration of any irritant, such as mustard and water.

or even after water alone, if it is sufficiently hot. As is well known, any mild peripheral stimulation causes acceleration of the pulse.

To test the value of these statements I have performed a number of experiments on men using different stimulants. The subject was placed in as comfortable a position as possible; one radial artery was adapted to the sphygmograph, so that the pulse could be recorded at will. Whilst the record was being taken the man was required to hold in his mouth for a few seconds, or to swallow, some of the stimulant. By this means it was easy to show that alcohol, as a fifty per cent solution, was a more efficient "stimulant" than the other substances (mustard, essential oil, hot water) which were tried, and that it quickened the heart considerably. If the alcohol was retained in the mouth a few seconds only and was then spat out, the effect quickly passed off, but if it was taken into the stomach the acceleration was prolonged for half an hour or longer. When the same amount of alcohol is given, well diluted, these effects are not seen.

If moderate doses of alcohol, well diluted with water, be administered to animals or men, the pulse rate does not alter. I have tried these experiments over and over again, and always with the same results. The popular fallacy that alcohol quickens the pulse is clearly derived from the conditions under which alcohol is usually taken. It is well known that excitement of any kind quickens the heart, and alcohol is generally taken under exciting circumstances.

If a heart is beating feebly, alcohol invariably accelerates the rhythm, quite apart from the reflex effects just described; for example, at the end of a long perfusion experiment, small doses of alcohol not only improve the quality of the beat, but increase the rate.

Large doses of alcohol administered to the normal animal slow the heart beat. This action is not obtained on the isolated heart, nor when the vagi have been severed, but only in an animal having an intact medulla. Now alcohol administered in large doses behaves, in many respects, like chloroform, and belongs to the same group of narcotics. It differs from chloroform because within certain limits it is oxidized in the tissues. If, then, it is required to determine its action upon nervous structures, neither chloroform nor other anesthetic substance should be present in the tissues. Large doses of alcohol, administered to an animal under the influence of chloroform, have little power of slowing the heart, but to the unanesthetized animal the slowing may be very decided, or there may be even complete inhibition.

Cerna, Jaquet and others have denied that alcohol excites the medulla, but, in view of the conclusive experiments conducted by Binz and his colleagues on respiration, it must be conceded that alcohol, to both men and animals, is a decided stimulant to the medulla. Such stimulation being granted, Schmiederberg and his pupils would regard it as due to dissolution of the higher centers, and not a primary effect on the medulla. My experiments show, conclusively, that large doses of alcohol increase the activity of the medulla for a period, during which the heart-beat becomes slower, and this effect can not be due to dissolution, since the animal is decerebrate. Large doses of alcohol ultimately produce depression of the medulla and the heart quickens again. In smaller doses the effect on the vagal center is not apparent, though the effect on the respiratory center, as Binz has clearly shown, is decided.

From these facts it is evident that after administering alcohol many factors are at work tending to alter the rate of the heart. First, the strength of the alcohol must be considered, concentrated doses exciting the mucous membrane of the mouth and stomach, and causing reflex acceleration; then the conditions under which it is imbibed, exciting or otherwise; the quantity taken, and the amount of peripheral dilation are other important factors which require controlling.

(*b*) *Action on the Heart.*—Martin and Stevens perfused the dog's heart by the method devised by Martin. They found that 0.125 per cent alcohol, by volume, in the perfusing blood, had no effect, but that double this strength diminished the work of the heart in one minute. They assumed that this amount of alcohol was equivalent to taking five ounces of brandy.

Hemmeter and Bock confirmed these results; they considered that alcohol had no special effect on the heart. Hemmeter, working with Ludwig's Stromuhr, showed that alcohol increased the velocity of the circulation in the dog's carotid, and this has been confirmed by Wood and Hoyt. Loeb perfused the isolated cat's heart with saline, and found that alcohol, in amounts varying from 0.13 to 0.3 per cent, generally increased the force of the beat. Larger doses depressed the heart. Somewhat similar results have also been obtained by Kochmann, Tunnicliffe and Rosenheim, with the same methods, obtained little effect on the rabbit's heart.

The first series of experiments were conducted upon the isolated rabbit's heart, perfused with Ringer-Locke's solution, by means of the Langendorff apparatus. The hearts were allowed to record for about one hour, and when the beat was quite constant the saline solution was changed to one containing the alcohol. It was found that certain strengths of alcohol generally increased the amplitude of the contractions. This effect was observed in strengths varying from 0.05 to 0.3 per cent in the rabbit. It was most marked in feeble hearts, which had been beating for some hours without nutriment, and was least marked, or even entirely absent, from vigorous organs, especially when these were freshly isolated or provided with nourishment, such as glucose. There can be little doubt that within certain narrow limits the heart can adapt itself so as to deal with and make use of the alcohol, just as we know the body, as a whole, is able to do. But complete proof of this will only be forthcoming when it is shown that the alcohol in the perfusing fluid, disappears, in part or whole, after passing through the heart; such experiments are being arranged in my laboratory.

If alcohol in greater concentration, such as two per cent, be perfused through the coronary vessels for a short period, such as thirty seconds, the force of the beat is greatly diminished. The muscle fiber is not injured, however, because when the alcohol is replaced by saline, not only does the heart recover completely, but the beats become much more vigorous than before. These experiments on the isolated rabbit's heart have been repeated on the cat, and the results obtained are of the same nature.

Another series of experiments was conducted on the hearts of cats and dogs with the circulation intact. In these experiments the brain was usually destroyed, but in a few cases the animals were anesthetized with chloroform and urethane. The heart was enclosed in a glass cardiometer, and the movements of the air recorded, so that as the heart fills with blood the recording lever rises, and during systole of the heart the lever falls. The results of such experiments show that the action of alcohol, whether administered intravenously or subcutaneously, is to increase the output from the heart; relaxation is greater than before, and the systole is somewhat increased.

It is clear that alcohol possesses two entirely different actions, it excites in small doses, but depresses in larger ones. In this respect it resembles no other drug, for when we increase the dose of other drugs the effect is at first exaggerated, and only with enormous doses does paralysis ensue. But with alcohol there is a definite limit to the dosage, to overstep which is depression. In other words, to increase the dose with alcohol is to cause a different type of effect.

It is well known that alcohol is oxidized in the body and yields energy; and the experiments of Atwater and Benedict have made it abundantly clear that the alcohol is not burnt up uselessly, but that it can be isodynamically substituted for carbohydrates or fats. In this sense, then, alcohol is a food. But the tissues can oxidize only a limited amount, and if this is exceeded the toxic effect of the alcohol becomes evident. Immunity to organic substances, such as morphine and alcohol, is the expression of the increased ability of the tissues for their oxidation; and the tissues may be cultivated to a greater or less tolerance by the continual administration of the drug.

The "stimulant" action of small quantities of alcohol on the heart is readily explained by regarding it as an expression of the food value of the drug, and for the following reasons: We know it acts as a food to the tissues as a whole; why, then, should it not so act to each separate tis-

sue, *e. g.*, the heart? In animals rendered somewhat immune to the action of alcohol, it behaves as a more decided stimulant to the heart than in control animals, thus suggesting that the heart behaves like the tissues, as a whole. Moreover, its action on the heart shows many resemblances to certain other foods, such as sugar, the effect being most decided when the heart has been beating for some time whilst deprived of food. The addition of sugar to the perfusing saline fluid during a Langendorff experiment, is to cause an increase in the excursion of the lever, and the same effect, though less defined, is obtained with alcohol. But alcohol differs from sugar, because if the dose is increased toxic effects come into play. Alcohol, given by the mouth, has this advantage over other foods, that it very rapidly finds its way into the circulation, and, unlike sugar, it can be absorbed directly from the stomach.

I would point out that alcohol is normally found, though in minute quantities, in the fresh tissues of man and animals that have received no alcohol. It can be distilled off from the liver, muscle, brain, and other tissues. Since we know that small quantities of dextrose and alcohol are readily oxidized in the tissues, it is not improbable that dextrose is oxidized in successive stages, and that the oxidation passes through the alcohol stage, energy being liberated at all stages in the oxidation. As we are daily obtaining more and more evidence that the so-called "vital" phenomena are in reality fermentations, it seems to me feasible that such oxidations might be brought about by a series of co-ordinated ferment actions. That such an explanation is possible is seen from the fact that the ferments in yeasts will oxidize dextrose to the stage of alcohol, and those in mycoderma aceti will continue the oxidation.

(*c*) *Action on the Vessels.*—When administered to the intact animal, alcohol does not affect all vessels in the same way. But if it is perfused through the vessels of organs which are isolated from the body, the effect is the same in all cases. In frogs, one-half per cent alcohol in the perfusing fluid determines an immediate, though moderate constriction, which is very permanent in character, but which is removed by substituting pure Ringer's solution for that containing alcohol. In mammals small amounts of alcohol, such as 0.1 or 0.2 per cent, cause very slight dilatation when perfused through isolated vessels. If the percentage be stronger, about one or two per cent, then constriction, quite considerable in extent, first ensues, followed later by dilation. All vessels, pulmonary and coronary, as well as systemic, are affected in just the same way, so that the action must be on muscle. In part, these results agree with those of Kobert, who found that alcohol in dilute solution, 0.1 and 0.2 per cent, had little effect when perfused through the renal vessels.

These experiments show that the action of alcohol upon the blood vessels must be partly central. Drugs which affect the center do not influence all blood vessels in the same way. Thus, atropine excites the medulla and basal ganglia in the brain, but whilst constricting the splanchnic vessels it dilates the superficial ones. Alcohol also dilates the skin vessels very rapidly, and at the same time tends to constrict the vessels in muscle tissue, and to a less marked degree in the splanchnic area.

The effect on the skin vessels has been investigated by the plethysmographic method on the ears of dogs and rabbits; in anesthetized animals alcohol caused decided constriction, whilst the volume of the limb in the dog also diminishes, and this effect is obtained no matter whether the drug is injected under the skin or given by the mouth. The effect of a subcutaneous injection of alcohol is to produce a gradual rise in blood-pressure, with but little apparent change in the condition of the vessels. In this case there must be a marked tendency towards constriction, since, if the vessels were in their normal state they would become considerably dilated, passively, from the rise in blood-pressure. By perfusion experiments it has been already demonstrated that this effect may be peripheral on the vessel walls, but it is more likely partly central. It can easily be shown that alcohol exerts a stimulant action on the brain, by injecting a little, well diluted with Ringer, up one carotid artery towards the brain.

The effect of alcohol, as ordinarily administered to man, on blood vessels, must be mainly central. In moderate doses the superficial vessels tend to dilate, and the internal vessels tend to constrict. This dilation of the superficial vessels is sometimes the exact opposite to that occurring in dogs when large doses of alcohol are administered, either by injection or by the stomach tube. The explanation of this is simple. We know that drugs which excite the medulla and basal ganglia of the brain whilst constricting the internal vessels, simultaneously dilate the superficial ones. This is the reaction of the organism against rise in temperature; stimulation of the corpus striatum augments metabolism, and drugs which induce this effect invariably dilate the skin-vessels. Atropine may be regarded as a typical drug, which, by exciting the brain centers, causes constriction of the internal vessels, and dilation of the superficial. Now, small doses of alcohol, as I have already pointed out, excite the medulla, and should tend to dilate the superficial and constrict the splanchnic vessels. This effect is obtained in animals if certain precautions are taken with regard to keeping the medulla as normal as possible, and giving only a small dose of alcohol, and that for preference by the mouth; it is the effect which is generally observed in man. It might be suggested that the alcohol was quickly oxidized in a useless fashion, and produced a sudden output of heat, and so dilation of the skin vessels. This is not the case, for we know that alcohol is oxidized as it is required by the body, and may be substituted in a diet, isodynamically, for starch or sugar.

(*d*) *Action on Blood-Pressure.*—No observations on the action of alcohol show greater discrepancies than those dealing with blood-pressure. These may, possibly, be explained by the very different conditions under which the various experiments were conducted. Those of Zimmerberg, Dreser, and Abel, were performed on anesthetized animals, and, on the whole, agree with one another, the main effect being a fall of blood-pressure. Experiments on anesthetized animals can not be regarded as showing the exact action, and especially would anesthetics hide the delicate effects produced by alcohol as a food substance, on account of their known action on metabolism. Another error is the tendency of observers to give excessive doses of alcohol. Thus, Gutnikow says that alcohol produces a fall of blood-pressure in the curarized dog, but to produce this effect he administered two hundred and fifty grammes of fifty to seventy per cent alcohol, and does not mention the weight of his dog. The majority of observers state that small doses of alcohol cause some rise of blood-pressure, and some that this is followed by a more considerable fall. Dogiel and Cerna did not employ anesthetics in their experiments. They describe an increase of blood-pressure. Schafer has shown how very decidedly alcohol acts in preventing the fall of blood-pressure caused by chloroform.

The present experiments were performed on cats, dogs and rabbits. Anesthetics were not usually administered, but the animals were in each case killed by pithing, the cerebral hemispheres being completely destroyed. In some cases the medulla was destroyed, and in others, especially in experiments dealing with vasomotor phenomena, it was kept intact; in the latter case the animal's respiration was natural.

Large injections of alcohol into a vein cause an immediate fall in blood-pressure. As soon as the heart is acted upon by the concentrated alcohol, the muscle fibers lose their power of contractility, and the organ becomes gorged with blood, but as the alcohol becomes diluted the force of systole increases, and the blood-pressure rises again. This initial fall of blood-pressure is due to cardiac failure, and is analogous in every way to that caused by chloroform. It is, however, of little significance practically, since the enormous amount of alcohol necessary to produce this effect is such as never occurs in life.

A further series of experiments on pithed rabbits, cats and dogs was made, in which the alcohol was placed directly in the stomach by means of a tube. In some of these cases curare was given. In all cases this method of administration resulted in a decided action on the circulatory system, and especially was this the case when the circulation was failing, as is apt to happen as the result of collapse,

some hours after the destruction of the brain. When absolute alcohol is placed directly in the stomach there is an immediate rise of blood-pressure, which passes off in two or three minutes. This is a reflex effect, and does not occur if the medulla is destroyed, nor if it is fatigued by morphine or other anesthetics.

Alcohol, no matter how it is administered, causes a small rise in pulmonary pressure. The systemic pressure is but little affected, yet the pulmonary pressure is distinctly raised. At this point the similarity between the action of alcohol and that of sugar on the blood-pressure may be pointed out.

The blood-pressure is the resultant of the output from the heart, and the condition of the vessels, as a whole. The cardiac output is increased, and the sum-total effect on the vessels is rather towards dilation than constriction, so that the blood-pressure may either rise or remain constant, according to which of these two factors holds the balance. But there is one effect which is seen fairly constantly in the blood-pressure tracing, even when the systolic pressure is unchanged, that is, the increased difference between systolic and diastolic pressures; this effect is also seen after the injection of sugar. In man, the same condition is expressed by saying that the systolic pressure is a little increased or constant, whilst the diastolic pressure falls. Indeed, the conditions of the circulation of man, under the influence of alcohol and in the normal state, as shown by his blood-pressure, present considerable analogies to his blood-pressure in the recumbent and standing positions, respectively. In other words, alcohol facilitates the circulation. I do not, however, wish to dogmatize as regards man, as my experiments are confined to two subjects.

My experiments and observations show that:

1. In moderate doses, and if well diluted, alcohol has little effect on the rate of the normal heart; in large doses it excites the medulla and slows the heart through the vagus. The failing heart is accelerated by alcohol. When taken by the mouth, in concentration, alcohol reflexly quickens the beat.

2. In moderate doses alcohol causes dilation of the superficial vessels and some slight constriction, which, after large doses, is followed by dilation of the internal organs' vessels.

3. In moderate doses alcohol increases the activity and output of the heart. Reasons are given for suggesting that this effect is due, in whole or part, to the fact that alcohol is a readily assimilable food-substance. In large doses, strengths over 0.5 per cent in the blood, alcohol depresses the heart. This is due to the toxic action of the drug.

4. Alcohol, in moderate doses, administered to animals which show signs of circulatory failure, raises blood-pressure, mainly on account of its effects on the heart. In normal animals, and in man, whilst the systolic pressure may rise a little or remain unchanged, the diastolic tends to diminish; in other words, the difference between the systolic and diastolic pressure tends to increase.

To sum up the conclusions with regard to the General Action of Alcohol in Health and Disease, the following facts may be safely stated:

Alcohol is rightly regarded as a circulatory stimulant. In the feebly-beating heart, or exhausted heart, its effect is very decided, and the condition of the beat, in both cases, is much improved. When it is allowed to act upon the heart in a healthy condition its effect is less decided, though in this instance, also, it is a stimulant—that is to say, the heart pumps out more blood per minute.

How does alcohol produce this effect? It may improve the beat by directly exciting the heart muscle, like preparations of digitalis, or it may act by providing a readily assimilable source of energy. We believe it acts on the heart as on other tissues, by providing it with an emergency food-stuff. Hence, its beneficial effect in the wasting diseases of children, in certain forms of heart disease, and in any condition in which, owing to an improper digestion, the circulation of sugar in the blood is interfered with.

Alcohol is popularly regarded as a stimulant to the brain—that is, a substance which increases the activity of the brain-cells. Is this view justified by experiments? All our reliable evidence shows

that moderate doses, an ounce to an ounce and a half of pure alcohol, or two or three ounces of whisky, have very little effect on mental activity; and the higher elements of mind, such as attention, judgment, and control, are, at most, only very slightly excited. Certain of the elements of mind are depressed, however, by even such small doses of alcohol as these.

The appreciation of unpleasant impressions is weakened so that, for example, sorrow becomes less acute; at the same time a general feeling of well-being pervades the individual. Larger doses of alcohol, five or six ounces, depress the higher or controlling centers of the brain, and, as a result of the lack of control, the lower centers exhibit an increased activity.

It is this lack of control of the lower brain centers which causes the excitement, and is commonly regarded as the stage of stimulation. It is a stimulant, but it affects only the lower centers, such as those dealing with movement, and not those of judgment and control. After such relatively large doses of alcohol man shows greater self-confidence, is more talkative, and less shy.

The emotional side of his character is especially well developed; thus, the jovial man becomes hilarious, the choleric pugnacious, etc., and it is, presumably, to this state that the Psalmist, David, in recounting the benefits of Providence, names "Wine that makes glad the heart of man." We believe that the pleasure of intoxication is due to this exuberance of emotion.

This explanation of the action of alcohol on the brain, that even in quite small doses it exerts a sedative effect on certain of the highest centers, such as the just appreciation of unpleasant associations, and, in larger doses, depresses judgment and control, is the one generally accepted.

The constant activity of our highest functions, though they yield most, fatigue us most, and especially is this the case in those of us endowed with vivid imaginations and hypersensibility of all kinds. In such conditions alcohol affords an easy remedy for mental fatigue. After the toil of day, exacting duties, the friction and hurry of life, mental tension and over-wrought nerves, alcohol may be beneficial, even to the highest faculties.

To take a stimulant for the relief of pain is, of course, nonsense; we but excite the brain to better appreciation of the painful sensation. A sedative, like alcohol, by diminishing appreciation of pain, is more rational in such conditions. Again, when our intellectual centers have been unduly excited and sleep becomes difficult, alcohol may produce just sufficient sedation to relieve this condition. In a word, for any condition requiring a mild sedative, alcohol is the least harmful of all drugs.

One other serious objection which has been made against the use of alcohol as a beverage, must be mentioned. It has been stated that it causes a diminution in our power of resistance to disease. This it is said to do by paralyzing tissue cells, more especially the white blood corpuscles, or scavengers, of our blood.

Alcohol, in large doses, in common with many other drugs, such as quinine and sodium salicylate, certainly has this action, and especially is this the case if it is injected under the skin, so as to reach the circulation in concentration; but alcohol, in small doses, just as certainly has the opposite effect, that is to say, it increases the activity of the white-blood corpuscles and other tissue cells, and augments our resistance to tubercle and other diseases.

These are the main facts concerning the action of alcohol. In moderate doses it is completely oxidized in the body, and under certain conditions serves as a useful food, and a valuable cardiac stimulant. In larger doses it has a toxic effect on the brain, which shows itself in sedation of the highest centers, and stimulation of the lower, but to call alcohol a poison, as this term is accepted in common parlance, without qualification or explanation, is a statement likely to deceive no one. At the same time alcohol is not a necessary article of diet for the healthy adult, and to the young it may do serious harm by creating a habit.

CARLYLE truthfully says: "If time is precious, no book that will not improve by repeated readings deserves to be read at all." We claim that repeated readings of the BRIEF will fully compensate the reader.

[Written for the MEDICAL BRIEF.]

Colles' Law and Its Exceptions.

BY GEORGE OGILVIE, B. SC., M. B. (EDIN.), M. R. C. P. (LOND.),
Chevalier de la Légion d'Honneur;
Senior Physician to the French Hospital, London:
Senior Physician to the Hospital for Epilepsy and Paralysis, London.
London, England.

No. II.

As I have previously pointed out, the statement made by Colles that he had never seen or heard of a case in which a healthy mother had contracted syphilis by suckling her congenitally syphilitic child, has been raised to the rank of a law, which goes by his name. It enjoys, up to the present day, universal recognition in the teaching of this country. Our authorities agree that it holds good, without exception. Berkeley Hill said that "This statement of Colles, made forty-four years ago, has never been controverted. Of the few cases called exceptions, not a single one bears investigation." Hutchinson said, "Since Colles' day no exceptions to his law have, I think, been put on record, which are worthy of trust." In the last edition of Cooper's book we read that "A careful examination of these cases —brought forward as exceptions—will demonstrate that, owing to want of very vital points in the recorded histories, the evidence rather tends to support Colles' law than to refute it."

A complete collection, with analyses of the cases, published as exceptions, does not exist. So far as I have been able to ascertain, their number is twenty. They differ in completeness, but some amongst them seem to me as conclusive as any clinical facts can be.

Cases such as these must be rare, even if the fact which they establish were of more frequent occurrence than it seems to be. To give them the conclusiveness which they possess, several conditions have to be fulfilled, which, for obvious reasons, can not often all be substantiated in an individual case. These conditions are the following:

1. The previous disease of the *father* has to be established.

2. It has to be proved by *medical evidence* that the disease of the child is syphilis. All cases have to be dismissed in which the previous history of the child, as regards symptoms, rests upon the evidence of relations, etc., because some non-syphilitic diseases of infancy closely resemble congenital syphilis.

3. It must be established that the disease of the child is *congenital*, and not acquired. In this respect we have only one, but an all-important point for guidance, the time of the appearance of the disease in the child, as the primary sclerosis might be missing or overlooked, and, as in every other respect, the acquired disease might closely mimic the congenital form. But even suppose that the child is infected at the day of its birth, taking for the first and second incubation the first shortest possible intervals of two weeks and three weeks, respectively, it could not present a syphilitic skin eruption, and an affection of the mucous membrane of the mouth, due to acquired syphilis, before the sixth week. Therefore, only those cases can be accepted as conclusive in which the general syphilitic disease of the child appeared within the first five weeks. Practically, however, the outbreak of secondary symptoms, up to two months or more after birth, can be attributed to the hereditary form of the disease.

4. It must also be certain that the ulcer appearing at the mother's breast is a *primary* sore, and here, again, we have only one criterion to rely upon, viz., that the indurated ulcer is followed in due time, not only by glandular swellings in the axilla, but by a rash, throat affection; in fact, by the ordinary sequelæ of the disease. It is well known that in people with latent syphilis, irritation of the skin may produce ulcerating sores. These sores may become indurated, as is the case, for instance, in the relapsing chancre, which, although occasionally appearing without any appreciable cause, might follow irritation or herpes of the prepuce. Therefore, the fact that the ulcer on the mother's breast is indurated, does not, in itself, prove its primary character, any more than the want of induration would disprove it. Swollen glands in the axillæ might follow any ulcerative process of the mammæ, whether syphilitic or not,

and if syphilitic, whether primary or not. The incisive difference between the irritation ulcer and the primary sore is that the former is not followed by secondary symptoms.

5. We have further to ascertain that the mother has not suckled any other child than her own, nor been exposed to contracting the disease from any other source. About these two points, in private practice particularly, information can be obtained which is not subject to any reasonable doubt.

That these conditions should all be fulfilled in the same case must evidently be rare. If it happens, an exception to Colles' law is established.

But, from another point of view, also the comparative scarcity of conclusive cases is easily explained. I do not think that any one nowadays doubts that a child affected with congenital syphilis may communicate the disease to a healthy wet-nurse by suckling, but about the frequency of this occurrence the greatest diversity of opinion exists. It appears that Colles considered accidents of this kind by no means rare. Continental syphilographers have described epidemics of the disease, spread in this way. On the other hand, a man of such large experience as Henoch, confesses to never having met with a case. According to Hutchinson, syphilitic infants, when put to wet-nurse, so rarely communicate the disease that some surgeons to lying-in hospitals, with very large opportunities for observation, have expressed disbelief as to its possibility.

This discrepancy can not be satisfactorily explained by the fact alone that in different countries, and in the same country, at different times, the proportion between children brought up by hand and those brought up at the breast shows great variations. It is partly accounted for by the circumstance that the syphilographer's experience must, necessarily, be at variance with that obtained in lying-in hospitals, children's and foundling hospitals. A collective investigation, embracing the institutions just named, could alone settle this open question, which the experience of no single man, however vast it be, can satisfactorily answer.

If infection of a nurse by suckling is rare, and if the above conditions have to be fulfilled to establish conclusive cases of infection of a mother by her own child, their comparatively small number is fully accounted for. Their number would, probably, be larger if the opportunity of closely watching mother and child for several months, in hospital practice at least, would offer itself more frequently; and it would be still larger if some cases had not been excluded, and been put down to acquired syphilis in the child, only for the reason that those who had not been given the chance of observing them were imbued with the teaching of Colles.

If Colles' law were valid it would have an important practical, as well as theoretical bearing. If it is only the expression of the personal experience of some at variance with that of others, the practical, as well as the theoretical, conclusions fall to the ground.

Practically, Colles' law teaches that the healthy mother can suckle her own congenitally syphilitic child with impunity. The so-called exceptions teach that she can not do so, and that, therefore, she, no more than a hired nurse, should be allowed to expose herself to the risk which she might run. In some particular case it may be justifiable to put a congenitally syphilitic child to the breast of a healthy wet-nurse who has been informed of the danger she runs. So it may be justifiable, occasionally, not to prevent a healthy mother from suckling her syphilitic infant. In cases of this kind, a conflict of various interests exists which can not be settled on purely medical lines. Moral, legal and sentimental considerations determine the decision to be arrived at. From a medical point of view, no justification exists.

The *theoretical* consequence of Colles' law would be that a mother who has given birth to a syphilitic child is immune against infection by it, although she has no symptoms of the disease, and never had any. This immunity has been regarded as proving the existence of latent syphilis in the mother. With what we know now on the relation between disease and immunity, such an argument is not admissible. In fact, the present phase of bacteriological knowledge seems to

readily offer a theoretical explanation, drawn from analogy. If the normal placenta represents a filter between the circulation of the mother and that of her child for all formed substances, the passage of microbes from one circulation to the other through the placenta (at one time regarded as impossible, but now definitely proved), presupposes damage to the cell layers. On the other hand, the noxious effect of the toxins produced by the organisms and carried by the blood, might pass from one circulation into the other by chemical interchange. Applying this to the question of transmission, one might argue that infection only takes place through the microbes and the lesions they cause, while the immunity is established by the toxines and their diffusion through the blood. Simple and plausible as such an explanation might sound, it is mere speculation, and at the same time insufficient, because, apart from other things, it leaves unexplained those cases in which neither infection nor immunization takes place.

Such cases occur, not only in syphilis, but also in other transmissible diseases. The child born healthy of a mother affected with small-pox, can contract the disease during parturition, or in early extra-uterine life, and must, therefore, be protected by vaccination. Vaccination of pregnant women with vaccine lymph produces immunity in the child against vaccination in, at most, only one-third of the cases.

Transmission of small-pox from mother to fetus is of erratic character. The child may be born dead, with or without small-pox. The child may be born alive with small-pox. The child may be born apparently healthy, and develop small-pox shortly after birth (say two days); in this case, also, the disease was contracted in utero. The child may be born healthy, and either remain healthy or contract small-pox in extra-uterine life; in the latter case it nearly invariably dies. To protect it it has to be vaccinated, which can be done successfully. The child may, during an epidemic, contract small-pox in utero, the mother, who was vaccinated previous to gestation, escaping. Of twins one only may be born with small-pox.

It seems that while intra-uterine transmission of small-pox is by no means rare, intra-uterine immunization seldom, if ever, takes place. The two antagonistic statements to be met with, that if a pregnant woman suffers from small-pox her fetus will also be affected, and that the child is always born free from the disease, are both wrong. They are merely expressions of personal experience and knowledge. Small-pox occurring during pregnancy is, in a large percentage of cases, instrumental in producing abortions and still-births. In the majority of such cases the fetus shows no signs of actual or past disease. Still, eruption or scars indicating intra-uterine infection, may be found on the dead fetus, as well as on the living child at the time of delivery. The child, if born free from the disease, and remaining healthy, is neither refractory to small-pox nor to vaccination.

A certain liking for symmetry, and the rounding of theories has, evidently, given rise to the extraordinary pendant to Colles' law, which is known abroad as Profeta's law, and which says that a child born healthy of a syphilitic mother is immune against its mother's disease, and can, therefore, be suckled by her with impunity. Going a step further, it has been contended that a healthy child is immune against infection by the secondaries of its father, if the later was syphilitic at the time of generation. That exceptions to Profeta's "law" exist was admitted by him, and also by Diday, when the latter gave the law its name. Since that time other observers have brought forward exceptions. In fact, I am not sure that they are less in number than those examples which might be adduced to support this so-called law. Anyhow, we know that a healthy child born of a syphilitic mother can contract syphilis from her in its extra-uterine life, and it naturally follows that the child has to be protected against this possible source of infection. That, in face of these granted facts, one could act and teach others to act upon the rule, affords a remarkable instance of conviction obscuring judgment.

It is possible that within certain limits Colles' law and its pendant express a clinical fact, viz., that under unknown conditions, during gestation, a reciprocity is

established between fetus and mother with regard to conveying immunity. The frequency with which this takes place has still to be found. But whatever the proportion may turn out to be between those cases which at present are considered exceptional and those cases which would exemplify the rule, our practical dealing is determined by the former. The practical consequences of the law break down since the exceptions are established. To ignore the exceptions or disprove them, and act upon the rule, is one thing. To accept the exceptions, and put aside the rule, is another thing.

In accordance with the actual wording of Colles' law I have restricted myself to the consideration of cases where the source of the mother's infection was her own child. No facts exist to show that a mother, immune against her child's disease, can still contract the disease from other sources. Granted that immunity against the child's or the mother's disease, respectively, means immunity altogether, then the rules referred to can, in a more concise form, be thus expressed:

1. A healthy mother, who has given birth to a congenitally syphilitic child, is immune against syphilis.

2. A healthy child, born of a mother suffering from acquired syphilis, is immune against syphilis.

With regard to this wider conception of what is understood as Colles' law, its fallacy is still more completely shown by those cases in which the mother of a congenitally syphilitic child contracts fresh syphilis shortly before or after delivery. Against this positive evidence the few negative inoculation results have no weight.

All the exceptions to Colles' law, in its wider sense, are conclusive examples of a purely paternal infection of the fetus, presenting the following features: Acquired syphilis in the father, congenital syphilis in the child, acquisition of syphilis by the mother shortly after delivery.

How WELL Alcott represents our journal when he says: "That is a good book which is opened with expectation and closed with profit."

[Written for the MEDICAL BRIEF.]

Gastric and Duodenal Ulcers.

BY VINCENT F. LENNANE, L. R. C. P., L. R. C. S. (EDIN.) AND L. M. (GLAS.).
Late Colonial Surgeon, Gold Coast.
London, England.

It is said that ulcer of the stomach is much more common in Great Britain than in the United States of America. This is an assertion difficult to prove or to disprove, for the mortality in this disease is small, and there are no statistics available of cases of illness which do not terminate fatally. The only reliable information would be obtained from noting the number of scars of ulcers which could be discovered at the autopsies of people dying of other complaints, and even this would be open to many sources of fallacy.

It is said, too, that gastric ulcer is much more common than duodenal ulcer, and this is undoubtedly the case. In London we get an enormous number of cases of gastric ulcer in young girls who are in domestic service. Why this should be so it is difficult to explain; they are comfortably housed, they are well fed, and, as a rule, they are not overworked. Many of them, it is true, are anemic, and anemia is, apparently, the starting point of the gastric trouble, but why their red corpuscles should undergo a diminution in number is equally inexplicable. In clerks and shopmen of the same age, and drawn from the same class of society, anemia is rare, and gastric ulcer is, practically, unknown.

Gastric ulcer is most common in girls between the ages of seventeen and twenty-six, whilst duodenal ulcer is the heritage of men between thirty and forty. What is it that determines the site of the peptic ulcer, and why in women should it be on one side of the pylorus, and in men on the other? Men, on the whole, take more in the way of stimulants than do women, but alcoholism is not a cause of duodenal ulcer. Men are tobacco smokers, but there is absolutely no proof that nicotine and its products are eliminated by the mucous membrane of the intestines. These circumstances are clearly not the clew to the mystery, and the explanation has yet to be found.

Of one thing I am certain, and that is that ulcer of the duodenum is far more common than is usually supposed. I say this, not only as the result of my own experience, but from comparison of notes with many physicians attached to our leading hospitals. The fact is that duodenal ulcer is frequently overlooked, for the symptoms are by no means characteristic. In the absence of hemoptysis, and this is by no means a constant symptom, there is often very little to point to this condition. There are the ordinary symptoms of dyspepsia, and, possibly, of peptic ulcer, and there may be some tenderness on the right of the abdomen, but this can hardly be regarded as conclusive evidence. Again, hematemesis may be produced by a variety of morbid conditions. It is not uncommon in cirrhosis of the liver, it may be secondary to cardiac mischief, and it may be the expression of some perverted state of the blood, such as that met with in that peculiar group of symptoms named after Banti. It is probable that an acute attack of hematemesis occurring in a man over forty is due to duodenal ulcer, but more than that we can not say.

The symptoms of duodenal ulcer are practically identical with those of gastric ulcer, as given in our text-books. It is true that in duodenal ulcer, melæna often appears when there is no vomiting of blood, but in other cases, just as in gastric ulcer, hematemesis is the first symptom to attract attention. The hemorrhage may be internal, and the first indication may be given by the onset of a grave condition of collapse. The symptoms of peptic ulcer, that is to say, those common to both these varieties of the disease, may be briefly summarized.

The pain is brought on by the ingestion of food, appearing from an hour to two hours after a meal; it continues until vomiting takes place, by which it is relieved, or it subsides as the food leaves the stomach. It is pressing, boring, tearing, or burning, and more severe than in any other gastric disorder. Sometimes there is pain in the back, between the dorsal and lumbar vertebra. The vomited matters may be the gastric contents, but, in some instances, blood is exuded in small quantities mixed with the contents of the stomach, the hemoglobin being converted into hematin by the acid gastric juice, so that the vomited matter has the turbid, blackish-brown appearance which is compared to coffee grounds. The blood may be extravasated in large quantity at once; that is, it is vomited, unmixed with gastric contents. The patient feels faint, has a sense of oppression in the epigastrium, and in a few minutes vomits the blood, which may amount to two, or three pints. It is dark from contact with the gastric juice, but if flowing from a large artery may retain its arterial brightness when evacuated. Some of the blood discharged into the stomach finds its way into the intestine, and is ultimately passed per rectum, in the form of black, treacly, or tarry motions; these may be passed long after the hematemesis has ceased. The vomiting of the blood may be fatal; often it ceases entirely, and may not be repeated for months or years. Anemia and weakness result from the loss of blood.

The continued pain, the defective assimilation of food from vomiting and the loss of blood impair the general condition, sooner or later. There is no fever, the tongue is clean, and the appetite is good. Constipation is frequent. Examination of the abdomen reveals nothing; there may be some hardness, or tenseness of the abdominal walls. Only in the case of old ulcers with much thickening, or adhesion to other organs, can a tumor be felt; or, if pyloric stenosis results, the dilated stomach may be recognized. Patients with hematemesis show a characteristic pallor, with hemic murmurs over the precordia.

The complications of duodenal ulcer are numerous. Amongst the most serious of these is hemorrhage, which may result from erosion of an artery or of a vein. The actual aperture, even when a big vessel is involved, may be small, so that at the autopsy it has to be looked for with care. The effects of a profuse attack of bleeding are serious, and the patient may pass into a critical condition, even in a few minutes.

Another complication is peritonitis, but as long as this is localized and confined to the base of the ulcer, it is not likely to

do much harm and probably will not spread.

When perforation takes place it is a much more serious matter. It may happen that the duodenum has become adherent to some other portion of the intestine, and if the lesion occurs at the point of union a "bimucous fistula" is formed, which is a happy solution of the difficulty. As a rule, however, perforation takes place into the general peritoneal cavity, and the symptoms are both grave and urgent. There is a sudden and severe pain in the abdomen, and the patient presents all the symptoms of collapse. The abdomen may be distended, but may be retracted from spasm of the muscles of the abdominal wall.

Tympanitis is common, and, as a rule, the liver dullness is absent. The temperature rises to 102° or 103° F., and the patient's face wears a look of intense anxiety. General peritonitis is set up, and, unless prompt surgical treatment is resorted to, the prospects of recovery are small. Sometimes, as a result of the perforation, a subphrenic abscess is formed; that is, there is a collection of pus in the hollow of the diaphragm. If the perforation is free there may be an exudation of gas and pus into the peritoneal cavity. The pus in the subphrenic abscess may perforate the diaphragm, giving rise to an empyema which may ultimately point in the groin, or in some far-distant part of the body, such as the popliteal space. When both gas and pus accumulate in the pleural cavity, we have a pyo-pneumothorax.

Another complication of peptic ulcer is *ulcus carcinomatosum;* that is, the simple ulcer takes on a malignant form. Such cases are rare and authorities tell us that since 1845 only thirty-two have been reported. The onset of this condition is usually indicated by a sudden rise in temperature. In a very short time constitutional symptoms supervene, and the patient shows signs of cachexia, with loss of flesh. These are the usual symptoms, indicating that some complication has arisen; but there may be others, the exact nature of which can only be inferred by clinical experience.

With regard to diagnosis, I am inclined to say that it is not possible, in every case, to distinguish between gastric and duodenal ulcer. I rely, however, chiefly on these points:

1. Duodenal ulcer occurs, chiefly, in men and in men of middle age.

2. The pain is experienced chiefly on the right of the duodenum.

3. The pain is delayed until some hours after food has been taken.

4. The vomited matter is alkaline, and contains bile and digested fibrin.

5. Melæna is more common than hematemesis.

I would add one word of warning, and that is not to mistake the gastric crises of locomotor ataxy for peptic ulcer.

The treatment of duodenal ulcer does not differ materially from that of gastric ulcer. In a bad case, especially if there is much hematemesis, or melæna, I should keep the patient strictly in bed, and feed by the rectum only, giving nutritive enemata, not exceeding four ounces every four hours, with a cleansing injection twice a day. The enemata should consist of milk or beef tea, with or without the addition of fifteen drops of tincture of opium. I should avoid stimulants. In many cases, nutrient suppositories, consisting of beef peptones, are useful. If the hemorrhage is abundant, the patient should be kept in a strictly recumbent position, and in a cool room. Astringents may be given, either by the mouth or rectum.

The most useful drug in these cases is bismuth, and the best form in which to give it is the carbonate. It is insoluble, is not changed in the stomach, and much of it passes up the intestine, where it forms a protective coating to the ulcer. To produce the effect, however, the drug must be given in very considerable doses, such as from one to three drachms three times a day.

Another remedy, at one time a favorite, but now comparatively rarely used, is oxalate of cerium. There is no evidence that it is absorbed, and any beneficial effects which may accrue from its use are probably due to a local protective action on the gastric mucous membrane.

Hydrocyanic acid, although used in gastritis and various neuralgic conditions of the stomach, is not likely to do any good in duodenal affections, as it clearly would not reach the site of the mischief. The

action of pepsin is confined pretty much to the stomach, and although of value in atonic dyspepsia, can not exert any beneficial influence on an ulcerated mucous membrane.

In conclusion, a word about the surgical treatment of peptic ulcers. It is the fashion, nowadays, to treat everything surgically. I have the greatest respect for the skill of our operating surgeons, but it must be admitted that their cases, sometimes from failure of antiseptics, and sometimes from apparently unavoidable causes, go wrong. I should never think of requisitioning the services of a surgeon in a case of gastric, or duodenal ulcer, except when a profuse hematemesis involved the life of the patient, and even then I should hesitate long before consenting to an operation. The opening is so small, the point of hemorrhage is often so difficult to detect, the danger of collapse is so great, that I prefer to trust to medical means in the great majority of cases, and not to sacrifice what small hope there may be of recovery. I quite admit that this view of the subject may not meet with universal acceptance, and that the triumphs of surgery are great. The responsibility of the physician is great, and I do not envy the position of the medical adviser who, perhaps, unaided and at a moment's notice, has to decide a question which is one of life or death to his patient.

Query From India.

BY LAL N. MANGAN, M. D.,
Raipur Ward, Vad-ni-pole.
Ahmedabad, India.

In your issue of June, 1907, you give a good cure for snake-bite, with alum. I request you to let me know if alum has any effect upon scorpion bite. If not, why so? Please give some good and effective treatment for scorpion bite, as scorpions abound here. Another question that I would like to have answered, Is a lizard a poisonous reptile? Can you supply any certain treatment for the plague?

[If any of our friends can give replies to above we would be pleased to hear from them.—ED.]

Absorbable Versus Non-Absorbable Suture Material When Sutures or Ligatures are to Be Buried.

BY CARLTON C. FREDERICK, A. M., M. SC., M. D.,
Clinical Professor of Gynecology in the University of Buffalo.
Buffalo, N. Y.

Before the time when catgut could be certainly and safely sterilized so as not to impair its tensile strength, it was absolutely necessary for the surgeon to have recourse to non-absorbable suture material, because the constitution of these was such that they could be sterilized by boiling. But since processes of various kinds have been devised whereby catgut can be rendered absolutely sterile, and at the same time not interfere with its tensile strength, there remains no reason why non-absorbable suture material should be buried, in preference to absorbable suture material. Catgut can also be chromicized, and at the same time so sterilized that it will endure in the tissues for any period of time that the surgeon may desire or require of a suture material. These facts being now positively proven, there seems to me no real reason why catgut, in some of its various preparations, is not preferable to silk, silkworm gut, silver wire, or any of the other many materials used.

It has been claimed by some that catgut is unreliable as a suture or ligature material because it can not be securely tied and depended upon. That depends entirely upon how the suture is tied and how short the ends are cut, after the knot is made. Catgut can not be tied as silk or any of the textile fibrous tissues are tied; it must be tied by a single knot at first, and then one double knot or two single knots, the ends of the suture being left at least one-half to three-quarter inches long. The writer has never seen a catgut ligature to untie or slip when so used.

Suture or ligature material is placed simply for the temporary stoppage of hemorrhage, or to approximate the parts that are sewed. Ligature material does not need to hold a vessel longer than six to eight days. Suture material does not need to remain *in situ* longer than two

to three weeks, therefore plain catgut may be used to tie vessels. Only in closure of abdominal wounds is it necessary to use chromicized gut.

To those who object to the use of catgut, those who have had an experience of years in its use can only say, in reply to their criticisms, that they do not know from a large enough experience how to handle catgut. It has been the writer's experience, at least two or three times, and sometimes oftener each year, to go on a hunting expedition at various points in the abdominal cavity for infected non-absorbable suture material which has been left by some surgeon of repute. Within the past month an abscess containing a silk ligature about the left fallopian tube was opened, this abscess had been draining periodically into the woman's bladder for a period of three years, and prior to this operation there had been removed through the posterior vaginal fornix two silk ligatures, and three had come out through the lower angle of the abdominal incision. This is not an unusual experience and observation of the writer, consequently he feels that silk, celluloid thread, silkworm gut, silver wire, etc., have no place as buried suture material in any part of the abdominal cavity, except in the gastro-intestinal tract. He does make exception to that part of the abdominal cavity, for in the gastro-intestinal canal silk and Pagenstecher thread may be used freely without any serious after-results, because the intestine will invariably throw the suture material into the lumen of the gut rather than into the peritoneal cavity, and it is eventually carried through the bowel with the feces and discharged, leaving no ill-results.

Catgut may be rendered absolutely sterile by the iodin method, by the dry heat sterilization, and other chemical processes. The author's preference is the process by immersion of the gut previously wound and tied upon glass spools in a three per cent solution of formaldehyde for a period of three hours for the smaller sizes, and four to six hours for the larger sizes, then washed in running water for from four to six hours. The catgut may be thrown into water raised to the boiling point, and kept at that heat for at least half an hour, then removed into sterile containers with ninety-five per cent alcohol and a little glycerin added thereto until ready for use.

If the surgeon desires that his catgut shall not only be aseptic, but also antiseptic, he may remove it from the plain alcohol and glycerin solution a month before its use and place in a solution of iodin in ninety-five per cent alcohol in the strength of one-half to one per cent. The gut will absorb the iodin, so that when he has placed it as a buried suture it will slowly give up its iodin and sterilize the suture tract, thus preventing the growth of colonies of bacteria in the dead, although still sterile, material.

If chromicized gut is desired, the gut can be placed in a solution of bichromate of potash or bichromate of soda, three grammes to one litre of water, to which is added twenty cubic centimeters each of carbolic acid and glycerin. In this the gut may be left for twenty-four hours, then thoroughly washed for twelve to twenty-four hours in running water and sterilized, as before described; thereby a gut is obtained which will remain in most tissues from two to three weeks before absorbing.

The author feels so strongly, as a result of his experience, both personally in his earlier surgical career and from those cases which he has seen where patients have been sufferers because of the use of non-absorbable suture and ligature material, that he feels that too much can not be said to induce the younger surgeon, early in his operative career, not to try silk or other materials in preference to catgut and kangaroo tendon.

61 Richmond Avenue.

Poison Oak or Ivy.

A California subscriber writes us that there are many cases of the above in his surrounding country, and asks that we request the readers of the BRIEF for articles on this subject, bringing out the ideas and treatment for the same. We hope that some one will oblige us with a contribution of this kind.

The Crying Need of Better Therapeutics in Brain and Cord Lesion.

BY AMBROSE C. STEWART, M. D.,
Professor of Neurology in the Westminster University Medical College.
Denver, Colo.

The profession stands appalled at its helplessness in the presence of most of the deeper pathologies of the brain and cord. Let us, for example, first consider with regard to the therapy of the chronic maladies. Whether they be membranous or periependymal.

From the allopathic standpoint we have iodide of potash in moderate doses. This in many cases offers us a valuable remedy if gastric disturbances do not arise, and if the case is not too severe, and the area involved is small, and the subject a good one. The cures, however, under the iodide of potash treatment are certainly not brilliant.

In the treatment of syphilitics I must say that I prefer the iodides to the mercurials. The mercurials, I believe, have a much narrower field in the spinal lesions of syphilitics than is usually supposed. Opium is sometimes used, but beyond its palliative effect little or nothing can be claimed for it, and it must be said with regard to all opiates that they are very apt to restrict dynamic resistance and render a cure more difficult.

Just what hope is held out by the use of ergot, or its field of action in deep lesions of the spine or brain I am unable to say; it has never appealed to me.

In silver nitrate we have a most valuable ally in not only staying the ravages of these diseases but in cutting short their course, and I believe in many instances the effect of silver nitrate in my practice may be said to have been absolutely curative. I use it in homeopathic potency.

The salicylates are valuable in some of our rheumatic cases, provided these cases are comparatively recent, and the destruction has not been too great.

As to the bromides: I ceased to prescribe them years ago, and candidly, I derive little comfort in contemplating the future of a case that presents even the milder manifestations of bromidism. Bromides certainly are undeserving the therapeutic fame once enjoyed. They will serve, however, as a short bridge to more rational therapeutic expedient.

In the acute lesions of the spine and brain I entertain serious doubts as to the efficaciousness of gold chloride.

Phosphorus is more extensively used among the old-school people than ever before, and, I think, with good reason. Its action is decidedly reconstructive in that class of cases in which it is indicated.

I am afraid of the use of strychnia where there is true pathology of the cord or brain unless we desire to create quick nerve stimulation and reaction. Its action is comparatively temporary.

Hyoscin can not be regarded as curative, but has a wide field as a palliative and nerve sedative. The homeopaths rely very largely upon five or six remedies. Aconite, where the indications are the swaying inco-ordinate movement; thirst, heat, shooting pains, involving the lower limbs. Anacardium, especially where there is pressure about the knees with a band about the waist, and the not infrequent *plug* symptom in the spine.

Belladonna presents the picture of the patient who has twitchings, distortion and spasms. He is apt to be wild and raving; there is paralysis of the sphincters, incontinence of the urine, and where the predominating symptoms are of a sensory character.

Zinc is the nerve tonic of the new school; sensation is not markedly effected. Toxicodendron, the rheumatic cases; there is tingling and decided disturbance of sensation.

Plumbum: Itching, drawing, shooting pains, resembling tabes, following the courses of the big nerves. Electricity in some form is nearly always applicable in these cases after the earlier symptoms have passed away, especially when wasting has set in. Galvanism over the site of the lesion, especially in inflammatory cases; faradism later on to nourish and stimulate. Of course, if the reflexes are very unstable we refrain from its use.

The treatment of these cases will depend very largely upon the source from which they arise. We must view them from the standpoint of tuberculosis, malaria, syphilis, rheumatism, typhoid fever.

In tabes can the anti-syphilitic remedies in general, be relied upon to even stay the disease? I firmly believe they can not be. If at all, they are most effective in the preataxic stage.

A few cases have been reported cured among the remedies given above, but we must consider that there are very often in these cases decided errors in diagnosis. The best authorities tell us that two years after the syphilitic symptoms have been clearly defined, the mercurials and iodides are of doubtful value. I believe that the mercurials are frequently decidedly harmful, the toxic action of this mineral upon the tissues that are already diseased can not be looked upon with complacency by the careful physician.

I fear the profession has not fully profited by the inquiry (Brauer's-Leipz, '97, and others) into the toxic action of the mercurials upon cornual and other nerve elements. Cautiously used, they have a curative range, but I should fear to assume the responsibility of saturating any patient with this permanent mineral poison.

The treatment of the old school has finally boiled itself down to "keep him quiet," "avoid all excitement." "Give a little silver nitrate, promise nothing." I would add, "avoid early morphinism." Nerve stretching, galvanism, faradism, and static positive spark make up the total.

The new-school man has a little the best of it here, perhaps, because he hews closer to the symptomatic lines, and hence gives more comfort to his patient. After all, the profession is to all intents and purposes in the position of the crew who have left the ship, and are standing by helplessly waiting for the final plunge beneath the waves.

What has been said of these conditions may be truthfully said of pretty nearly all of the deeper lesions of the brain and cord, and the efforts of the neurological world to-day should be bent untiringly and unswervingly to the discovery of effective therapeutic measures which would go hand in hand with the newer and better pathology of the brain and cord, constantly unfolding in response to the genius of the age.

Neuro-Deformities in Children.

BY JAMES W. COKENOWER, M. D.,

Professor of Orthopedic Surgery and Clinical Orthopedic Surgery in College of Medicine of Drake University.
Des Moines, Iowa.

It is generally conceded that nearly all deformities, especially in children, not traumatic or hereditary, are due directly or indirectly to some abnormal condition of the nervous system. This branch, like all other branches of medicine and surgery, bows with obedience to its *Alma Mater*, because we can not understand the anatomy, pathology, and histology of the nervous system unless we understand general medicine, and the laws of cell life and birth.

My experience as a general practitioner prompts me to admit that nothing is more important than the nervous system and its disorders, and yet there is nothing in medicine in which our knowledge is more deficient. In the investigation of even so simple an ailment as headache, the field of medicine must be well examined to know whether the real cause of the pain is a vicious, hereditary nephritis, lack of exercise, anemia, puberty, menopause, menstruation, masturbation, occupation, or one or more of the myriad of other influences or diseases, all of which it is necessary to know to cure a simple headache.

How much more then is it necessary for him who would successfully treat the nervous system, especially to that extent to obviate deformities produced by or through the nervous system, to know thoroughly not only the nervous system, but the entire human system, and everything that would hinder or augment its normal development. Unless we have such knowledge, we will still find ourselves treating apparent poliomyelitis or scorbutic rachitis for paralysis, torticollis for cervical adenitis, trismus for an erupting wisdom tooth, and the knee jerk for morbus coxarius. These being the deformities produced by abnormal changes in the nervous system. Ovarian deformities (if I may be pardoned mentioning the fact), which do not come under the scope of this paper, or any other in many in-

stances, would not occur if a better knowledge of the nervous system and its influence over each component part existed.

The remark once made by Prof. Jenner, that more mistakes are made by not seeing than by not knowing is not without a lesson, and helps to confirm the fact that more mistakes are made in diagnosis than in treatment. Next to the deformities produced by poliomyelitis or infantile paralysis are those produced by hysteria, which the consensus of modern writers on the subject has placed among the diseases of the nervous system, and which, by no means, is the most easily handled. I believe in the nervous being that a line of general treatment may be used that will lessen the chances of such deformities or mitigate against existing ones. For these the constitutional treatment must be looked after first, and the drugs used indicated by the specialization of the disease. Talipes, club-foot, wrist-drop, retro-lateral curvature of the spine, and, in fact, nearly all of the muscular deformities known to the orthopedic surgeon, may be produced by some nervous disease, and to undertake to cure the deformity by surgical means without first endeavoring to ascertain the real cause which produces the deformity, and treat same medicinally, would not be in keeping with the modern medical and surgical science of the day.

Mechano-Therapy in the Treatment of Tuberculosis.

BY OTTO JUETTNER, M. D., PH. D., F. R. M. S. (ENGL.), ETC.

Professor of Practice at the "Cincinnati Post-Graduate School of Physiological Therapeutics;" Author of "Modern Physio-Therapy," a Text-Book of Drugless Therapeutic Methods.
Cincinnati, Ohio.

Massage of the Chest.—In order to understand and appreciate the therapeutic value of massage it is proper to acquire the manual dexterity which alone enables us to form any opinion as to the possibilities of mechanical therapeutic methods. To manipulate the muscles of the chest wall means to increase their blood supply, to develop them, to render them stronger and more active. This, in and of itself, means more vigorous respiration, especially if the mobility of the thorax proper has been increased. These effects should be aimed at in all cases of lung consumption, especially during the early stages. The *modus operandi* is subject to variation, owing to peculiarities of individual cases. In a general way the following suggestions will be found applicable to most cases:

The patient being placed in the dorsal decubitus, the operator begins the manipulation over the costal border, gently picking up between his fingers a fold of skin and subcutaneous tissue, lifting it from the bony structures beneath and gently kneading it between his fingers. Most patients will be found to be "hide-bound," the soft tissues of the chest wall being very tense and hard to raise. Eventually, *i. e.*, after repeated sittings, the fold of the skin will come up with comparative ease. This manipulation requires all possible patience and gentleness. Lack of delicacy would be worse than worthless. Gradually the manipulation is extended over the whole chest. This form of massage may be followed by gentle stroking in a horizontal direction. Each sitting should last from fifteen to thirty minutes, to be repeated after twenty-four hours. Within a week or two the muscles of the chest will be less tense and probably a trifle fuller. At this juncture exercise of the thorax might be begun. The operator places his flat hand over the right or left side of the patient's chest, making firm and gradually increasing pressure. The result will be a partial immobilization of a portion of the chest. If the patient is told to breathe deeply the effect on the unengaged side of the chest will be more or less intense. The patient will expand the unengaged side of the chest more than he would without immobilization of the other side. The operator may alternately place his hand on one and the other side. He may vary the procedure by placing both hands on the lower portion of the thorax, over the last three ribs, thus forcing the patient to expand the upper portions of the chest vigorously. In this way the expansive

power of the chest can be increased considerably, rendering inhalation of fresh air a therapeutic factor of prime value. In applying these mechanical methods to individual cases, much depends upon the judgment and the individualizing faculty of the physician. With proper care and judgment an immeasurable amount of good may be derived from manipulations of this kind.

General Massage.—In many cases of massage, especially before much impairment of general health has taken place, the invigorating effect of massage adds much to the comfort of the patient. Considering its effect on the circulation and, indirectly, on the metabolic functions of the organism, it is especially indicated in those cases in which weakness and marked exhaustion after comparatively little exercise or exertion are characteristic symptoms. Massage in these cases takes the place of muscular exercise and, if judiciously administered, is a very serviceable substitute. It should be given every day or two and never be carried to the point of irritation. Deep *effleurage* along the lymphatics of the extremities does well in cases in which symptoms of autointoxication are conspicuous, *e. g.*, headache, muscular pains, fatigue, insomnia, etc. General massage in and of itself is often sufficient to relieve these symptoms. It frequently prevents night sweats. Superficial massage should be avoided on account of its irritating effect on the skin nerves. All massage movements in cases of this kind should be centripetal, with a view of depleting the venus and lymphatic vessels. If the tendency towards hemoptysis is well marked more than ordinary discretion should be exercised in the carrying out of any mechano-therapeutic measures.

Gymnastics of the Respiratory Apparatus.—The tubercle bacillus would give us little concern if the body of the consumptive patient did not offer a splendid soil for its growth and dissemination. The colonization of the tubercle bacillus on and in the tissues of the patient is preceded by a period of preparation during which the tissues gradually become a suitable habitat for the germ. The process of preparation begins with neglect of the lung function. Inasmuch as imperfect lung function may be conditioned by inherited bad quality of the body, its parts, tissues and fluids, it may be said that the process of preparation frequently begins in the preceding generation or still further back. A wretched physique, small, flat chest, poor blood and other evidences of physical inferiority may be the heritage of a human being in whom the sins of his fathers are thus being avenged. Scrofula, tertiary or inherited syphilis, rachitis, and many other conditions of bodily wretchedness are the punishment which nature metes out to those who sin against fundamental principles of hygiene. The offender may be an individual, a family, a tribe, a race. The sufferer may be another individual, another family, another tribe, another race. To save the species nature gradually destroys the part. This is the biology of tuberculosis. Tuberculosis is not inherited *per se*, but all the conditions favorable to its development are. The moment the individual is born, the struggle for existence begins. If the weapons of defense are absent, the doomed victim of a progenitor's misdeeds succumbs. The fittest survives. This phase of the subject is an hygienic and economic problem which should be solved now, so that the countless unborn in the bosom of the future may live. It is a problem that will never be solved unless man, in the aggregate, returns to first principles of hygiene. This would be the crowning effort of civilization in its most exalted sense.

The habitat of the tubercle bacillus is not always inherited. Sometimes it is acquired, or even assiduously cultivated. The surroundings, the habits, the occupation of an individual, may prepare a suitable soil. Lung function may be neglected, resulting in a corresponding atrophy, shrinkage or degeneration of the lung and its container, the bony framework. The result would be deficient oxygenation of the blood and a corresponding deterioration of the quality of the whole system. The diminution of the amount of oxygen assimilated by the lungs leads to a gradual lessening in the number and quality of the red-blood cells. Thus the

resisting power of the system is constantly waning. Alcoholism and other bad habits may add their share to the general collapse. The soil is ready for the crop of hungry scavengers that are being carried in with every breath. The battle for existence has begun.

In these cases of incipient phthisis the therapy should begin at the seat of the trouble. The lungs should be developed, the chest wall be made to expand, the organism should receive its physiological share of fresh, healthy blood. This can be accomplished by strict enforcement of the hygiene of respiration by a rational system of lung gymnastics. Patients must be taught to breathe, and must be given the proper kind of air for this purpose. This is the philosophy of chest gymnastics in a nutshell.

A consumptive must sleep, eat, play, and live in the open air. He must under no circumstances be confined where the supply of fresh air is limited. This is rational therapy for the individual and effective prophylaxis for those whose health he imperils by contact. It is admitted on all sides that the prevention of infection is even a greater problem than the treatment of the individual patient.

Light, air and water are the victorious phalanx that never loses a battle against pathogenic organisms. They are, as L. F. Flick, of Philadelphia, Pa., correctly remarks, the natural enemies of the tubercle bacillus. Sunlight and air kill it, and water dissolves it out of its *cache*, so that light and air may get at it. The bacillus comes out of a host wrapped up in broken-down tissue, which serves as a *cache*. When this broken-down tissue is deposited in a house it dries and hardens, and the bacilli inside remain alive for a long time. When it is deposited in the open, it is dissolved, or becomes disintegrated, and soon becomes devitalized. This is why an enclosure of some kind plays such an important role in the propagation of tuberculosis. In an enclosure sunlight, air and water can not get at the tuberculous matter and it remains vital; out of doors sunlight, air and water do get at it, and it soon becomes sterile. Houses of one kind and another are the ordinary means of spreading tuberculosis. The home is the most frequent means and the workshop the next. This is so because it takes prolonged intimate contact with a person, place, or thing that has been intensely contaminated with tuberculous matter to give rise to an implantation. The home and the workshop are the two places where environment of sufficient intensity of contamination and contact of long enough duration for implantation, most readily can exist. Probably three-fourths of all cases of tuberculosis which are conveyed from person to person are contracted in the workshop.

With the importance of air as a prophylactic agent firmly fixed in our minds we are prepared to understand the meaning of *inhalation* as a therapeutic measure. To exhort patients to breathe deeply while walking in the open air is excellent advice, but not of much practical value, because patients usually tire of monotonous and irksome exertion of this kind. We must, therefore, resort to some other means of enforcing deep inhalation. Therein lies the therapeutic value of all inhalation methods, irrespective of the agent used (oxygen, ozone, medicated vapors, etc.). The value lies largely in the act of inhalation, not so much in the character of the substance inhaled, unless it is the normal physiological lung food, namely, atmospheric oxygen.

The inhalation of manufactured oxygen out of an oxygen tank is being advocated by some. Theoretically speaking, the inhalation of oxygen ought to be the ideal treatment of tuberculosis. It ought to, as it were, supply the missing link in the chain of vital elements which are antagonistic to the bacillus and its development. More especially ought this to be the case when the expanding capacity of the lungs is being increased by breathing exercises or by thoracic gymnastics. Clinical experience does not confirm this optimism of the theoretical physiologist. The absorption of oxygen is regulated by the physiological oxygen-carrying capacity of the blood. This, again, is in direct proportion to the relative number and quality of red corpuscles. It is plain, therefore, that the forced introduction of oxygen into the air passages does not necessarily produce an equivalent oxygenation of the blood. In order to arrive at distinctly physiological, *i. e.*, curative ef-

fects from this method, oxygen must be not only inhaled, but absorbed. The blood of a consumptive is wretchedly poor in oxygen, because the elements which carry it are poor in quality and reduced in number. Hence, it is clear that the benefits of oxygen inhalation are, to a large extent, illusory in character. Then again, there is present in the organism that indefinable element which demands bulk or mass of physiological fuel, rather than concentration or extraction. The experiments which have been made with concentrated food elements as a pure unmixed substitute for food in bulk or mass, apply analogously to the problem of oxygen feeding. The disappointments which have followed these experiments have demonstrated that the human body and the test-tube of the physiologist are alike only in a provisional sense. The lungs demand bulk, not an extracted element. They crave for air, not for oxygen. Yet oxygen inhalation is not altogether valueless. Aside from being a potent psychic factor, it gives the chest a gymnastic training, and helps the patient to breathe deeply.

What has been said concerning oxygen inhalation holds good in regard to ozone inhalation. Ozone is an irritating gas, and, for this reason, is not very well borne by the air passages of the average consumptive. The popularity of the static machine has brought ozone prominently before the professional mind. Every static machine has its ozone-generating attachment, and the enthusiastic owner of such a machine never wearies of extolling the virtues of ozone. That the enthusiasm of these men has given rise to many an extravagant claim in its behalf, it is quite natural to suppose. The odor of the gas, not unlike chlorine gas, is disagreeable to many persons. Unless the gas is largely diluted with air, it is very irritating, and can hardly be borne by the average consumptive. If it is administered in a badly-ventilated room, the procedure is of questionable value. Ozone is in no way superior to oxygen as an inhalant, and possesses many disagreeable features which oxygen does not. After all, it is the mechanical act of deep respiration wherein lies the good of any inhalation method. The mechanical act of deep breathing does the good. The substance inhaled (and there are thousands recommended) is the psychic and persuasive factor. A record of chest expansion should be kept.

Deep breathing must be enforced, cost what it may. Niemeyer had an ingenious system of making his consumptive patients breathe deeply. He divided them into two classes. Each class was compelled to go out into the open air and walk slowly until they were tired. Then the members of the class were given a chance to lie down in invalid chairs or hammocks and rest. One of the number had to read aloud until another one took his place. Occasionally the whole class had to read, sing, whistle or play on wind or brass instruments. In this way the lungs were constantly active. The children were allowed to romp over the grounds at pleasure. Those that were too weak were allowed to sit in the open air and make soap bubbles with straws. No patient's lungs were allowed to remain idle. It makes no difference how inhalation is effected. The principal thing is to enforce it. There is a sanitarium in the Black Forest, in Germany, which—with due apology to the author of the Divine comedy—has a sign over the entrance to the grounds which reads thus: "Walk slowly and breathe deeply whoever enters here!" Sudden changes in the temperature of the inhaled air should be avoided, especially if the bronchial symptoms are well marked.

On another occasion I hope to discuss the value of other physical therapeutic agents in the treatment of consumption.

[Written for the MEDICAL BRIEF.]

Psychical Inhibition and Its Consequences.

BY R. W. SHUFELDT, M. D.,

Major, Medical Department United States Army (Retired); Member Medico-Legal Society, New York City, Etc., Etc.

New York City.

If we assume that psychical science is that science which has to do with all that pertains to mind and its attributes, both known and unknown, to life in its physiological sense, then all animal forms when

living offer the legitimate material for investigation of psychical phenomena on the part of the scientific psychist or psychologist. It would not only apply to man, but all the way down through the scale below him, to include the lowest types of animal forms endowed with life, and exhibiting mentality of any degree whatsoever. Many there are who include the study of the "human soul" in the domain of psychical research, but as there appears to be no evidence having any claim to reliability, up to the present time, of the existence of any such a thing as a "soul," human or otherwise, it must be understood that in discussing what is to be discussed here, only what is psychologically recognized as mind and life will be given consideration.

By life is meant simply corporeal existence in animals—vitality—and with the cessation of life the phenomena exhibited on the part of mind, in any individual instance, at once ceases with it. Mind involves volition, sensation, and the power of thought. It is the ego, and stands quite apart from any such a conception as an hypothetical soul, and much more distinctly from what some define as spirit. There are those who utterly confuse the matter of mind with what romancers define, since the dawn of history, as "soul" or "spirit." Some even conceive the soul of a person to be a substantial entity, retaining the body's general contour after death, and in that state has received all sorts of appellations by different peoples. It has further been contended that this soul, during life, possesses all the emotions, conditions, sensations and powers above attributed to mind, including the power of the will. In recent times it has been claimed that all animals below man, and even plants of all descriptions, possess a soul, which surely is absurd, though it can be easily demonstrated that all living organized beings possess mind and reason, and hence will power, in some degree or another. Further, it has been held, and is held by the legion of the superstitious to-day, that this so-called soul of animal, and even plant life, feels, thinks and wills after dissociation from the dead body—a state and a thing that, to the scientific mind, is quite inconceivable.

Will, in the living animal, means nothing more than the power of conscious, deliberate action, whether exerted in any way on the part of any portion of a healthy or an unhealthy body, under the direction of a sound or an unsound mind. When the action is involuntary, as when an animal flinches from any sudden danger, then such action becomes instinctive, and is not performed under the direction of what is here defined as will. Instinctive actions, however, may be simulated with greater or less fidelity, the same morphological portions of the body being brought into play to enact them. As an example, the difference may be seen in the case of a malingerer feigning an attack of epilepsy, as compared with the involuntary movements observed on the part of one undergoing the invasion of a genuine seizure of that disease. During life, in animals normally constituted, the will is under the control of the mind, and in all respects its servant where it is voluntarily exerted.

Now, in psychical or psychological operations, the mind may decree to perform a certain act or thing, and if the performance of such an act be perfectly possible, and the body of the animal, at the same time, be in all respects in a normal and healthy condition, then, if no hindrance of any kind whatever is interposed, through the exertion of the will, that particular act will be performed, and, in all probability, performed to the entire satisfaction of the animal willing it. There are all shades and degrees of such acts, and the nature of them is wellnigh infinite. Involuntary acts on the part of the body or any organ or portion of it, however, are in the matter of numerical comparison, almost immeasurably less in number or kind. Then there are the distinctly involuntary actions involved in the functions of many of the organs of the body, that are not under the control of the mind or the will, as, for example, the peristaltic action of the intestines and other organic structures. Others, to a greater or less degree, may be under the control of the will, psychologically directed, as, for example, the increase of the respiratory movements of the lungs; the deferment of the act of normal defecation or micturition, and similar func-

tional performances. These voluntary and involuntary acts shade into each other in all manner of ways, and in both healthy and unhealthy animals their study is of immense importance, while at the same time few subjects present a greater amount of interest in the matter of research and experimentation. In extremely rare instances we may even meet with subjects having an extraordinary control over the usual involuntary action of some of the organs or viscera of the body. Many years ago the writer had a woman under observation who possessed the power of exciting a diarrhea in herself by simply "giving her mind to it," and a male patient had the most remarkable mental control over the action of his heart, rendering, at will, its usual beatings almost inaudible to the ear of an expert examining it.

Now, it has long been known to physiologists that inhibition of reflex action pertains to certain organs of the body as a normal condition; as, for example, the inhibitory influence of the pneumogastric nerve over the heart's action. This restraining, or hindering, or repressing of the organ's usual action is effected in a reflex way from the higher nervous centers through the nerves of distribution to the organ thus inhibited. Inhibition of this nature may be designated as organic inhibition. As has just been pointed out, it may, in very rare cases, be induced or suspended through a mental operation by means of the will of the subject having such a power.

Psychical inhibition may be described as a checking or repressing of the operation of the mind or the will in any animal, and in some instances it may be associated, in a way, with organic inhibition. The checking or repressing of an involuntary yawn; as compared with the similar repression of one commenced through the voluntary effort of the mind, is an example of this.

Psychical inhibition may be exemplified in any representative of the animal kingdom, from the lowest to the highest forms. In all it may be exerted in an infinite number of ways, from the instant of birth until the death of the individual. Its primary effects and ultimate results or consequences vary in different species and races; in different temperaments, diseases and states of health; in the two sexes and at different ages, and at different times under different circumstances in different environments. Thus, it will be seen that the subject is a very large and far-reaching one.

A moment's reflection at the outstart is sufficient to convince one that psychical inhibition may operate in one of two ways. Let us take, as an example, an average boy of our own race, at the age of puberty. He is a child of intelligent parents, but, as in most families, sees in his antecedents, extending far back into the future, all manner of relatives, both male and female, who were represented by all kinds and classes of people. The natures and impulses of some of these may have been decidedly good, and they may have possessed minds and wills to live out those natures, both to their own credit and to the distinct advantage of every one with whom they were associated. On the other hand, some of this boy's ancestors may have been endowed with pronounced criminal instincts, and they, too, being of energetic casts of mind, lived lives that were a curse to themselves and disastrous to the community of which they were a part. Finally, others may have been mental weaklings of no use to themselves and simply a burden to all their friends and relatives of the times in which they lived.

Now, through inherited proclivities, this boy will, sooner or later, begin to develop what is in him, and, if he lives, evolve the kind of man he is to become, or may become—may become, for it will altogether depend upon what is brought to bear upon his mind and will as to whether his real nature asserts itself or not. If he possesses strong criminal instincts of any kind whatever, they may be so strong that no amount of influence brought to bear upon the natural bent of his mind and will can ever, at any time in his life, turn him into the narrow road of a virtuous and worthy life. Such influences may, and probably will, affect him in one way or another, but he remains a criminal nevertheless to the end of his existence.

Here is one kind of psychical inhibition wherein the deterrent effect of its force

fails. But there have been, and will be in the future, all grades of it, depending upon the nature of the individual and the character of the influence brought to bear upon him. In some instances the criminal instincts may be so weak in the boy, and the inhibitory influences brought to bear upon him so good and so long continued, that in time all that is bad in him is subordinated to such a degree that his life's career is rendered a thoroughly worthy one. Although extremely interesting in many cases, and perhaps important in others, we need not here consider the influence of psychical inhibition in the case of mental weaklings and sexual deviates. With respect to the former it were better had they never come into the world, and as to the latter the subject is too complicated an one to discuss in this place.

Our hypothetical boy, however, may possess a character just the reverse of the one depicted above, and instead of the criminal strain in his composition it may be one that will reach, in varying degrees, the most exalted standards for virtue, energy, talent and usefulness to his fellow men. Here, again, the restraining influences brought to bear upon his mental bent and will, may be, upon the whole, good or bad, weak or strong, of long or short duration, the results being just the opposite of these described in the case of the boy of depraved and criminal inclinations and character. Their full consideration would exemplify the second kind of psychical inhibition that may prevail with certain classes of individuals. In the matter of its operation psychical inhibition may be mutual, that is, be interoperative between any two persons; the sexes may be the same or they may not; the nature of the influence may be of a great many kinds and brought to bear upon the mind and will in an untold number of ways. It may be subtle, it may be brutal or gentle, insinuative or pronounced, weak or forceful, good, bad, or indifferent, and so on. Again, it may be brought to bear through the power of speech—the voice, or through the eyes and features, or through certain actions—behavior, or through all of these combined.

We may study this question of the restraining power of one mind and will upon another, and its consequences in all phases, grades, and classes in society, but perhaps nowhere to better advantage than we can among the married. When this is said, special reference is made to those of the Indo-European race who have entered upon the monogamic bond of wedlock, and who are living in close domestic relations with each other. Where such couples are mutually and harmoniously affined, no such thing as the ill-effects of psychical inhibition are to be observed, for the "incompatibility of temper," which is often another name for it, is not there to give rise to them. If each of such a pair are healthy in all respects, both mentally and physically, they simply grow as they should grow, their natures evolve as they should evolve, their home environment stands in evidence of all this, and the results of health, happiness, success and prosperity are almost invariably present in their domestic atmosphere.

It is only where the reverse of this is the case that the dire evils of psychical inhibition come in and become more and more evident as the life-spans of the pair are lived along, eventually terminating either in divorce, in insanity of one or the other, or both, wreckage of health and happiness, and a growth of surroundings which to call a home would be the very height of mockery. The aims, tastes and ambitions on both sides here may be of the best in the world, while they are not mutually compatible, and in their strife to adjust them, to subordinate or ignore them, consciously or unconsciously, the operations of the mind and the will, usually of both parties, is through an ever-present inhibition distorted in a thousand ways.

In the vast majority of instances the physician is called in sooner or later. If he chances to be of the right sort he will, in time, recognize the cause of the various physical troubles, the unhappy faces, and the atmosphere of restraint about the home. Should he not possess the necessary education, however, and other qualifications, he may treat the mental and physical troubles of this unhappy pair till the crack of doom and then effect no cures.

Through my own observation and in my own practice I have recognized no end of cases of this character, and the usual consequences consist in the development in the different types of individuals, of various manias, as dementia, or melancholia with suicidal intent; neuralgias, alcoholism, obscure maladies associated with the nerves and muscles, chronic gastritis of a low form, cardiac troubles, impotency (in the male), constipation, and sometimes a general warping of mental and physical development. I must believe that physicians will do well to bear all this in mind.

471 West One Hundred and Forty-Fifth Street.

[Written for the MEDICAL BRIEF.]

Methods of Ascertaining the Renal Function and Its Importance to Surgery.

BY L. W. BREMERMAN, A. M., M. D.,

Formerly Professor Genito-Urinary Surgery New York School Clinical Medicine; Visiting Surgeon Oak Park Hospital; Member American Urological Society; Member Chicago Medical Society.
Chicago, Ill.

Operative surgery upon the organs of the genito-urinary tract has advanced during the last half century so that operative procedure is carried out almost fearlessly, yet mortality sometimes occurs unexpectedly, due to failure of the renal function, causing a complete suppression of the urine. The subject of the renal function in its relation to surgery is of vast importance, and I will endeavor to portray the different methods of ascertaining the total functional activity of the kidneys, as well as the manner of estimating the function of one kidney.

When a nephrectomy is performed, the essential question is the efficiency of the other kidney, and if the operation is performed on any portion of the lower urinary tract, it is wise to ascertain, as far as possible, the renal activity. I will consider the methods of computing the adequacy of the other kidney in nephrectomy, for when one kidney is removed, the functional activity of the remaining organ should be known, for the disease may be of bilateral character, and the removal of one organ may bring such a strain upon the other kidney that it will cause a complete suppression of urine, with a fatal result.

The object of ascertaining the functional activity of the kidneys, is to learn whether or not the action of the kidneys is lowered to such an extent that an operation will almost invariably prove fatal. Ordinarily, the urine is examined chemically and microscopically in all surgical operations, but this does not always prove whether or not the renal activity is normal or is lowered.

Exploratory incision is not often done at present, due to the fact that the functional properties can not be reliably ascertained.

J. W. Thomson Walker, of London, has shown that exploratory operation of the kidney is inadequate for diagnosis even when the methylene blue test was used, for, on incising the kidney, although the blue color of the urine was strongly marked, he found that upon exposure to the air the blue color of the tissue could not be produced. He had hoped to be able to ascertain the extent of the fibrous changes in the renal substance by the variation of the stain, but as has already been said, no change of coloring was observed, nor did it occur when hydrogen peroxide was used. It is necessary, then, that other methods must be employed to enable the surgeon to know more or less definitely the functional activity of the kidneys.

We will first consider the subject of cryoscopy. The physiologist teaches that the kidneys separate from the blood, and excrete a fluid, the urine, differing in composition from the blood. It has been shown that the function of the kidney is osmotic, and that the osmotic pressure of the urine is greater than that of the blood, therefore the work of the kidney may be ascertained by measuring the osmotic pressure of these two fluids. By osmosis is understood the changing of relations between two chemical solutions of different concentrations, which have for their purpose the equalization of these differences of concentration.

It has been demonstrated that there is an increased concentration of the blood in diseases relative to the kidney, and that

with the increase of the osmotic concentration of the blood, there is a corresponding decrease of the osmotic pressure of the urine.

Kümell lays great stress upon cryoscopy. Prior to its systematic use in all cases, his mortality for nephrectomy was one in six cases, on account of the absence or insufficiency of the other kidney. Since its use he has not had a single mortality in one hundred and forty-eight cases where one kidney was removed.

Cryoscopy of the urine, I believe, to be entirely too uncertain in its results to be of much value, as there is a marked variation in the co-efficient or freezing point in samples of healthy urine; particularly is this so in urine drawn from the bladder.

Cryoscopical examination of the blood, where the freezing point is markedly constant around -0.56° C., that any marked deviation from this point will be indicative of renal inadequacy. Kümell claims that where the freezing point of the blood is lowered beyond -0.58° C., it shows bilateral kidney disease.

I am inclined rather to accept the views of others that when the freezing point varies between -0.60° C. and -0.65° C., that a diagnosis of the bilateral disease can be made. This procedure, combined with the cryoscopy of the urine drawn from the separate kidneys by means of the ureteral catheter, is of considerable value.

The determination of the freezing point of the fluid is usually made by the Beckmann apparatus, which consists of a thermometer marked off in one hundred divisions, each of which is sub-divided into one hundred parts. This thermometer is immersed into a glass cylinder in which the fluid to be examined must be stirred continually, with a rod of platinum. The glass cylinder with the thermometer and fluid is placed in a freezing mixture at a temperature of -4° C. The fluid is continually kept in motion by the platinum rod. There is an instant when the fluid congeals. As the liquid changes into solid state, heat is expelled, which causes the mercury to rise to a certain point, where it remains suspended for a short time. This is the freezing point of that fluid. The freezing point of distilled water must be ascertained by then subtracting the former from the latter; we attain a figure which shows how much lower a temperature the fluid freezes than distilled water.

In demonstrating the freezing point of blood, a sample of from twenty to fifty cubic centimeters of blood is taken with a hollow needle from the vein of the arm. This is collected in the glass cylinder, and is defibrinated by stirring with a platinum rod. The freezing point is then taken. The freezing point of distilled water should be taken at each examination, for the purpose of testing the thermometer. With a little experience this test may readily be made in thirty minutes.

Another important test is the phloridzin test, brought into prominence by Klemperer, who discovered that phloridzin glycosuria did not take place in cases of chronic nephritis, but to Mering we must give the credit of first discovering that injections of phloridzin causes a temporary glycosuria.

Archard and Delmere have demonstrated the fact that phloridzin glycosuria was dependent entirely upon the efficiency of the renal excretion, and that any deviation must be produced by an abnormal functional renal activity.

Kapsammer, after an experience covering two hundred cases, declares most positively that phloridzin glycosuria should make its appearance within from ten to fifteen minutes after the phloridzin has been injected into the tissues. A delay of thirty minutes speaks for the essential functional disturbance of both kidneys, and if delayed for forty-five minutes, a nephrectomy is contraindicated.

Kapsammer uses the following technique: He injects into the tissue .01 grm. of phloridzin, and five minutes after the injection he makes his first test of the urine for sugar. This is repeated every five minutes until the sugar makes its appearance, if at all Personally, I can not conceive how Kapsammer can make such a positive statement from the examination of urine taken from the bladder which has been excreted by both kidneys. I will demonstrate later how this test may be carried out to much better advantage by carefully testing the catheterized specimens from the separate kidneys.

The methylene blue test for determining the activity of the renal function depends for its value upon the following points:

The time of the beginning of the elimination.

The duration of the elimination.

The quantity of coloring matter eliminated.

The colorless derivity of methylene blue is chromogen, the test of which is to boil the urine with acetic acid, which changes the chromogen into methylene blue. Blue does not enter into the urine until about thirty minutes have transpired. In diseased kidneys the elimination does not begin sometimes until several hours after the injection, and in some cases it does not appear at all. The delay in appearance is entirely proportional to the extent of the pathological lesion occurring in the kidneys. There are many errors which may arise in this test, for disease of the lower part of the urinary tract may cause delay in the elimination. Obstruction in any part of the lower tract, such as stricture of the urethra, hypertrophy of the prostate, partial or complete ureteral obstruction, has a marked influence in delaying the elimination of the blue, hence errors may arise in diagnosticating the renal functions. In a healthy individual, the time for the total excretion of the blue is, as a rule, from about sixty to seventy-two hours. According to my own observations I have noticed blue in the urine for a week after it has been injected.

Beers, of New York, claims that the blue may be eliminated after many weeks or months in cases of pyelo-nephritis, in the shape of blue stained particles of pus. He further claims that this is absolutely diagnostic of pyelo-nephritis. The methylene blue is deposited in the parenchymatous abscesses, which rupture into the pelvis of the kidney, and thus the blue stained pus is eliminated.

Delay of the methylene blue is supposed to be diagnostic of kidney disease. To make this test more accurate, the quantitative estimation of the blue must be taken into consideration, for the total quantity of blue is decreased in elimination if the function of the kidneys is impaired.

The technique of the methylene blue test is as follows:

Fifteen minims of a five per cent solution of pure methylene blue is injected into the tissue. The injection is usually accompanied with considerable pain.

I might mention here Beer's method of diagnosticating partial or total ureteral obstruction by the indigo-carmin test, He injects, hypodermically, a sterile concentrated aqueous solution of indigo-carmin into the tissues, and by an examination with the cystoscope and urethral catheter, he is able to diagnosticate ureteral obstruction. I quote from Beer's article as follows:

"A diseased kidney may fail to excrete, or excrete very late, indigo-carmin, without the use of the ureteral catheter; one might be misled to diagnose complete ureteral obstruction in such case though the ureter be patent. Thus it is clear that one method does not exclude the other, and that both must be used together. The ureteral catheter will arouse our suspicion of obstruction, and the indigo-carmin will verify or dispel this."

I find that ureteral obstruction is comparatively a simple condition to diagnosticate by means of a ureteral catheter without the aid of the indigo-carmin test. This method might prove rather misleading, particularly if the kidney was pathologically affected.

The electric current has been used in this work to enable us to reach more definite conclusions as to the efficiency of the kidney function.

It is evident that aqueous solutions offer resistance to the passage of an electrical current, which varies according to their composition. An electrical current passing through the urine owes its conductivity to its mineral elements, and not to the organic constituents. So the conductivity is hindered or enhanced by an increase or diminution of the mineral contents. It has been claimed that very satisfactory results may be attained as to the renal function by this method. The same disadvantage may be recited as for some of the other methods, as so many extraneous conditions are liable to upset the general character of the urine.

In taking up the methods that are employed for ascertaining the function of

the second kidney where one is known to be diseased, depends entirely upon the knowledge of cystoscopic examination and technique, and the catheterizing cystoscope, for examination of the separate specimens of urine is essential for a diagnosis. A simple cystoscopic examination of the ureteral orifices may aid us materially in reaching a conclusion as to the function of the second kidney, and the extent of the pathological lesion in the diseased kidney.

Neuman has outlined the diagnostic value of the appearance of the ureteral orifices in a disease of the kidney in such a typical manner that I will give his classifications:

1. When one orifice is altered, and the other normal, the renal lesion is on the side of the abnormal ureter, and the character of the deformity of the orifice may indicate the nature of the renal lesion.

2. Active congestion and swelling of the mucous membrane in the neighborhood of the orifice, and along the line of the ureter, also swelling and pouting of the lips, denote acute irritation of the pelvis or parenchyma of the corresponding kidney.

3. A dilated orifice, the lips acutely congested, while the color of the bladder is little changed, denotes recent and acute inflammation or mechanical irritation in the corresponding pelvis.

4. A dilated orifice, the lips being thickened and only slightly rounded, the mucous membrane between the lips of a dark red color, while the mucous membrane of the bladder is deeply injected and pigmented, especially along the line of the ureter, denotes descending ureteritis with dilatation.

5. An elongated or dilated mouth with hyperemia of the lips indicates acute inflammation of the parenchyma or recent distention of the renal pelvis.

6. A punched-out orifice, marked by thickening of the lips, and induration and congestion of the surrounding mucous membrane, indicates a dilated ureter with ascending ureteritis, the infective process extending along the surface by continuity.

7. A pin-head opening on a well-defined ridge of deeply pigmented mucous membrane, indicates induration of the walls of the ureter from the ureteritis; the infective material being conveyed from the primary focus in the kidney or bladder, principally, through the lymphatic glands and channels.

8. Pin-head contraction of the mouth of the orifice, without other vesicle changes, denotes spasm induced by pressure of a rough calculus impacted in an irritated ureter.

9. Inflammation of the mouth, and thickening of the lips, with inflammatory changes limited to the mucous membrane immediately surrounding the ureteral orifice, denotes mechanical irritation of long standing.

10. Simple dilatation of the mouth, without much thickening of the lips, and with congestion limited to the orifice and neighboring parts, suggest mechanical irritation of recent origin.

To a certain extent, these rules as laid down by Neuman will give us certain facts regarding the condition of one or both kidneys, yet, they may be more or less erroneous in reaching a positive knowledge as to the functional activity of the organs. The statistics gathered from the literature regarding kidney lesion is of some value in ascertaining kidney disease, but, however, the statistics of different authorities vary to such a great extent that their value is exceedingly limited.

Morris has found that solitary kidney exists in about one in two thousand six hundred and fifty cases. Kelynack claims that malignant growths occur bilaterally, one in every ten cases.

Polycystic kidney occurs bilaterally, according to Israel, in four in four cases. Morris three in seven cases. Dickenson's collected cases, twenty-five in twenty-six. Calculus is bilateral in fifty per cent of cases collected by Legueu; 11.78 per cent of Küster's cases, and 25.3 per cent of Torré's cases. Pyelonephritis is bilateral in eighty-three per cent of cases, according to Weir, and tuberculous disease is bilateral in about fifty per cent of cases. The variation in the different statistics cause them to be of little value.

The indigo-carmin test suggested by Joseph is made by injecting four cc. of a four per cent solution of indigo-carmin into the tissues. Elimination begins after twenty minutes, reaching its height in

about thirty minutes, and is complete in about two hours. Examination of the ureteral orifices, and the characteristic appearance of the urine pouring forth, together with the depth of staining of the urine, will give some idea of the functional value of the two kidneys. Methylene blue may be used in place of indigocarmin with practically the same results.

Ureteral catheterization with a collection of the separate specimens of urine for the purpose of making the different tests already mentioned is, to my mind, more valuable than the examination of the urine drawn from the bladder. The quantity of urine passed by the catheter in a specified length of time can not be used as a standard owing to the fact that the excretion may be influenced by many conditions, such as diet, nervousness and climatic conditions.

The author has seen the excretion of the kidney stop entirely for many minutes while the other was excreting normally.

Albarran gives the following as a standard analysis of the urine collected from one kidney during an hour in a healthy individual: Quantity, fifty to sixty cubic centimeters freezing point -1.20° to -1.50° C. Urea twelve to seventeen grms. per liter. Sodium chloride, ten to twelve grms. per liter.

If two separate specimens of urine have been collected into sterilized test tubes, cryoscopic examination of these specimens will give considerable information regarding the difference of function between the two kidneys. The sympathetic connection between the two kidneys is particularly marked, and it must not be forgotten that the function of a healthy kidney may be more or less influenced by the diseased condition of the other kidney. The functional activity of the known kidney which is healthy, or nearly so, will be decided upon if the volume of the urine from this kidney is greater, and the freezing point shows a greater molecular content than the urine which is collected from the diseased kidney.

The methylene blue test may be performed in the same manner as given above, with the exception that after the injection of the methylene blue the ureters are catheterized, and the separate specimens of urine collected from each kidney. These are watched carefully from time to time as they drain, to show the presence of chromogen or blue. The chromogen should appear in the urine after about fifteen minutes, if the kidney is functionating normally, and the blue color should commence in about thirty minutes under the same conditions. If the elimination of the chromogen or blue is delayed, the loss of function of the kidney is proportionate directly to the time of the appearance. Examination of these separate specimens not only are of value in determining the function of the second kidney, if one is known to be diseased, but will give us an insight into the pathological condition of the diseased organ.

The phloridzin test may be carried out along the same lines, and the separate specimens examined every five minutes for the appearance of sugar. In a healthy kidney, the elimination should begin in about fifteen minutes, and if it is delayed for thirty minutes, there is a marked functional disturbance going on in the kidney, and if delayed for forty-five minutes, removal of the diseased kidney is contraindicated.

The catheterized specimen of urine from each kidney is important from a diagnostic standpoint, for by a careful microscopical examination of these specimens, the pathological lesion in one or both kidneys may be accurately diagnosticated, for Heitzmann has proven without a doubt that it is possible to differentiate the epithelial cells that come from the different portions of the genito-urinary tract. He is able to distinguish between pelvic epithelium and epithelium from convoluted or straight tubules. He also states that if there is pus in the urine, together with desquamated epithelial cells, the pus is coming from that portion of the tract that is desquamating the epithelium, so from a comparative microscopical examination between the diseased kidney and the other one will give us striking evidence as to whether or not that kidney is free from pathological lesion. If there are present pus and epithelial cells, the comparative relation between those found in the diseased side, and those found in the other will give us

a sure method of ascertaining the condition of both kidneys.

I believe if the microscope shows considerable number of pus cells and desquamated epithelial cells from the tubules of the supposed healthy kidney, that a nephrectomy is contraindicated, as the strain thrown upon the remaining kidney is liable to increase the inflammatory process, or to cause complete suppression of the urine, and death, due to uremia.

I have endeavored, as far as possible, to dwell briefly upon the different methods of ascertaining the functional activity of one or both kidneys, but I am of the opinion that no one method will give us sufficient information.

I think that all the methods should be carried out, particularly, upon the catheterized specimens from the separate kidney, and by comparing the different data developed from this examination, we can come to a positive diagnosis as to the relative function of the kidneys. For a quick examination, I believe that the phloridzin test of the catheterized specimens, together with a careful microscopical examination, with a study of the characteristic epithelial cells in each, will give sufficient evidence to base our opinion of the functional activity of the kidneys. If there is a marked deviation from the normal, the kidneys are functionally inactive, and if this should occur in a supposed healthy kidney, a nephrectomy of the diseased organ is contraindicated:

The determination of renal function is exceedingly important from the standpoint of surgery, not only on the genito-urinary tract, but to general surgery as well, for hardly a day goes by, that I do not hear of a death that occurs after a major surgical procedure due to the insufficiency of the kidneys.

I believe that if a more careful study of our cases in relation to the function of the kidneys were made, that mortality would be decreased, due to the fact that a surgical procedure would be contraindicated when the kidneys were proven to be functionally inadequate.

Hebotomy.

BY F. T. FORT, M. D.,

Professor of Practical Anatomy, Operative Surgery and Surgical Dressings; Surgeon to the Illinois Central Railroad.
Louisville, Ky.

This operation I saw for the first time in Berlin, and, so far as I know, it has not yet been introduced here. Hebotomy has been performed successfully by some of the most eminent surgeons in Berlin, who speak very highly of it. I had the pleasure of witnessing one operation, and heard a very interesting paper read upon the subject before the Anglo-American Medical Society, in which the author described six cases, all of which were successfully operated by this method.

Symphysiotomy is an operation consisting in the cutting through of the pubic symphysis, and allowing the bones to separate, thus increasing all the pelvic diameters.

Hebotomy is an operation for a like purpose, viz., increase of the pelvic diameters, but different from symphysiotomy, in that the bone is sawed or cut through, while in the older method the bones are separated by cutting through the cartilage.

There are several advantages claimed for hebotomy; first, perhaps, of these is the fact that there is less motility at the place of separation.

Second, a better union is obtained where the bone surfaces come into contact, and the reparative process is more active than where the cartilage alone is cut through.

Third, there is less likelihood of producing laceration of the bladder, urethra and soft parts, as the separation of the bone is slightly lateral to the median line.

The operation of hebotomy is performed by cutting down to the right or left, preferably the right, side of the symphysis. A full curved needle is introduced, threaded to carry a chain saw, encircling the pubic bone, and sawing from within outwards.

After the operation has been completed and the child delivered, the after-treat-

ment is very similar to that of symphysiotomy; that is, in the use of adhesive strips around the pelvis, and the closure of the small opening made for the introduction of the needle. The patient is kept in bed from three to four weeks.

In symphysiotomy, the general mortality is from eight to twelve per cent. The success attending the limited numbers of cases of hebotomy leads me to believe that its introduction will cause a further lessening of this mortality.

Septicemia.

BY R. J. BOYNTON, M. D.,

Instructor of Materia Medica, College of Physicians and Surgeons, Boston, Mass.
South Framingham, Mass.

In view of the gravity of the above condition and its frequent occurrence I believe many physicians will concur with me in the opinion that few pathological conditions offer greater opportunities for energetic treatment and brilliant results. So frequently the result of procrastination, on the part of the patient, in the care of a trivial wound, or of inexcusable omission of prophylaxis on the part of the medical attendant, that I feel we should put forth extra effort to correct this foreign element, which we may have inadvertently permitted to inflict our patient. The following are citations of two recent cases, typical of the results I obtain.

Case of Mrs. S., age thirty-eight; in good health, except for slight cystitis. Youngest child aged twelve. Family history good. Was called early June 7. Found patient delirious at times, severe headache; pulse, one hundred and twenty and weak; temperature, 104.6° F. Had several chills and stated she had been in this condition about twelve hours. Obtaining a negative history, I gave an antipyretic in five-grain doses, for headache, ordered cold sponge bathing of face and hands every hour, and left.

Was called back in the afternoon, and found patient as I had left her in the morning. This time I obtained the interesting admission that she had inserted a hard-rubber catheter into the uterus, and a little blood came. The only change I made was to give one-sixtieth of a grain of strychnine and fifteen-drop doses of fluid extract echinacea every three hours.

On the 8th I found temperature 100° F., pulse one hundred and eight, and patient begging to be relieved of liquid diet, and wanting to get up. On the 9th I found patient normal, but weak, and left her to care for herself, ordering medication continued for a few days.

Case of Mr. H., aged sixty; good health; previous history good. Had slight chronic eczema of the lower third of right leg, which he had scratched a great deal, but had not suffered from it other than the itching.

On July 10 I found the patient suffering from chill, muscular pains and headache. Temperature 104° F., plus one hundred and eight and weak. Found abrasion over the tibia, surrounded by inflamed zone, and whole lower leg swollen and red. Two red bands, an inch in width, reached from knee to hip, and the glands of the groin were swollen and painful. I first opened up the point of infection, which had become encrusted, and cleaned it thoroughly with phenol solution, then I applied ammonium sulphoichthyolate to the entire inflamed area.

Cold sponge bathing of face and hands until temperature reached 100° F.; strychnine, one-sixtieth grain, and fluid extract of echinacea in fifteen-drop doses every three hours, constituted the only internal medication. Ammonium sulpho-ichthyolate was applied twice daily. This case made a rapid recovery, going out doors on the 13th, but had a slight relapse as a result. The knee becoming swollen and painful, I ordered him to keep off his feet and continue treatment, which was completely successful by the 18th.

While the above citations made good recoveries, they are not selected cases. In all septic cases I have found echinacea of great value, and I believe that when elimination of school prejudice permits its general use it will be found one of the most valuable additions to our *materia medica*.

[Written for the MEDICAL BRIEF.]

Some Remarks on the Pathology of Epilepsy.

BY MARC RAY HUGHES, M. D.,

Professor of Mental and Nervous Diseases Barnes University (Medical Department); Professor of Criminal Anthropology and Forensic Medicine, Benton College of Law; Associate Editor "Alienist and Neurologist."
St. Louis, Mo.

Up to the present time the pathology of epilepsy has not been definitely determined. Theories and hypotheses have been advanced, and have come to us from various sources, and from the pens of different writers, but in summing up their observations we can derive but the partial conception of the pathological condition of the arterioles of the cerebral cortex, and a few other structural changes.

The fact that contraction of the cerebral arteriole takes place during seizures does not fathom in any sense of the word the entire pathology. Each successive stage has a separate and distinct one. Heretofore, no one has ever taken the trouble to scientifically work out, through observations of the different stages of epilepsy, the exact mental phenomena.

Among animals the most common type to suffer from epileptic conditions are cats, and they furnish us the best subjects upon which to base our conclusions. They exhibit all the symptoms in successive stages that a human under the same circumstances would. Of course, cats, or any other animals of that class, as a rule, take the ambulatory form, but not always, unless artificially produced. However, the initial pathological condition is the same in any form, namely, arteriole contraction, though to a greater or less degree, depending upon the severity and amount of area involvement.

To get at the foundation and fundamental principles of this obscure pathology, we must necessarily secure the brains of animals during a seizure, which is easily done, although a different brain is quite necessary for each successive step, to show separately and distinctly the different pathological changes that are brought about during this mental phenomenon throughout all stages of the disease, and the separate classifications of the same. For instance, in grand mal there is a great amount of fluid in the ventricles, and naturally more pressure and vaso-motor disturbance, hence a more severe seizure than in petit mal.

The essential feature *sui generis*, in the pathology of epilepsy, all other features being subsidiary or organically causal, is in the alternating state, irritation and paralysis of the vaso-motor mechanism of the brain and allied nervous system, but chiefly the brain, especially at the beginning of the attack.

Epilepsy itself is a functional vaso-motor disease, an alternating vaso-motor condition of transitory paresis or paralysis and irritation, the irritation causing contraction of the arteriole supply of the convulsive area involved, and the extreme ventricular dilations, caused by excess of cerebro-spinal fluid in them, producing the coma and comatose symptoms.

A trauma or a blood toxine (auto-toxine or chemical-like alcohol, camphor, absinthe, amon. carb., intra-venous injections, etc.), or a peripheral irritation, faradism and galvanism, intra or extra intestinal, tapeworm, lumbricoid fistula in ano, etc., causes first a paralyzing impression on the vaso-motor mechanism of the brain blood supply or on the heart (cardiac epilepsy), causing the excessive pouring out of the cerebro-spinal fluid into the peri-vascular spaces and ventricles of the brain.

The distended ventricles or perivascular spaces by pressure give rise to the precursory aura, visual, auditory, gustatory, and other sensory forms, according to the part first feeling the pressure before coma comes on from excessive pressure.

The excessive pressure with the coma or comatose states irritates the vaso-motor centers of the brain, causing arteriole contraction and spasm of psycho-motor centers, and of parapsychic centers of the gray cortex, causing psychical epileptic automatism (vertiginous epilepsy).

This arteriole contraction, the result of primary distention, and the excess of cerebro-spinal fluid in the ventricles, cause the shutting off of the excessive cerebro-spinal secretion, and the return of the brain to its normal state after a

period of more or less prolonged sleep, according to the degree of vaso-motor anemia induced, the absorption and redistribution of the excessive fluid of the ventricles beginning again with the arteriole contraction, which, after the ventricular distention, and in consequence of it, first took place.

The cause of the spasmodic paroxysm is also the cause of the removal of the first cause of the epileptic condition, viz., the vaso-motor paresis and consequent pouring out in excess of the interventricular and perivascular space fluid into their natural receptacles in the brain. Whatever condition of the organism may cause first a paresis or paralysis of the vaso-motor mechanism so as to permit excessive filling of the ventricles to the point of such degree of distention as will bring vaso-motor irritation of the cerebral arterioles, will develop an epileptic or other convulsion.

A trauma, a toxicity of the blood, a peripheral irritation apparently transmitted from the surface or from an internal organ will do the same (gastric, uterine, rectal, etc.). The recurrency which characterizes epilepsy is due to a peculiar morbid vaso-motor impressibility acquired by frequent repetitions of the cause, and by hereditary impressibility.

All the facts in pathology sustain this view, and need not be detailed. So far as my knowledge of the subject goes, no epileptic brain where death came in the status has ever been found with undistended ventricles, and all known causes of epilepsy have produced this state of brain. Inebriety, general paralysis, cephalic traumatism, toxic influence organically generated or taken from the animal, vegetable or mineral kingdom, and psychic influences have produced this state and phenomena of alternating conditions of the vaso-motor nervous system when even epilepsy or epeleptoid symptoms have resulted.

Petit mal is a lesser vaso-motor paresis, and lesser arteriole contraction involving the area of consciousness.

Jacksonian epilepsy is the same, involving one or a limited number of psycho-motor centers. In petit mal, the attack stops short of the psycho-motor region and profound unconsciousness.

The inherent or predisposing tendency of arteriole contraction found in grand mal is greatly lessened in petit mal, for the seizure falls short of the psycho-motor area, the inhibitory centers lose their identity, and partial or complete paresis ensues inversely as the profoundness of the seizure and vaso-motor constriction which inhibits the arteriole blood supply to the brain, thus ushering in the paroxysm, and the succeeding vaso-motor relaxation which finally suffuses the brain. The symptoms vary according to the difference in successive involvement of area. For instance, the difference in the aurae as the different centers are touched by the malady in the beginning of the attack, and so also do the symptoms of Jacksonian epilepsy appear differently, as the different centers are attacked by vaso-motor constriction.

Jacksonian epilepsy is a limited psycho-motor epilepsy without involvement of other psychic areas of the brain, so in order to show the pathological changes in tissue of the vaso-motor nerve centers, it has been necessary to select specimens that show the condition of each tissue change during a seizure throughout the whole category of epilepsy.

The coarse or gross pathological anatomy, as I have mentioned before, may be any lesion that would alter the vaso-motor movements, aneurismal, embolic, thromboid, or traumatic pressure.

In presenting this paper it has been my purpose to show that each epileptic stage has a distinct pathology, and the entire category or classification of epilepsy, including the psychical varieties, has one common pathology, or gross structural change, and that this structural change, whether idiopathic or organic, has to do largely with the movements of the centrifugal and centripetal mental forces as we find them in the psychical equivalence of epilepsy, dual consciousness, obliviousness, and allied states of mental eclampsia.

3872 Washington Avenue.

Correction.

In Dr. C. R. King's article on Pneumonia, page 722 of the September BRIEF, the last ingredient in the second prescription should read Simp. Syrup q. s. 1 *drachm* instead of 1 ounce.

[Written for the MEDICAL BRIEF.]

Our Leprological Science is not Always Exact.*

BY ALBERT S. ASHMEAD, M. D.,
New York City.

From time to time we read in the newspapers that leprosy is hereditary and not "catching." But the illustrative cases, in every instance so related, are found to be just the opposite—contagious, and not hereditary. What was thought to have been heredity was merely contagion occurring in the family.

There never was a child born with stigmata of leprosy. The youngest leper, to my knowledge, was two and one-half years old. It was infected ("contagioned") with leper germs, as it showed bacteriologically leprous contamination.

Zambaco Pacha, of Constantinople, a very eminent leprologist, but not on all occasions without error, has claimed to have seen several very young children "born leprous." The stigmata which he believed leprous were not, however, real leprous lesions; they were "dark-colored skin," and mere "general weakness." There was no evidence here of the presence of leprous germs. A child born of parents, both of whom were in the late stage of leprosy, is almost sure to be weakly and degenerate. In those cases of Zambaco Pacha's, the diagnosis of leprosy was thought by many leprologists to have been erroneous. These critics were all men of immense leprological learning, who had seen hundreds of children born to lepers. No one in Japan, where there are one hundred thousand lepers, ever saw a new-born babe a leper.

Most of the oddities of leprological science of which we read in the daily press, are created in the reportorial rooms, and relate to the etiology, easy curability, etc., of leprosy. Some of these may be inspired by other persons for sensational purposes. They are enough, at times, to throw real science into spasms.

For example, I may quote here what was printed not long ago by a prominent New York newspaper, a special dispatch from its correspondent in New Orleans. This enterprising journalist informed a too credulous world of a great change in public opinion in Louisiana, "since the careful study for a dozen years" in that State had resulted in a cure being found for leprosy. "Soon," says this worthy scientist, "there will be no lepers in Louisiana, when the last one of those now in the leper home shall have been discharged cured or has died."

But, pray, how many of Louisiana's lepers have been segregated? How many are scattered over the south and southwest parishes?

Exactly one hundred and one lepers were put in the asylum, while the balance of four hundred were known to be remaining in the whole State. Yet the Berlin Leper Conference has declared that isolation was necessary to eradicate the disease, "Every leper," said the Board of Secretaries of the Berlin Leper Conference, "is especially dangerous to his family and fellow-workers." "Cases of leprosy frequently appear in the higher social circles." "Leprosy is now acknowledged to be a contagious disease." "Every leper is a danger to his surroundings, the danger varying with the nature and extent of his relations therewith, and also with the sanitary conditions under which he lives."

"The treatment of leprosy has only had palliative results up to the present time.

* * *

"In view of the virtual incurability of leprosy, and considering the good results which have followed the adoption of legal measures of isolation in Norway, the Leprosy Conference, as a logical issue of the theory that the disease is contagious, has adopted the resolutions offered by Dr. Hansen and Dr. Besnier, of Norway and France."

Here follow the three well-known laws, recommending "obligatory notification, of observation and isolation, leaving it to the legal authorities, after consultation with the medical authorities, to take such

* I send you three photographs of two Japanese lepers, the one front and side views, although he looks to be quite old, is a mere boy, aged fourteen years. The other is a girl of eighteen years old. These are typical cases of Japan's leprosy, and no one could mistake them for any other disease. Whoever sees a face like one of these may be sure he is looking at a leper. As educators then, of the general practitioners, to whom THE MEDICAL BRIEF goes regularly, these pictures of genuine lepers may do duty to our American race if you will print them along with my article. The great trouble in this country is that many physicians do not know a leper when they see one, and some cure other diseases and really think they have cured leprosy.

measures as are applicable to the special social conditions of the districts."

Even if the "cure" referred to by the New Orleans correspondent of the New York paper should result in the closing of

the single asylum in Louisiana there would be many other foci of the germ still left uneradicated. Moreover, that very ordinary treatment of leprosy that has been so strangely glorified in the public press, on occcasion after occasion, and so boastingly called a cure for leprosy, is by no means at all times a cure. Those three lepers, who were discharged as cured, could by no means be so soon so surely known to be cured. For enough time has not even yet elapsed since their symptoms abated to positively determine this question. Tortoules Bey, of Cairo, Egypt, has waited six and seven years, and even then "hesitated" to shout "cured." For he knew that as soon as the same remedy is discontinued for a length of time, the disease returns.

Of course, spontaneous cure may result in some of strong vitality or endurance, as Hansen claims for so many Norwegian lepers, some of whom have come to the United States. And it is especially noted in every leper country that some rich families are apt to have a "recovered" leper living at home. But spontaneous cures of leprosy would not be enough to clean up a whole leper asylum, so that its doors might be forever shut.

Some cases might even be claimed to be cured and discharged as *cured*, which are not unquestioned lepers. It is very easy to make the mistake in diagnosing the disease. Only bacteriological examination of many secretions or tissues may determine the point. And the positive or negative analysis should be published before "cure of a leper" is shouted abroad. Those authorities in Louisiana seem to be too anxious to claim curability by the identical medicines commonly used in every asylum in epidemic leper countries. There is nothing in Louisiana's climate to warrant a belief that these well-known leprosy remedies could act any better there than in any place else on earth. And even if we should be able to obtain there the same or greater measure of palliation, or "cure," as has been claimed in

every country, from time to time, by those same drugs, being continuously used, would that alter things? Even Besnier and Tortoulis Bey, or Hansen, would never authorize their own legal authori-

ties to rely on them alone to eradicate from a whole people the scourge of leprosy.

A long period of discontinuance of the remedies alone will definitely test the claimed cure of leprosy. Four years must pass by without return of tuberculous symptoms after apparent cure of consumption, according to the schemata of the National Association for the Study and Prevention of Tuberculosis, before we can call it a case of cure. When two years only have elapsed, without recurrence of cough, we say it is "apparently cured." It is the same with leprosy. No

one can say the disease is cured even if four years have passed.

Leprosy in Louisiana will not "pass away," even if all the lepers in the leper home at White Castle are discharged cured by chaulmoogra oil, arsenic, strychnin and good nutrition.

The *Voice of Job*, a newspaper published by the thousands of lepers of Colombia, says that these same measures are not curative, only alleviative.

Even Besnier's case, presented to the International Dermatological Association at Paris, which was claimed to represent a cure after five years' administration of two hundred drops of chaulmoogra daily, was questioned as to its reliability by the eminent man who had examined it.

In Louisiana the cures have resulted where only a maximum dosage of fifty to one hundred drops daily were administered.

The Egyptian specialists gave as high as five hundred drops a day, and then hesitated to claim ability to cure leprosy. Yet in Louisiana they dismiss lepers as cured one year and seven months after being put on very modest dosage, and even five months after a last attack of leprotic fever, and while the "patches of pigmentation" of leprosy (the macules) are "still visible as level with the surrounding skin," and while the "wrinkling of the lepromas are not yet perfectly smoothed."

How dare physicians call this a cure? Moreover, a case of cure in one of "high social standing" needs especial caution in determining the question, to avoid criticism afterward.

In persons of "high social standing," in every country, leprosy is frequently given another name. Thus social ostracism is avoided.

Even if the other eight lepers in the Louisiana Lepers' Home, who, it is said, are "well on their way to recovery, as all active lesions of the disease have been arrested," and even if in these cases, as the report says, the only symptoms remaining are "the ghastly pigmentation, the white or bronze color of lepers, which will take some time to wear off," even if these eight should recover to the same degree as the three discharged ones, and are discharged also, will this help out the eradication of leprosy in Louisiana? Will it not rather increase leprosy by scattering the foci to other human groups? In heaven's name, are not all those symptoms stigmata of leprosy? *Quand l'ouveut se debarrasser, d'un cheval morveux en le trouve sain.*

Epidemic and endemic leprosy in Louisiana is a distinct menace, as administered by present methods, to the welfare of nine millions of negroes in our Southern States, a race peculiarly susceptible of leprous infection.

Our benevolent care of lepers also is sadly out of joint.

"When I visited the lepers in Louisiana," writes Father Conrardy, "I did not inquire much about the treatment followed by the lepers. It was my intention to go back and then attend to that.

"It seems they are divided into three categories, those who are expected to be cured, the doubtful cases, and those for whom there is no hope. If the chaulmoogra oil makes them sick, codliver oil is substituted. I don't think the patients take the medicine very regularly after each meal; the most of them take the medicines. However, I can not say much about that, as I visited the lepers but two days.

"I thought to have them showed to me —the three classes—and to be enabled to see them take the remedies, but, owing to circumstances, I did not see them a second time.

"The reason there are only fifty-two, instead of two hundred or more, in the asylum, is because the lepers are not looked after by the Board of Health—things in New Orleans do not run smoothly. Lepers are known to be at large there. No law obliges them to go to the leper homes. Many believe leprosy to be very contagious, but, practically, the public looks upon it as not contagious. For my part I believe it contagious, but not to a very great extent, rather the opposite.

"How are we to explain the fact that quite a number of men and women lived on Molokai, during my long and intimate service there, with the conjoint lepers, and have not contracted the disease? Those same persons, men and women, had the best chance of becoming lepers, to contract the disease, living together as husband and wife, and, to my knowledge, did not contract the disease.

"Now that Dr. Dyer gets or has an extensive practice as specialist for skin diseases it is readily understood, for three lepers got discharged as cured. I have not seen them.

"Dr. Goto claimed, when in Molokai for the Hawaiian Government, to have cured several lepers, but these, as far as I know, were never discharged. He also has a hospital in the city of Tokio itself for the lepers, where he had, when I visited Japan, in 1896, some thirty lepers. I do not know how many this gentleman claimed he had cured. His hospital in Japan was by far not as clean as the leper home in Louisiana.

"The lepers in San Francisco would be glad, I am sure, if they were given in charge of these eminent gentlemen. It would also cost much less, and the lepers would be better taken care of. In Louisiana the leper administration gives the sisters (nurses) board and only one hundred dollars per year each for clothes. In San Francisco the employes are paid from $60 to $100 per month, besides their board.

"It seems to me, then, that for both the lepers and the administration, Sisters of Mercy are the best nurses to be found. No other persons in the world will do so well for so little money, because they are animated by higher motives than mere pelf—devotion to humanity being their passion, their greatest ambition.

"We know the Government at Washington has appropriated $100,000 or $150,000 to build a hospital, and to run it—I guess —on Molokai, but I have not heard that they have started it yet.

"In the meantime a Massachusetts physician, who is there, is getting a good salary, but so far, we have heard nothing about his work. I expect to go to China in September, and may stop off at the island to see how much the leper settlement has improved since I was there. I may still pay another visit to the lepers in Louisiana, but this last is doubtful.

"The treatment in Louisiana requires good food to back up the medicines. This will be impossible for me to provide to the Chinese lepers of Canton. For this reason I did not show as much interest in the matter as it seems I ought to have done when in Louisiana.

"With me it is not so much a question of *quality*, concerning the Chinese lepers, as of *quantity*. Instead of receiving only *one hundred and fifty* lepers in my care, for each of whom I will have only three cents a day appropriation, I might receive *fifteen hundred*, or many more, if I could spend for each the three cents a day.

"But, in time, I hope to induce the Chinese Government to care for its lepers. Next year 'a good physician,' now in England, will join me in the work; and

still another, from Belgium, thinks seriously of going to China to help us care for the lepers. When able to keep four Sisters of Mercy, furnishing them with board and clothes, without salary, then we will be pretty well fixed to care for the poor Chinese lepers.

"If those two physicians, without salary but merely on God's mission bent, join me, I will establish a kind of medical school for young men and young women, to train them as nurses, not so much for the lepers as for the people outside. Then leprosy could be more often recognized." Here endeth the lesson of this holy man.

Let me add that, in my opinion, if some wealthy, charitably-inclined person would only direct his or her attention to this work, so immensely humanitarian and Christian, among the Chinese, Hindoos, Japanese, or other lepers of the whole world, much good might be done for the poor unfortunates, so many of whom today are the prey of man's lowest motives, or have no one to care for them. Such a person would be praised by all the earth, and in heaven.

A lot of money is spent for things which concern not the human race, which do not ameliorate it, nor elevate it. When there is still, and always will be, so much suffering and misery in the world, it seems to me and others, wholly disinterested in the matter, other than philanthropically, that not so much money should be spent for dead things, inanimate statues, paintings, and the like, or for self-glorification.

We have museums for so-called objects of art, dead things, while the objects of art, human beings, boys and girls, men and women, the masterpieces of God, are not looked after. For my part, a poor, tiny babe is worth all and more than all the old statues of the past and of the present, and I may add, of the future.

Our civilization, so-called, perverts the natural taste in human inclinations. Some deluded persons will pet a dog, but will care nothing for a wretched human being who, no matter who this may be, even if a poor neglected leper, is worth infinitely more than the animals, and all the valued pieces in all our museums. That wealthy people prize more highly, those inanimate things, than human beings, ought not to be true. Education should refine and develop sympathy and love for the wretched people of every race, not only white, but black and yellow.

Treatment of Typhoid Fever.

BY SAMUEL METHENY, M. D.,
Professor of Theory and Practice of Medicine in Lincoln Medical College.
Lincoln, Neb.

In a large hospital experience I have treated many cases of typhoid fever with invariable success. This has been accomplished by simple and direct medication, with careful attention to diet, sponging and proper antiseptics. Two popular remedies frequently employed in the management of typhoid fever—calomel and quinine—I do not use, believing that they are invariably contraindicated.

When we consider the condition of the intestinal tract, it follows that the eliminative treatment is the rational one. If there is septic material in the intestinal tract it must be cleared away. This can be done by means of the salines and by enemas. Rochelle and epsom salts are non-irritating, and if given in small doses clear the bowels without producing violent catharsis.

When the bowels have been cleansed they should not be filled up with foods, as sometimes happens. Some patients tolerate milk, and this, with beef broth, or similar liquid food, should constitute the entire dietary. If I were limited to one food for typhoid patients I would unhesitatingly recommend beef broth. This is best prepared by trimming the shreds of fat from good fresh beef, then cutting the lean beef into little cubes and placing same in a jar of hot water and allowing it to simmer. The juice is squeezed out, seasoned with salt and given to the patient every three hours.

Medical treatment will depend upon the condition of the patient. Antiseptics are governed by the conditions present. While I do not care much for febrifuges, if there is much cerebral hyperemia and high tension of the nervous system, gelsemium is indicated. If delirium is wild

and muttering, hyoscyamus. If there is extreme tympanitic condition, turpentine stupes should be employed.

The temperature of the patient can be kept under control by frequent sponging. Enemas, also, relieve the feverish condition and should be given daily in the evening when the temperature is going up. If necessary an enema can be given both morning and evening.

My typhoid patients are permitted all the cold water they care to drink, not ice water, but pure cold water.

If the patient is in an extremely septic condition, the carbolates are indicated. If the tongue is brown and teeth covered with sordes, echinacea would be the chief remedy. If the membranes of the throat are dark colored and there is discoloration of the fauces, I prescribe baptisia.

By keeping up this line of treatment, eliminative, cleansing the bowels with salines, giving an enema once or twice daily, and sponging freely while the temperature is high, giving the patient all the cold water he cares to drink, limiting diet to beef broth, using antiseptics when they are indicated, my patients recover early and delirium is an unusual symptom.

The Correction of Errors of Refraction as a Therapeutic Agent in the Treatment of Various Disorders of Childhood During School Life.

BY AARON BRAV, M. D.,

Ophthalmologist to the Southern Eye Clinic; Assistant to the Wills' Eye Hospital. Philadelphia, Pa.

The school system of our large cities, while not in a state of perfection, is as good as we possibly can expect it to be, considering the condition and circumstances with which the controlling force of our board of education is surrounded. The pedagogues, learned and well-meaning men and women, who give their time and attention to the various school problems in the interest of our children, are often hampered in their work by politicians who understand the nature of the child very little, and by councilmen who will much easier vote appropriations for the construction of boulevards or for the granting of franchises than for the increase of school facilities that will place the children in properly-ventilated, well-lighted and fire-proof buildings, in which they have to spend six hours daily of their young and unstable years, during which time their mental and physical substance are in a continuous active process of development. The solons of our cities, composed of laymen not well versed in the physiologic phenomenon of childhood that characterizes the vital process of repair and growth, are—from the point of view of medical science and its most important branch, hygiene, that deals with the prevention of various bodily and mental defects, through its system of sanitation—unable to thoroughly appreciate the needs of our children of to-day. They measure by the standard of their own childhood, and fail to, or can not, differentiate between the condition that existed fifty years ago and the one that surrounds us to-day.

The rapid progress made in the affairs of the world within the last half century has left its impress upon the rising generation that requires constant study, investigation, and a careful adjustment of the sphere in which our future citizens are raised, is not only desirable, but eminently essential. Unless we revert to the days of darkness, unless we are indifferent to the physical and mental well-being of our children, we can not do better than invest our time and energy in developing our school system on a purely scientific basis that will prove a haven of knowledge, with the least expense of physical energy. After all, the physical aspect in our education must not be neglected. A sound mind requires a healthy body. If we compare the school system of half a century ago, with its simple and few studies, with the complexed system and numerous branches of to-day, superficially, we shall arrive at erroneous conclusions, and claim that our children are overtaxed far beyond their power of understanding, and we may then, perhaps, agree with Dr. Hollopeter when he says that "our school system produces hardened men and women, many of whom sink to criminal-

ity." But a deeper study of the mental power of the children of the present day will reveal the fact that they keep pace with the world's progress, and they are more receptive to intellectual impressions than were their fathers. The child of to-day could find no interest in a curriculum in vogue fifty years ago; its mental horizon has been widened long before it enters the school, by external surroundings. The child to-day demands more, can grasp more and is more receptive to complex studies. The mentally backward and the intellectually delinquent child is, in most cases, physically deficient, and very often the sense of sight is responsible for the lack of power of concentration. The curriculum is not much at fault, nor is the method employed by the teachers to be severely condemned; the chief trouble is the failure of parents to acknowledge physical deficiencies in their children that will account for their intellectual dormancy. A physically normal constituted child should be able to stand the wear and tear of school life without any serious breakdown, and should be able to master approximately the subjects taught at school.

A small percentage, that are virtually deficient in their mental domain, whose intellectual powers are below par as a result of hereditary environment, must, of course, be excluded from this rather dogmatic statement. These children ought to be placed in special rooms, under the care of special teachers, as they will never keep up with their classmates, and it is, indeed, a moral obligation upon those in power to provide for these under-developed brains. But the majority of the so-called deficient children that can not keep up with the demands of the school, who fail to advance yearly, do not belong to this category; their mental power is not inherently below normal, but is inhibited by some physical abnormality that is remediable by therapeutic agents. It is for the physical healer to find this inhibiting cause and remove it. It is not enough to agree with Judge Sweeny, of Long Island City, in claiming that "the grinding monotony of school life makes criminals," for such assertion is not supported by sufficient evidence. The bulk of the children taken into consideration, a process of analysis will soon reveal the folly of such assertion. The majority of children bear school life well, pass their examination, and bring home good reports monthly, suffer very little physically, and do not turn criminals as a result of grinding monotony; it is rather the minority that constitute the backward and the deficient, and, of course, only a very small per cent of this minority virtually become criminals. It is not the grinding monotony that is responsible for even this small percentage of actual delinquents. A thorough examination will, in most cases, reveal a physical abnormality that is primarily the causal element in the production of these mentally deficient cases. Adenoids, nasal polypi, catarrhal conditions of the nose and throat; chronic otitis media, some trouble with the ethmoidal frontal and sphenoidal sinuses, rickets, etc., are potent factors in the development of disturbances of childhood, but, above all, it is the refractive state of the eyes that leads in the causation of various disturbances in childhood during the school period.

Every ophthalmologist of experience knows that many children who could not get along in school, who received bad reports, and failed to pass their examination, were simply hampered in their work because of a deficiency in their visual acuity which, while not apparent, could easily be revealed on careful examination. I often had the extreme satisfaction of knowing that the correction of an error of refraction had changed an apparently deficient, yet struggling child, into a bright, good, studious and successful pupil. But parents are not willing and strongly oppose the idea of glassing their children. Stupid and ignorant parents, and often even intelligent parents, will say, "Doctor, there is nothing the matter with my child's eyes," "My boy has very nice eyes," "My little girl shall not be dependent upon glasses." They can not see the relation of the eye to the nervous system, and fail to appreciate that the latent refractive condition of the eye overtaxes the child's nerve capacity, and bring about the physical and mental unbalance. Parents can often notice that their children are myopic, but are not capable of judging a latent hyperopic or astigmatic condi-

tion. As a matter of fact, however, most children suffering as a result of eye strain are not of the myopic, but of the hyperopic simple, compound or mixed astigmatic type. The medical school inspector, whose official duty is to protect the interests of these unfortunate sufferers, does not remedy the evil. As a rule, these inspectors are young physicians, who had little or no experience in the practice of ophthalmology, and, at best, a hurried examination, made with Snellen's test card, does not reveal a latent hyperopia or hyperopic astigmatism, so that we not infrequently find children with a three or four diopters of errors of refraction that have never been warned by the school inspector. Nor is it a rarity that parents should disregard even the oft-repeated warning of the inspector, and the children go on struggling along with the physical abnormality that retards their progress, making school life a heavy burden, which they are unable to bear, until the physical unbalance manifests itself in mental deficiency. A very important factor to consider in this connection is the baneful effect of the advertising refractionist. It is a conspicuous fact that children constitute a very small per cent of the office practice of the ophthalmologist, and a careful observation will reveal the fact that proportionally they are not found, to any large extent, in clinical and hospital practice. Far more often are they seen in the hands of the advertising optician, and I need not emphasize the fact that they are absolutely unable to refract correctly children without a cycloplegic. It is impossible for the optician to determine the precise error of refraction in children. They give glasses as a matter of course, and when the child is not benefited by them the parents become well-strengthened in their belief that they are not necessary. The child goes on suffering, struggling against a physical abnormality until the period of exhaustion manifests itself, and thus an apparent mentally deficient child soon becomes an acquired delinquent, too late to yield to any known method of treatment. Of late, these refractionists have taken advantage of the absence of laws regulating the practice of this ophthalmic branch of medicine. They are no longer to be found in the stores only selling glasses under the name of optician, but they ply their trade in private offices, with regular office hours, under the assumed title of doctor, and, of course, the unsophisticated can not differentiate them from the regular ophthalmologist. To them the sign doctor is sufficient evidence of a regular college diploma and State license. Thus the people are easily misled and the progress of ophthalmic therapeutics is retarded. The profession is largely responsible for this condition of affairs. There are, even to-day, medical men who do not think refraction to be a branch of medicine. As a matter of fact, they were not instructed in their respective schools on the subject, and many of them to-day send their patients to these advertising refractionists. The remedy is, of course, in the hands of the profession, and the ophthalmologic societies should try to remedy the evil as far as possible. Two methods suggest themselves to me, *i. e.*, the public press and proper legislation.

1. The public press, whatever may be said to the contrary, is a potent factor of education, and is always willing to enhance the interests of science. The newspapers may take no interest in factional fights, but their columns are always open for anything that concerns the interest of the public. Through their columns the public could be educated to know that the display of a big eye in the window does not constitute a college diploma, does not mean State license for the practice of ophthalmology. The public should be informed that these men are using the assumed title, doctor, under false pretenses, so as to ensnare the innocent public; that they are plying their trade at the expense of the public and to their detriment; that these assumed doctors know nothing of anatomy, physiology, pathology, physiologic optics; that they can not differentiate between weak eyes requiring glasses, and weak eyes requiring medical aid; that the proper function of the optician is to grind and adjust glasses, but not prescribe them. The press, I am sure, will open its columns, for the interest of humanity demands that these evils be eradicated.

2. The medical profession should request such legislation as will prevent this class of opticians, mostly ignorant for-

eigners, to use the title doctor unless so obtained from chartered, and by the State recognized, college. This is not class legislation; it is simply a law that will prohibit the abuse of the title, doctor, which some people use as a cover to defraud the public. With these evils remedied through the press and State legislation, the public would soon be educated to the fact that suffering children require the attention of experienced men. The interest of humanity, the interest of the profession, demands that these evils be remedied.

School children are subject to various disorders during school life as a result of eye strain. Headaches, dizziness, nausea, vomiting, choreic form movements, general debility, eventually resulting in anemia, irritability and nervousness, culminating in neurasthenia and hysteria, mental deficiencies, etc., are disorders attributable directly, in a vast majority of cases, to an uncorrected error of refraction which taxes the nervous system of the child beyond its reserve force. The family physician who, as a rule, is first consulted in these cases, should bear these simple facts in mind, and advise a careful adjustment of any error of refraction, not by a refractionist, but by a competent ophthalmologist, and he will save many children from the evil consequence of eye strain, which careless observers attribute to the grinding monotony of school life.

917 Spruce Street.

THE diagnosis of children's diseases can be gauged by the nature of the expression or cry. Thus, the cry of croup is hoarse, brassy and metallic, with a crowing inspiration; in cerebral disease, such as hydrocephalus, it is short, sharp, shrill and solitary; marasmus and tubercular peritonitis, by moaning and wailing; obstinate and long-continued crying indicates earache or a prick of a pin; pleuritic conditions are indicated by louder and shriller cries on moving the child, or effort of coughing; intestinal ailments by wriggling and writhing before defecation. The cry, as an indication, grows weaker as the loss of power wanes. Sometimes loud screaming tells of renal gravel. The *kind* of cry in the infant should be considered in making a diagnosis.

[Written for the MEDICAL BRIEF.]

The Medical Service in the Ohio National Guard.

BY H. H. SNIVELY, A. M., M. D.,
Lecturer in Obstetrics at Starling, Ohio, Medical College; Major and Surgeon Commanding Ambulance Company, Section No. 2, Ohio National Guard.
Columbus, Ohio.

There is a prevalent idea among the great mass of people, especially those who have given little attention to the subject, that in the event of war the United States could mobilize a large and effective army very quickly. It is no doubt true that there is sufficient patriotism, and whatever else it may be, to induce a large enlistment should such a need exist. It is just as true, however, that any large body of men thus hurriedly assembled would not be effective as an army until it had been carefully trained for some time, and during this time the burden would fall especially heavy upon the medical and sanitary organizations, and any mistakes of omission or commission would be paid for in suffering and death. In order to meet such conditions, Ohio, since 1898, has given considerable attention to the medical department of her National Guard.

This organization follows as closely as possible that of the United States Army, and consists at present of surgeons, assistant surgeons and enlisted men. There is one chief surgeon, viz., Lieutenant-Colonel E. C. Brush, of Zanesville, Ohio; fifteen surgeons with rank of major; thirteen assistant surgeons with rank of captain; twelve assistant surgeons with rank of First Lieutenant; one hundred and eighty-two enlisted men, of whom four are first class sergeants. These first class sergeants correspond to the hospital stewards of a few years ago.

These medical officers are assigned to regiments, troops of cavalry, batteries, signal corps, engineers, etc. Each regiment is entitled to a major-surgeon, a captain assistant surgeon, and first lieutenant and assistant surgeon; each troop, battery, etc., to a medical officer.

There are four sections of enlisted men in the State. Hospital Section No. 1, at Cincinnati, under command of Major

Hall; Ambulance Company, Section 1, at Toledo, under command of Major Ralph Stewart; Hospital Section, No. 2, Zanesville, under Major Drake; Ambulance Company, Section No. 2, Columbus, under Major H. H. Snively, commanding.

The State has now equipped each medical officer with an orderly pouch, which contains aromatic spirits of ammonia, six bandages, a pocket case, chloroform, catheters, diagnosis tags and pencil, four first-aid packets, sublimated gauze, jack knife, catgut and silk ligatures, common and safety pins, adhesive plaster, rubber bandage, scissors, splints, wire gauze in roll, hypodermic syringe, and vials of hypodermic tablets.

A surgical case, which is called a "field operating case," contains scalpels, scissors (straight and curved), probe, director, etc., and an "emergency case," which contains among other things, antiseptic tablets, bismuth subnitrate, caffein citrate, camphor and opium, compound cathartic, chloral hydrate, tincture of digitalis, calomel, ipecacuanha and opium, morphine sulphate, potassium bromide, quinine sulph., soda bicarbonate, soda bicarb. and mentha pip., soda salicylate, etc. A small set of instruments, hypodermic syringe and tablets, clinical thermometers, etc.

In addition, each section of hospital and ambulance company has equipment for a field hospital, in which equipment are chests: the so-called "Medical and Surgical Detached Service," "Medical Chests," and "Surgical Chests." The "Surgical Chest" in a brass-bound oaken chest, with padlock, in a canvas cover and hinged crate. This contains a very complete assortment of instruments and material for surgical work. The medical chests contain medicines and dressings, and the "Medical and Surgical Detached Service Chests" contain medicines, dressings, an instrument case, chloroform, etc.

For the equipment of a field hospital there are provided five units of bedding and clothing, and ten units of folding field furniture, commode chests, boxes of surgical dressings and hospital mess chests. A tent unit of bedding and clothing contains sufficient equipment for one hospital tent for six patients, or, in an emergency, for nine patients. It contains nine bed sacks, nine gray blankets, six rubber blankets, nine pillow sacks, one folding stool, six convalescent suits, six bath towels, and six hand towels.

The tent unit of folding field furniture contains one chair, six cots, six pairs mosquito bar frames, six spreaders for same.

The miscellaneous chests contain lanterns, folding chairs, folding tables, basins, buckets, brooms, etc., and are for the use of small detachments of hospital corps men when sent to small bodies of troops on duty at riots, or in case of emergency.

In Ohio, as in Illinois and Massachusetts, the hospital corps men and ambulance company men are enlisted in companies. The maximum for the Hospital Company section is fifty-one, and for the Ambulance Company section, sixty-nine. It is the aim to enlist in these company sections men of a high order of intelligence and morality, and they are given a carefully graded course of instruction, which includes anatomy, physiology, hygiene, bandaging, nursing, cooking for the sick, transportation of sick and wounded, care of emergency cases, establishing hospitals, keeping of records, and preparation of reports.

A high standard of professional ability is insured by a rigid examination of medical officers before they are given their commissions. However, these medical officers serving for the first time with troops in the field find the medicines and equipment provided for them, as outlined above, to be quite different from those which they have been accustomed to use, and for a time they are at somewhat of a loss to know what to do. This difficulty passes away when they have had an opportunity to become acquainted with the prescribed therapeutic agents. Again, there is a certain amount of work to be done in preparing the reports and keeping records. This is a bugbear to an officer who has had no experience in such work. He should at least know how to prepare papers, and how to instruct his non-commissioned officers in this art.

There can be no doubt about the wisdom of keeping such a training school for medical officers and men.

In case of hostilities, a considerable number of medical officers who have been trained in field work would insure against needless loss of time and life.

Certainly a medical man who is patriotic enough to give of his time and strength to preparing in peace for efficient service in time of war, is deserving of the greatest praise.

1368 North High Street.

[Written for the MEDICAL BRIEF.]

Medical Thoughts, Facts, Fads and Fancies.

BY JAMES S. SPRAGUE, M. D., C. M., ETC.,

Examiner Materia Medica and Pharmacology College Physicians and Surgeons; Ex-Examiner Medical Jurisprudence Trinity University; Author Medical Ethics and Cognate Subjects (Ideals in Medicine. In press). Stirling, Ontario, Canada.

The above is the title of many, yet not similar, contributions I have given, very frequently, to several medical journals, as it gives me the opportunity of the expression of thought in reference to many and divers medical interests that present themselves as worthy; in fact, essential to be presented for the adoption, criticism, or even rejection, by those among us who have professional honor, and who are in love with our profession, and are necessarily jealous when the fair and time-honored name or interest of medicine is in any way, or in any sense, insulted. This *furor scribendi* for nearly thirty-seven years has occupied most pleasurably my leisure moments, and it is gratifying to call to remembrance many instances of approval given me by those whose hands I can never touch, for death has claimed them, and by those so remote that only by chance we could meet. Such recompense has been, and is the only reward I have asked and expect, and gratifying it is that there is evidence—abundant evidence afforded to me that my labors, pleasant in themselves, are bearing fruit as regards recognition by those who behold with disgust said fearful ruin to our profession, the condition of our profession's blind adoption of purely non-ethical preparations.

Easy Marks, we have been termed, and no better or more appropriate designation could be given, and yet we have, or are supposed to have, the cultured discernment and scholarship of a judge—even of the highest courts—scientific knowledge demanded by no other scientist, skill such as no artisan or artist has in his dreams; fortitude, resolution, perception, sympathy, the heart within and the God overhead, recognitions and beliefs; altruism that no priest or minister exercises; and yet, with these heaven-born virtues blush, and, better still, daily called in exercise, with very little murmurings or signs of discontent—you, my brother, are called an easy mark. Such I am, and since my graduation, in 1869, I have been an auxiliary in the ranks, and it is in a manner consoling to think, while writing this brief paper, that every other brother, if not each brother, is a standard bearer, and, as regards his business or financial interests, he has the qualifications and history and belongings, not developed since his first decennial period, as regards age. The life history of those who, in the ranks, have stood shoulder to shoulder with me, fully indorse my statements, and when I recollect incidents connected with my long medical life, some are with no pleasure preserved, but I console myself with the thought, "That it is not all of death to die, nor all of life to live," and I lament that others with the most brilliant prospects, strengthened by the best training of our schools, are entering the field, and, after a few decades in practice, their histories will be of those who have fought the good fight in medicine.

However, there are decidedly pleasurable reminiscences of very early medical practice in the State of Iowa, during which I was closely associated with congenial and fraternal spirits, whose many virtues and excellences of character and personality I recall, and I bring to memory the lines of Crosby when I think of each one, long since departed:

> But to live—every day to live out
> All the truth that he dreamt.
> While his friends set his conduct with doubt
> And the world with contempt.
> Was it thus that he plodded ahead.
> Never turning aside?
> Then we'll talk of the life he lived—
> Never mind how he died.

Before me, with your compliments, and letter requesting me to present this paper,

there is present in the list of frequent contributors to THE MEDICAL BRIEF for 1903, the photogravure of our—dear to me, and dear to all who love our profession—need I name it? Such is that of Dr. Ben. H. Brodnax, Brodnax, La., an humble village doctor, who never, in his many contributions, mentioned or indorsed a quack preparation, but urged all of us to adhere to well-established and well-known and official remedies. That he was, although living remote from the crowd, so, fortunately, not influenced by the banal literature of our medical journal advertisements, is, indeed, a mystery, but, judging from the correspondence I had with him during several years, one could easily find out he was not an easy mark for the fakir advertiser. I may here state that no writer for the medical journals has left a better record, and his influence will be lasting for the honor of medicine. However, he died poor. Had he been associated with others who claim *professor* in their titles, and had added LL. D. or Ph. D.—cheaply earned or purchased—would his honest labors have been more appreciated? No! We country doctors swore by what Dr. Brodnax wrote, and although dead, he speaketh in no uncertain words to the effect that official drugs are all that is necessary to us, provided, we well know their full and therapeutic actions.

If there is a name worth placing in the New York Hall of Fame, that name is the name of Ben. H. Brodnax, M. D., Brodnax, La. Need I say that the name of Cyrus Edson, M. D., is equally worthy of so honored a place?

These men I honor, for they never indorsed a patent dope.

My Iowa State Board of Medical license hangs on my walls, and the name of the President of the State Board is thereon inscribed, but when I behold before me this testimonial, named in a proprietary booklet, I consider the *easy marks* are not yet all dead, and I reflect that the greatest enemies our profession has are those of its own household.

Are the labors of N. S. Davis, M. D., LL. D., the founder of the American Medical Association, as regards the study of ethics, as related to medicine, been so little studied and held up so poorly to our profession, that our greatest enemies, quacks and quack medicine compounders, are asking us to certify to the merits of their worthless mixtures, announced in medical journals? Certainly, he who styles himself M. D. is deficient in the most elementary studies of *materia medica* and pharmacy who buys and recommends a dollar-an-ounce mixture—whose composition the ordinary druggist knows—that can be equalled for less than one-fourth of the money outlay. Yes, we are easy marks, for while we are engaged in the higher studies our enemies, the hangers-on to our profession, are actually undermining the temple of medicine, and are even inviting us, the innocents, to assist, and, strange to say, they obey the call, and even there are volunteers. Are you all innocent, readers? If you are an easy mark, or have been an easy mark, take a few moments for self-study; anyway, do not disgrace yourself and medicine, for there are too many who have done so, and have spilled much ink in the act. If this paper appear, I promise to present to the honest readers of this journal further indorsement of my views, fully believing in this, that "united we stand, divided we fall." That every M. D. should know his medicines and their components, as well as their therapeutical actions, and that to recommend a quack, or unknown compound, is decidedly unprofessional and contrary to the principles and teachings of ethics in medicine.

T. A. Daly, of Philadelphia, gives a beautiful sketch of the relationship of priest and doctor:

Padre Domineec McCann
He ees great beeg Irishman.
He ees growla when he speak
  Like he gona go for you
  Jus' for busta you in two.
My, he talk so rough, so quick.
  You weel wisha you could be
  Som'where elsa w'en you see
    Padre Domineec.

Padre Domineec McCann
Stop at dees peanutta stan'
W'en my leetle boy ees seeck:
  Talk so rough he make me cry.
  Say ees besta boy should die
So he go to heaven queeck;
  He ees speak so cold to me
  Nevva more I wantsa see
    Padre Domineec.

Den gran' Doctor com'. Ees queer.
When I ask who sand heem here.

He jus' smile an' weel no speak
Only justa for to say:
"You no gotta cent to pay,
I gon' feex dees boy dat's seek."
Oh, beeg hearta man an' true,
I am gettin' on to you,
Padre Domineec McCann.

The greatest enemies, Oliver Wendell Holmes says, we have, are old women and preachers, when the indorsement of patent medicines are considered, and I may add, charms and various incantations. However, the above poem illustrates that there are exceptions, and noble ones. If every minister, instead of recommending a patent medicine to his disciple or parishioner, would direct him to the doctors, we M. D.'s would respect these "guides of faithful souls" much more than is the custom among us.

[Written for the MEDICAL BRIEF.]

Senility.

BY W. E. PUTNAM, M. D.,
Ex-Surgeon-General of Vermont.
Bennington, Vt.

The period of development, that of middle life, and that of physical decay, constitute the three great epochs of human life.

Under the first division is included the whole time from birth, up to about the twenty-fifth year, during which the vegetative organs and those of the lower animal life are consolidating. The central nervous system is more slow in reaching its highest development, and the brain, especially, is many years later in acquiring its maximum of organic consistency and functional power.

The middle period of life, between about the twenty-fifth and forty-fifth year, is the time that the individual is subjected to the greatest pressure from external causes. The industrial classes are absorbed in the struggle for maintaining themselves and their families; the rich and idle are immersed in dissipation, or haunted by the mental disgust it excites. At the same time, the women are going through the exhausting process of child-bearing, and are either surrounded with the cares and duties of a poor household, or equally pressed with anxiety to attain positions for themselves and their children in fashionable life, or they are idle and heart-weary, or forced to an unnatural celibacy. Frequently, they are both idle and anxious.

The period of decline may be said to commence when the first indications of distinct physical decay manifest themselves, and when a new set of vital conditions come into force. There are not, however, any sharp lines of demarcation between the epochs thus sketched; the one insensibly growing into its successor.

Although the activity of the growth of the organs in childhood and youth offers a striking contrast to their decline in old age, there is, notwithstanding, a resemblance in the diseases of the two extremes of life, like the "tints of the rising and setting sun." Infantile convulsions and senile convulsions, infantile diarrhea and senile diarrhea, infantile eczema and senile eczema, uric acid deposits in childhood and the same in old age, may be adduced as illustrations of the resemblance of the diseases affecting the two extremes of life. In the early period, the constitution has not acquired its vigor; in the closing, it is losing it.

To the mere worldling, old age is repulsive; but when life has been spent wisely, errors corrected, the heart disciplined, and the intellectual and moral powers are in the ascendant, old age presents a spectacle happily described as "a crown of glory." A human being who, after fulfilling all the duties of life, is still living in a "green old age," whose eye is not dim, nor his natural force abated, though ripened for the future, may well command our admiration and veneration.

The decay of nature is *gradual*, and does not affect all the structures of the body equally at the same period; it also begins in some at a comparatively early, and in others not until a considerably advanced period of life. The following are illustrations of the changes attendant upon old age, and they exercise an important influence in accelerating that final one which is the common lot of humanity.

As age advances and senile changes gradually take place, the mental faculties partake of the general deterioration. That the mind retains its vigor and clearness of perception, while the body undergoes decay, is a poetic fiction; the brain shares

inevitably in the physical disorganizations to which the aged are subject. The various forms of man's decay are gradual and progressive. Death may take place suddenly from some form of heart lesion, apoplexy, rupture of an aneurism, etc., but it is only the termination, not the disease, that is sudden. For years before the fatal issue the organ was undergoing degeneration of structure.

The climatic conditions of winter are highly favorable for the discovery of all kinds of weaknesses and tendencies to organic disease, especially of the brain, heart, blood vessels, kidneys and liver. Facts on a large scale prove that defects in these organs manifest themselves most frequently and severely in cold weather. The whole constitution is lowered by the conditions of winter, and, to an extent, devitalized.

Medicine can only exercise an indirect power over these conditions, by prescribing such remedial or preventive measures as artificial heat, clothing, food, etc., to forestall, if possible, the effects of cold, and to counteract any of the organic changes that are sure to occur.

In alluding to the decay of nature, I would refer rather to the vital decay of individuals, than to the mere lapse of years; vital conditions can not always "be measured by number of years." It is well known that some people at fifty, or even earlier, are, in this respect, older and more shattered in constitution than others who have attained the age of seventy or upwards.

Our present manner of life, business haste and anxieties, tend to induce premature decay. Probably, as the result of improved sanitary measures, of a more correct and general recognition of the laws of health, the attainment of a vigorous old age without the premature feebleness and decay hitherto so generally observed, will be more common.

Treatment of the Aged.—There are many ailments peculiar to the approach of old age, which require special medical treatment, or the application of particular measures, in which the timely use of appropriate remedies, and the prompt employment of judicious means, are often rewarded in seeing the flickering flame rekindled, and valuable life considerably prolonged. I will touch upon only two or three points.

Food.—Food should be of much less solid form than during the vigor of adult life. Just as nature provides fluid food during infancy, before the teeth appear, so the loss of teeth, a common attendant upon old age, necessitates a return to a form of food that requires little, or no mastication. Inattention to this point is, I believe, a fruitful cause of much of the indigestion, weakness, and suffering of the aged.

Frequently, artificial teeth can not be tolerated, and the only path of safety lies in the adoption of an almost exclusive fluid diet. Some vigorous old people, who can wear comfortably artificial teeth, seem to thrive upon a more generous diet, in which solids form a part.

Rest is essential to the health and safety of the fragile frame of the aged. The sports and exercises of youth, or the exertions of maturer age, would fracture the bones, rupture the tendonous portions of the muscles, or occasion a blood vessel to give way; hence the folly of old people trying to emulate the stunts of the younger generation.

To the aged, long-continued exerise and too little rest are highly unfavorable, the reparative processes being only slowly performed. Fortunately, the activities and athletic exercises of youth become distasteful to old persons, and the burdens of mid-day life are transferred to the succeeding generation, and they now seek and enjoy a condition of quiet and repose necessary to their present well being.

Warmth.—In the winter season, when sudden changes of temperature are frequent, provision should be made for preventing the ingress of the cold early morning air, and for maintaining a suitable temperature in the bedroom through the whole night. The temperature of the sleeping apartment should be 60° to 62° F. It, no doubt, often happens that the lonely encounter with death takes place in the stillness of the hour before sunrise from a sudden access of cold air, which the extreme feebleness of old age could not resist or endure

As before stated, cold seriously affects the aged, and it is a fact which excites frequent observation, that soon after the

setting in of severely cold weather, the obituaries in the public press of persons in advanced life become unusually numerous.

That the coldest portion of the twenty-four hours, as a rule, and also the period of minimum vitality, is just before daybreak, is a fact full of warning to the aged, and to the feeble generally. How often has it been observed that the setting in of grave, or immediately fatal symptoms, has coincided with this daily recurrence of cold. When nature, refreshed by sleep, is summoning new energies in the young and robust to meet the exigencies of the coming day, the aged and infirm succumb in the greatest numbers to a depression which has been too deep and too prolonged to admit of any rallying. This fact gives force to my recommendation of striving to keep the bedrooms of old people at an even temperature, to neutralize, as far as possible, the consequences of this low temperature wave.

It is often advisable for the aged to take nourishment during the night, to tide him over the period of greatest exhaustion. Persons in health may be able to take sufficient food at a time for ten or twelve hours, but such a practice would be out of the question with the old, or the invalid.

In regard to medicines, I will offer no definite suggestions. The selection of remedies must be determined strictly according to the symptoms the patient may present, modified by any idiosyncrasy of constitution. They are, however, often of the greatest value.

124 South Street.

[Written for the MEDICAL BRIEF.]

Acron, the Chief of the Empiricists.

BY BROSE HORNE, M. D.,
Late Indiana State Prison Physician.
Gas City, Indiana.

All non-conformists will be interested in the life of the ancient physician, Acron. In his day the Pythagorean Society was the ruling class. We all admire a man who stands out boldly for what he thinks is truth, even if by so doing he is persecuted by those in power. In all ages we have persons whom, possibly, history neglects to speak about, that have manifested wonderful powers in assisting progress. This ancient physician, Acron, *was not* a member of the Pythagorean Society, but at the same time was more successful than any of the physicians of his day. Acron was made of the "proper stuff." He refused to be bound by any organization, creed, or ism. *He was a non-conformist.* All great men are non-conformists. The soul of things protests against being bound down to this or that theory. "Away with your theory! Let me cure my patient!" say all men, from Acron down to the modern non-conformist. Acron, the blessed, was a child of nature. He obtained his knowledge by *observation* and *experience.* He lived with the *plants of wild nature,* ever ready to learn lessons from the birds of the air, or the trees of the woods. We are interested in Acron because he is the father of true empiricism. The first to advocate the cause of a man without a school. He was able to defend himself against all of his rivals, and stood shoulders above the Pythagoreans, Empedocles, Alconœon, and all. This ancient anti-philosopher had the bravery and honesty to refuse to accept—and even combat—every species of physiological theory. He insisted upon *pure experience* only. None of his rivals knew where he obtained his knowledge, although they admitted that the man had a superior education. They were aware that he did not obtain it from Pythagoras, so all they did know was that he was able to meet them and hold his own. He was even acknowledged to be a master in his art by his rivals. Acron was the product and follower of the art of instructive therapeutics. His mind was ever looking for the particular diseased condition, irrespective of the name, so his remedies could meet the condition and correct it. Let us honor the chief of the true empiricists—he who would dare challenge the philosophy of his age. Although history gives this man very little, if any, notice, still a few fragments of his work have been handed down to us. Acron, speak to this century, and let your words thunder through all eternity: "I reject every species of physiological theory, and insist upon the value of pure experience only."

This man was a true empiricist, not an empiricist that treated named diseases. You speak of your Cullen, or your Hahnneman, your Hippocrates—why Acron is as far superior in principle, as Love is from Hate. At this man's door you can not place prejudice, schemes, dishonesty, trickery, false doctrines, murder and lies. No! He was a non-conformist, fighting for truth with honest weapons. His faith has been kept alive all these years by the shedding of blood by the poor, but righteous minority. If a reformer has ever lived he owes his existence to Acron, the one who survived and flourished about five hundred years before the birth of Christ. A success in practice, a success in life. The honest man, Acron of Agrigentum, who believed in doing unto others as one would have others do unto them. A man who dared assert that what he believed to be truth, to fight for it, even if all the organizations, laws and customs of the day were against him. Acron cured people with remedies, while the Pythagoreans—or predominant school—was quarreling over theories, and endeavoring to form a monopoly. Philosophy and dreaming were their habits and life, and practice, with results for good, were his.

Acron is dead. Long live Acron!

[Written for the MEDICAL BRIEF.]

Memorial on Medical Language Presented for Consideration to the Rectoribus Magnificis of All German Universities Convening in Marburg, July 31, 1907.

BY DR. ACHILLES ROSE,

Adjunct Professor of Medicine at the New York Post-Graduate Medical School.
New York City.

(Continued from page 691.)

In discussing the motion, the following observations were made: In recent times physicians of Western Europe have introduced new names into medical science, in order to designate new conceptions resulting from new discoveries and inventions. The greater part of these designations is taken from the Greek language, but most of them are incorrectly constructed, are incorrectly chosen. The Medical Society of Athens therefore desires to assist to the best of its ability in the establishment of a classic Greek medical nomenclature, which should serve as a guide to those men of science who avail themselves principally of the Greek language for scientific expressions. To carry this object into effect, it is proposed to collect all those irregular terms which have been introduced into medical literature, and to replace the same by classic Greek appellations. Such a compilation of corrected expressions, once definitely approved, will check the confusion which has existed and continues to exist in medical onomatology.

The first word mentioned as an example was phagocyt, which by some is called phagocyttosis, by others phagocytarosis, and by others still cyttarophagia. In such cases the committee will select the one best suited to express the intended meaning, so that in future it may be uniformly used by all authors. The authors who are at present perplexed as to which of the various denominations to use, will thereby be greatly relieved.

It will be seen that this discussion confined itself to the formation of new words for new conceptions. This is intelligible by the fact that the corruption of old-established Greek words occurs only in the medical literature of foreign countries.

In order to show how far this corruption really goes, I may be permitted to cite a few drastic examples from the German and English medical literature.

Abarthrosis, hermaphrodite for anarthria.

Abdominohysterectomy, likewise a hybrid for laparohysterotomy, Ἐκτομή means castration, and this is not modern, but ancient Greek, besides, the preposition *ex* can not be placed in the middle of a word. (Excision means ἀποτομή, but τομή may also be taken to signify amongst others excision.)

Abdominoscopy, a hybrid for laparoscopy.

Abepithymia is supposed to mean paralysis of the solar plexus. Grammatically correct, it would be anepithymia, but the term is not sufficiently distinctive, and therefore unscientific.

Abrachia is supposed to mean absence of the arms, but means in reality absence of rocks. The arm means *βραχίων, ονος*. The correct expression would be abrachionia or lipobrachionia (from *λείπω*). *βράχος*, rock, does not exist in any school dictionary, but is nevertheless good old Greek.

Acephalaemia defies explanation.

Acne is a word which does not exist in any language outside of medical slang; the Greeks call that particular affection acmai.

Acromicria is incorrect, likewise acromegaly, chiromegaly, splenomegaly. The correct terms would be mikakria, megalakria, or megakria, megalochiria, etc.

Actinogram is ungrammatical, the Greek word is *ἀκτινογράφημα*.

Aktinomykosis is ungrammatical, it should be actinomyketosis (*μύκος μύκητος*).

Akyeteria, recte akyteria (*ἄκυτος*).

Akystonervia is hybrid, and without meaning.

Adenektomia, adenektopia, doubly wrong.

Adenia, adenopathy, adenosis, are superfluous. Adenitis means affection or inflammation of the gland or glands.

Adnexitis is, similarly to appendicitis, to discard as puerile corruption.

Adynamia and asthenia are by no means synonymous, although they are frequently used so. In antiquity already asthenia was understood to mean illness, corresponding to our word infirmity.

Albuminometer instead of leukomatometer.

Amyatrophia and also amystrophia should be called myatrophia.

Anaemia is unscientific whenever oligaemia is intended.

Appendicitis. This barbaric word is significant for the puerile manner in which new words are formed, and does not constitute an honor to medical literature. Perityphlitis, as the affection of the vermiform appendix was called by our grandfathers, is an excellent, anatomically correct designation. The words ekphyaditis, epityphlitis, skolekoiditis, which non-Greeks have concocted with the aid of the school dictionary, are unscientific.

Arthropathy is superfluous, arthritis being the suitable Greek description of articular affections.

Asystolia is incorrect, if it is intended to speak of dyssystolia.

Atonia means absolutely nothing else but relaxation; it does not mean weakness or insufficiency, as some authors will have it.

Autodigestion is hybrid (analogously to automobile, which is called, in Greece, correctly autokineton). Autodigestion should be autopepsia.

Blepharoptosis should be blepharoptosia. (The grammatical rules about the terminations is and ia in compound words do not seem to be known to our nomenclators, as they use haphazard one or the other.)

Brachialgia, recte brachionalgia.

Bronchiectasia is ungrammatical and ugly.

Bronchorrhoea, judging by the word, the bronchus would run away.

Cavernitis. A word formation such as this makes the impression of being the work of a schoolboy or a jester. The correct word would be serangitis; similarly: Cellulitis instead of kyttaritis; here also belongs—

Cerebritis, instead of enkephalitis.

Chlorosis, recte chloriasis.

Cholecystitis and cholelithiasis are incorrect; they should be cholocystitis and chololithiasis. The adjective choledochus is correct.

Chthonophagia. It is surprising that such a word should have been formed so difficult of pronunciation, when the classic designations geotragia and geophagia exist.

Claustrophilia and claustrophobia are hybrid. The Greeks have the words philokleisia and kleisiophobia.

Conjunctivitis. Berlin lexicographers have complained of this hermaphrodism, regretting their inability to find a true Greek appellation. Their Helenophobia seems to prevent them, however, from consulting a latter-day Greek book, in which they would have found epipephykitis.

Corneoblepharon, recte Keratoblepharon.

Deferentitis, Greek spermatodochitis.

Dermatonosis is superfluous, because dermatitis is all-sufficient.

Diplakusis, recte diplakousia.

Duodenitis, recte dodekadaktylitis or dodekadaktylonitis.

Dysarthrosis, recte dysarthrosia.

Dysthyreosis, recte dysthyredeosia.

Ektasia, recte ektasis.

Epikia is supposed to mean house-disease, but really means colony.

Epoöphorectomia. German scientists assert that ovary means oophoron in Greek, although in Greece this word designates an animal that lays and hatches eggs, analogously to the words leophoron (signifying traffic road, avenue), and nekrophoron (hearse). The ovary means ootheke (egg store). It is possible that this word does not occur in classical literature, because the ovary was not mentioned or described there, but oophoron is the classical word for ovipar. I am somewhat explicit on this point, because I have had difficulties to offer the explanation.

Ovariotomy is oothekotomy, oophorectomy is a conglomeration of barbarisms.

Folliculitis, recte thylakitis.

Gastroectasia, recte gastro-ektasis..

Gastrectomy, recte gastrotomy.

Gastroenteropathy is simply gastro-enteritis.

Gastrohelioma is unnecessarily long; gastrelioma is sufficient.

Gastromegaly, recte megagastria.

Gastroptosis, recte gastroptosia.

Gastrorrhoea, literally the stomach or abdomen running away; what is meant is chylorrhoea.

Gastrosucorrhoea. Greek at both ends, Latin in the middle. Our grandfathers called it chylorrhoea gastrica.

Geromorphismus, recte gerontomorphia; Galen called it rhytidosis.

Haemophilia, recte philhaemorrhagia.

Hepatoptosis, recte hepatoptosia.

Hypoaemia; the better word is liphaemia.

Hypoglobulia is hybrid; the correct word is lipokytaemia or lipokythaemia.

Hypotrichosis, recte lipotrichia.

Hysterectomy, recte hysterotomy.

Hysteromyomectomy, recte hysteromyomotomy.

Ichnogram, recte ichnographema.

Idiotism, idiocy and idiotia are incorrectly interpreted in our onomatothesia. Idiotism refers only to pathologic disorders of language. Idiocy (*ἰδίωσις*) means peculiarity in general, and not necessarily pathologic, What is understood in our medical literature by idiotism, means in Greek *μωρία*; what we call an idiot means in Greek *μωρός*. Imbecility also means *ἠγιθιότης*, but this word is less usual in Greek medical onomatology.

Iridectomy, recte iridotomy.

Iridoptosis, recte iridoptosia.

Jejunitis belongs to the barbarisms of the appendicitis kind. Jejunum means *νῆστις, ιος* or *ιδος*.

Karyokinesis, properly translated means nut movement; what is meant is pyrenokinesia.

Laryngorrhoea—even the larynx does not run away.

Lupotom is hybrid, the correct word would be lykotom.

Mediastinitis, recte mesothorakitis.

Misoneismus, recte misokainia.

Mycoderma, recte myketoderma; mycologia, recte myketologia; mycosis, recte myketosis.

Myokymia, recte myokymatia.

Nekrodermitis, recte nekrodermatitis.

Nekrospermia, recte nekrospermatia.

Nephrectomy, recte nephrotomia. One of the most objectionable new formations for which the well-known kidney operator, Edebohls, is responsible, is—

Nephrokapsektomia; the renal capsule means epinephridion.

Oophorectomy, recte oothekotomy; oophorectomy, literally translated, means castration of an oviparous animal or all the oviparous animals. Oophoritis is oothekitis.

Orchidomeningitis, recte orcheomeningitis. There are *ὀρχις, εως* and *ὀρχίς, ίδος*: the former is testicle, the latter a plant.

Orchidopexia, recte orcheopexia.

Otomykosis, recte otomyketosis.

Otorrhoea—also the ear does not run away.

Ovarialgia, recte oothekalgia.

Pachyvaginitis, recte pachykolpitis.

Papillitis belongs to the barbarisms of the appendicitis kind. Papilla means *θηλή*.

Paraphrenitis is grammatically correct, but unscientific; what is meant is pardiaphragmatitis.

Peri-appendicitis. What is probably intended is paratyphlitis.

Peridectomy. It is impossible to say what this word is intended to convey.

Perivasculitis, recte periangionitis.

Pest means in Greek πανώλις, but that is not modern Greek, as our dictionaries assert; it occurs already in the ancient classical literature.

Phrenitis is not inflammation of the diaphragm, but a synonym of phrenopathy and phrenoblabia.

Psychosis means imparting a soul, life, animation, infatuation, but not as is stated in German, English and French literature, aberration of mind. I have repeatedly written on this error in detail.

Placentitis, recte plakountitis. The latter word has been erroneously called modern Greek.

Plicotomy is hybrid, recte ptychotomy.

Prostatorrhoea. Even the prostate cannot run away.

Pubeotomy, recte hebikotomy.

Pupillostatometer. Pupil means κόρη.

Radiography is correct, if it refers to radium, the metal; but wrong if it refers to aktinography. There is much confusion in consequence of the incorrect word-combinations with radium, so that it is sometimes impossible to know whether the subject deals with treatment by Roentgen rays or radium, if the term radiotherapy is employed.

Scarlatina means in Greek ὀστρακιά, and not as is asserted by German dictionaries σκαρλατίνα.

Stomatomykosis, recte stomatomyketosis.

Strumectomy, recte tongronotomy.

Strumitis, recte tongronitis.

Tenalgia, recte tenontalgia; tenorrhaphia, recte tenontorrhaphia; tenonsynovitis, recte tenontosynovitis; tenotomy, recte tenontotomy.

Terminology is hybrid. The Greek word is onomatology; to give a name is ὀνοματοθέτω, a nomenclator ὀνοματοθέτης, the giving of a name ὀνοματοθεσία and the naming ὀνομασία.

Tonsillitis, recte amygdalitis.

Tuberculosis is hybrid. The Greeks have the word φυματίωσις from φυμάτιον tubercle.

Urethrorrhoea is an impossibility.

Vaginism, recte kolpospasm.

Vulvitis, recte aidoiitis.

It has been objected that the medical onomatology should not be taken from modern Greek, but this objection falls to the ground, because our Greek brethren employ no modern Greek in their medical onomatology at all. Whatever "modern Greek" is in use in medicine, is made in Berlin (polypragmasia), or in New York (appendicitis), or in Naples (misoneismus).

In conclusion, I may be permitted to give it as my opinion that the works of the two Greek philologers, Hatzidakis and Papademetracopoulos, on the connection between the Greek of to-day and that of the classic period are of no less importance to science than the excavations of Schliemann and his successors.

[Written for the MEDICAL BRIEF.]

A Brief Resume of the Musculature and Fascia of the Pelvic Exit.

BY BYRON ROBINSON, B. S., M. D.,
Chicago, Ill.

(Continued from page 734.)

These ligaments are a part of the musculo-fascial support of the pelvic viscera. The vaginal tube supports the uterus by being well embraced by the levator ani fascia proximal and the levator ani muscle, and also by being well padded and surrounded by fascial planes of connective tissue fixed in its walls and adjacent structures. Fat pads and acts as a support by stiffening folds. The fact is the viscera are suspended by supports—ligaments, mesenteries—and supported by walls—muscle, fascia.

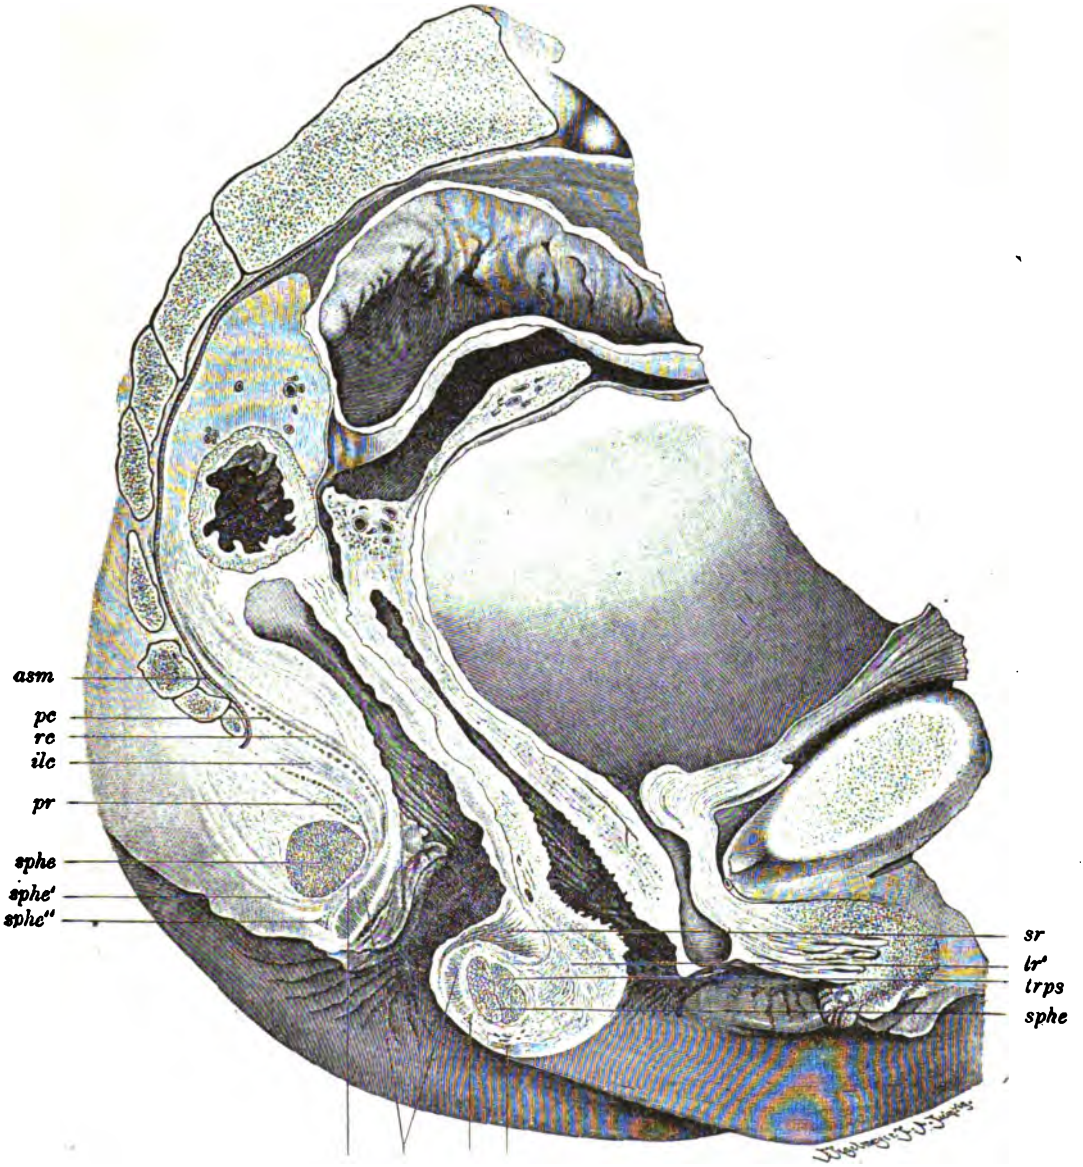
In colpoperineorrhaphy, it is well to remember that we have a fixed pelvic segment and a movable or displaceable segment. It will aid in repair. The movable pelvic segment comprises the urethra, bladder and vaginal walls. This segment is bound together by peritoneum on a very mobile base and by a considerable mass of loose connective tissue.

This segment becomes displaced by labor, distended bladder, vagina or rectum. If its fascial connections become torn, sacropubic hernia is inevitable. The fascial connections are considerable, proximalward to the pudendum, consisting of

the levator ani fasciæ proximal and distal and to some extent of the levator ani muscle. Sacropubic hernia, arising from lacerated fascia of the movable pelvic segment is recognized by the vagina and bladder bulging distalward at the pudendum and making the pudendum appear as a waist with the puckering string gone. The worst and most damaging cases of laceration are those which begin from proximalward and progress distalward, *i. e.*, the fascia begins to tear well proximalward in the rectovaginal septum on the sides of the bladder and vagina. These are the cases which present distressing symptoms; when standing are worse on account of disturbed circulation and are pronounced "prolapse" by the general physician. In such cases the ventral vaginal wall appears first at the pudendum then the cervix and finally the dorsal vaginal wall. The bladder gradually sags distalward and difficult urination is added to the already existing train of symptoms. In lacerations of the sacral segment of the pelvis the lesions are more visible. The perineal body suffers especially. It straightens, extends the fixed sacral segment and retroversion and inevitable subsequent sacropubic hernia results. The visible laceration of the perineal body was originally considered the chief requisite for repair and also the type of colpoperineorrhaphy. But the study of the pelvic fascia shows why the operation failed or succeeded. Frequently it may be observed that the perineal body is visibly torn, but no evil consequences follow, because the pelvic fascia remains intact. The rectum belongs to the fixed segment. It does not prolapse, but its wall stretches, elongates, expands, distends. As the advancing head forces ventralward and tears the levator ani fascia proximal and distal as well as the ischioperineal ligaments, the levator ani muscle also becomes deranged, but practically the restoration of the fascia restores the muscles. The muscular layers of the pelvic floor are two—superficial and deep connected—and blended at the perineal body both by the muscular and fascial relations. The deeper layer is the levator ani muscle which is directed distalward from the sides of the pelvis in the form of a boat or bowl to its attachments on the pelvic floor. The superficial layer consists of the transverse muscles of the perineum, which extend from the tuberosities to the center of the perineum and also the bulbocavernosus, which surrounds the vaginal outlet. All the muscles are related to fascia as the levator ani inclosed in double blades of fascia, *i. e.*, the levator ani fascia proximal and distal. The deep transverse muscles lie between the triangular ligament and Colles fascia. The bulbocavernosus and superficial transverse muscle lie between the two superficial perineal fasciæ. The ischioperineal fascia is but the thickening of the distal or dorsal border of the triangular ligament and Colles fascia. The significant importance of the fascia of the pelvis becomes at once apparent, not only in maintaining the integrity of the pelvic floor, but in all repair of the same. The pelvic fascia is the chief element in maintaining perineal muscular relations. The pelvic fascia may be divided into deep and superficial layers, according to the deep and superficial layers of muscles. The deep pelvic fascial layers are united to the more superficial pelvic fascial layers in the perineal raphe, maintaining the pelvic fascia as a unit. The superficial fascial layers of the pelvis are attached from the ischial tuberosities to the pubic rami and extend across the ventral pelvic outlet except at the pudendal orifice. Fascia may be lacerated without its associated muscle being lacerated. In perineal laceration the muscles lying between the fascial layers may become separated as to loops, bundles or as to the attachments of one or both ends. Also the fascia of the levator ani muscle may be lacerated in different localities and this allows incomplete repair.

When the muscular layer between the fascial layers separates, the muscular fibers retract irregularly toward the proximal or rather stronger end, leaving apertures which are difficult to effectually repair. The rupture and retraction of the levator ani with its fascia makes the deep sulcus found on each side of the projecting rectocele, because the fibers of the levator ani retract laterally toward the pelvic walls. It is evident there is a

deeper factor in perineal walls. It is evident there is a deeper factor in perineal lesions than visible lacerations. The deficiency in perineal lesions is not in proportion to the apparent extent of the injury. Every physician has noticed multipara with considerable external laceration of the perineum, with apparently lit-



A LATERAL VIEW OF A LONGITUDINAL (SAGITTAL MEDIAN) SECTION OF A WOMAN'S PELVIC MUSCLES.

FIG. 16. This drawing is made from a hardened female pelvis dorsal to rectum. The arteria sacralis media may be observed (asm), musculus recto-coccygeus (rc); (pc), musculus pubum coccygeus; (ilc), musculus ilio-coccygeus; (pr), musculus pubo-rectalis; (s), sphincter recti et vaginæ; (lr), fibro-elastic network arising from the elastic terminal tendons of the longitudinal rectal muscles and from the distal border of the muscles of the pelvic diaphragm which course to the skin surrounding the anus, partly toward the dorsal surface of the coccyx (sphe') as ligamentum ano-coccygeum; (sphi), musculus sphincter ani externus; (sphe), musculus sphincter externus profundis; (sphe'), musculus sphincter ani superficialis; (sphe''), musculus sphincter ani subcutaneous; (sr), musculus sustentator mucosæ—longitudinal bundle.—Ruedinger (after Holl).

tle discomfort, and with the pelvic organs but sightly disturbed, while in other cases with slight apparent lesions, complaints are serious, grave. I have seen extensive visible lacerations with almost no complaints and apparent health. Again, we may observe cases when the perineum does not appear lacerated, but the prolapsed vagina, the projecting rectocele and vesicocele appear at the pudendum in a remarkable degree. In fact, as Dr. Emmet remarks the pudendum looks like a bag which has lost its puckering string. There is a different explanation for each of the above classes. In one, the pelvic fascia has suffered in the lesion, and in the other, only a few muscle loops and possibly the perineal body. When the lesion involves the pelvic fascia its consequent result is that the circulation is deranged seriously because the vessels are held in definite relations by the fascial planes, hence the discomfort on standing and exercising is from congestion, deranged circulation and nerve laceration or trauma. Baker Brown simply united the torn tissue at the vaginal outlet. Seldom does this simple measure afford relief from perineal laceration, for subjects with such visible slight traces suffer but little. In general the operations for the relief of perineal laceration are a failure, if the rectovaginal septum (fascia and muscle) be not included within the grasp of the deep sutures success will not be obtained even though the pudendum be closed. The secret of Emmet's success lay in the denuding of the vaginal septum, *i. e.*, utilizing the tissue dorsal to the vaginal wall. In fact, if the levator ani fascia proximal and distal be not lacerated the subject suffers but little from the lesion, though the perineal body be torn completely to the rectum. The levator ani fascia proximal forming the gutter or sulcus on each side of the vagina is firmly blended with the vaginal canal as the same strong fascia in the male surrounds the prostate. In parturition, in perineal laceration we should not merely seek for lesions in the dorsal commissure of the pudendum, for that is due to the escaping head and shoulders and is visible, but we should search for concealed lesions of the strong fascia, the sulcus on each side of the vagina. The most serious lesion of parturition may occur without visible external injury. This lesion is in general a separation of the pelvic fascia from the vaginal wall. If the fascia be torn from this the dorsal vaginal wall will not be drawn against the ventral and the canal will be occupied by within; it will be like a collapsed bag. The fascia, together with the muscles, maintain the vaginal and rectal canals in the contracted closed condition, excluding air. The ballooning of the vagina with but little injury to the perineal body is indicative of fascial lesions, lacerations within the pelvic cavity along the vaginal canal. The vaginal rectocele is due to the lateral retraction of the levator ani fascia proximal and but little to the external laceration. The subvesical connective tissue is stretched, thinned, elongated and the vesical support has disappeared. The beginning of discomfort on assuming exercise is due to nerve laceration, nerve trauma, to deranged pelvic circulation, to dilatation and straightening, extending of veins to non-uniform support of the blood vessels and nerves by the proper connective tissue. The advancing head crowds the fascia ventralward and if the parturition be terminated without forceps the rents, lacerations, begin chiefly in the rectovaginal septum. It is well to decide what and where the laceration is so that tissues may not be either denuded or cleaved unnecessarily, for it is not infrequent to see tissues united which were never involved in the lesion. Perhaps sufficient has been demonstrated, anatomically and clinically, to show that the lesions of the perineum which disable and discomfort the patient are chiefly lacerations of the fascia and secondarily of the muscles. On this view we base our labors. If this be the case, we can easily see that Emmet secured success by denuding an elliptical area of the vaginal mucosa on each side in the vaginal sulci. The curve of the denuded area corresponds to the dorsal curve of the rectovaginal septum, and is situated within the introitus. Now, by introducing deep dorsoventral sutures, the levator ani fascia proximal and distal may be reunited, restoring the curve of the dorsal vaginal wall and the fascial layers at the pudendal exit. In reuniting the levator ani fascia proximal and distal

the levator ani muscle becomes also reunited, but in an imperfect degree. The levator ani is closely embraced by its proximal and distal fascial planes, as from its origin, insertion and relation it depends on its closely associated fascia. The restoration of the function of the levator ani muscle must be accomplished through restoration of its intimate associated planes of fascia. If success depended on the muscle chiefly it would be necessary in rectocele to reunite the separated levator ani loops ventral to the rectocle in the median line or raphe, so the symmetrical muscular action would be restored. It is true that to secure muscular action of the levator ani the loop must be so repaired that the vifers shall start to act approximately from the raphe on both sides, but this is accomplished by reuniting the levator ani fascia as near as possible in the median line, which brings the muscular loops with it. The levator ani fascia proximal and distal is really a sheath for the levator ani muscle to accomplish its functions. The sheath can not be torn without creating damage to the muscle. In rectocele, this fascia is so torn, extended and stretched that the ventral wall of the rectum loses its muscular support and projects ventralward. Whether the sutures be introduced ventral-dorsally or transversely, it matters but little, if they include within their grasp the levator ani fascia located in the lateral sulci of the vagina, and whatever is performed, to be successful, the rectovaginal septum composed chiefly of fascia, must be restored to reproduce the normal curve of the dorsal wall of the vagina. Mr. Lawson Tait's flap operation on the perineum accomplishes exactly what Emmet's operation in the lateral vaginal sulci does, with the exception of denudation. Both operations, when properly and successfully executed, result in the restoration of the continuity of the deep and superficial fascial layers of the pelvic floor, with the establishment of partial or complete muscular function. The deep sutures reunite the structures (fascia and muscles) at or near their normal points of attachment. Anatomically then, the objects to be obtained in an operation for colpoperineorrhaphy are (1) the restoration of the levator ani fascia, proximal and distal; (2) the reunion of the fibers of the levator ani muscle so that it will functionate—both fascia and muscle must have relations at the perineal attachment; (3) the restoration of the transverse perineal muscles which draw the vagina lateralward, causing it to remain patent; (4) the restoration of the ischioperineal ligaments in regard to the perineal body; (5) the dorsal curve of the vagina must be reproduced by restoring the rectovaginal septum; (6) a new perineal body, a "fixum puncture," should be restored so that the natural dorsalward curve of the rectum and ventralward curve of the vagina should persist, *i. e.*, normal relations should be established between the perineal center or body, on the one hand, and fascia and muscle on the other. The perineal body—"punctum fixum"—of pudendum surface relations should be restored.

The pelvic floor is composed of muscles, fascia, areolar and elastic tissue. These structures are interwoven into distinct, though complicated, relations and occupy the aperture of the pelvic exit. The pelvic floor is composed of two halves, the structure of which arise from the lateral walls and join in the median line. There are two muscles, two fasciæ and two ligaments of each kind, it is paired or bilateral. If one will carefully study in dissection the levator ani and the bulbocavernous muscle he will be impressed with their functional comparison. Both are sphincter muscles. Both have connection with skin as the majority of actual sphincter muscles possess. The three points of insertion of the bulbocavernous may be considered as one muscle. They contract together and have a similar function. The common feature of the two muscles is their attachment to the terminal fibers of the rectum and vagina. The sphincter ani is closely united to the muscles of the pelvic floor by tendons and fascial attachments. The object of the muscles of the pelvic floor is to control the distal ends of the vagina and rectum, and to accommodate urination, defecation and parturition. Fascial structures are common to muscles which afford sustaining and controlling power, as those of the abdomen, dorsum and thigh.

Some Neglected Features in Primary Nephritis.

BY J. W. CRISMOND, M. D.,
Anderson, Ind.

The first article that caught my eye and fancy, in opening THE MEDICAL BRIEF of July, was the significant editorial entitled, "Are You Mentally Free?" The inspiration gathered from reading the said editorial is responsible for this effusion in reference to nephritis.

It certainly means much to be mentally free, and it frequently requires heroism of the highest order to be brave enough to break away from preconceived opinions that have nothing to plead for their existence save reverence that is instinctively paid to hoary age.

Theories are, at the best, but brittle productions, and in the face of demonstrated facts fall to pieces for the want of cohesive verity.

The only tribunal in true science is the tribunal of facts, carefully arranged and sifted.

To treat a disease intelligently and satisfactorily implies a knowledge of the cause that underlies its existence. This is an apothegm that can not be successfully challenged, and should be rigidly adhered to. He who would prove himself master in the arena of renal diseases, should not only master its anatomy and physiology, but he must be learned in its clinology, and especially skilled in urology.

The fundamental cause for nephritis has not been determined, but that is no reason why nephritis, in its incipiency, should not be detected and treatment instituted, to arrest its progress, before it reaches the lesional stage—irreparable.

In its incipiency nephritis is as curable as any malady the system is heir to.

In its secondary stage we possess no specific for its ravages, hence the treatment must necessarily be symptomatic.

Pardon my tautology, and what seems to be digression, but I wish to impress this idea upon the mind, to obtain the best result from antitoxin in diphtheria it should be administered in the *earliest stage* of the disease, and not wait until the whole system is profoundly saturated with toxine.

Your attention is called to this point for the purpose of emphasizing the importance of an early diagnosis, in order to treat and conquer the disease in its incipiency, while it is curable.

We will endeavor to point out briefly some of the neglected features which are very essential to perfect our diagnosis in early nephritis. Prior to the nineteenth century nephritis was known as dropsy and treated as such; thus mistaking one of the late symptoms for renal disease.

In the early part of the nineteenth century Richard Bright, an English physician, discovered that dropsy was only a symptom of what was regarded as a pathological entity.

Nearly a century has passed into oblivion, and we are no nearer the solution of the etiological problem than in the time of Richard Bright.

This being true does not render us blameless for our mistakes and failures, should we neglect to apply the most approved methods and technique to discover the disease in its incipiency.

Roger declares that "Examination of the urine should be made in *all* cases and in *all* patients."

This may appeal to some persons as being irksome, superfluous and an unnecessary routine.

But when the importance of this procedure is better understood the inestimable value of this seeming irksome task will be more fully appreciated.

This allusion to a duty, generally neglected, is not a commonplace or trite bit of persiflage; for it should be remembered that in science, and especially in medicine, the contemned and despised theory of one generation is frequently the gospel of the next.

The declaration of Roger is not of a visionary, the conclusions of an overwrought enthusiast.

But, rather, it is the product of an eminently safe and sane teacher; one who fully recognizes the fact that nephritis develops so unconsciously, and so insidiously does its destructive metamorphosis progress, ere the patient or the physician is aware of its presence, that the disease, as a rule, is far advanced

before it is discovered and treatment instituted.

This fact accounts for the failure to cure in nine-tenths of the cases treated.

Experience has taught me the value of urinalysis (not test-tube methods) in determining the condition of the kidneys, and in detecting nephritic indications in its earliest stage.

Our knowledge of the science of medicine is poor capital, indeed, if it is not used to detect and arrest disease in its remedial stage, whereby we will be the better able to render assistance and restore the sick to health.

What the sick demands at the hand of the physician is help. The sick person cares but little for the profundity of the physician's erudition if it can not be utilized in restoring him to health in time of need.

"We are living in an age when it is proper to live and when *all* are interested in medical matters.

"It is not that medicine has in any sense of the word revived, but that she has simply changed her attitude of observation.

"What is characteristic of these modern days, so far as medicine is concerned, is the high place we assign to the study of the origin of disease."—Bouchard.

"The study of the urine in reality should never be passed over; it affords the physician indications of the highest importance."—Roger.

"A sufficient and exhaustive knowledge of the characters of the urine is a point of the utmost consequence to the physician, since the changes which it undergoes are the expression of numerous morbid processes and their intelligent interpretation affords the surest aid to diagnosis."—Von Jaksch.

Mark his language! Von Jaksch does not say a word about test-tube examination of the urine. He says a "Sufficient and exhaustive knowledge of the characters of the urine." To expect to gain this knowledge from a test-tube examination (?) would be absolutely absurd—nonsense gone to seed.

To declare that nephritis existed simply because of the presence or the absence of albumen, per test-tube *data*, is not only unreliable but often a grave error.

Remember this very important truth, namely, many cases of interstitial nephritis run their entire course without a trace of albumen in the urine, and, again, there may be albumen in the urine and no renal lesion present.

So many problems present themselves for solution in renal troubles that require keen discriminating power to solve, it behooves the conscientious clinician to familiarize himself with the pathology of the secretion and excretion of the urine, and also the normal composition of the latter, together with those fluctuations which are included within the range of health.

In view of the great variety of indications and symptoms of nephritis, any one of which taken singly might easily mislead the diagnostician, one can not be too cautious in weighing all the conditions before reaching final conclusions.

By disregarding the injunction to "weigh all the conditions before reaching final conclusion" is where the danger line lies, and at this point we are apt to come in contact with the reefs and shoals in making our diagnosis.

In the following analysis of cases I do not wish to be understood to imply that the symptoms here enumerated are only common to nephritis, by no means; but I do affirm that all nephritics present one or more of these neglected features or symptoms in incipient nephritis.

A patient comes to us complaining of some gastric ailment. We conclude, *a priori*, that it is an idiopathic gastric malady, without taking the pains to ascertain whether or not it is simply a sympathetic condition, the result of renal disease. We treat the case for dyspepsia. We have allowed the patient to make the diagnosis for us. The renal lesion progresses while the physician blunderingly, ignorantly and lazily fritters away valuable time trying to subdue an effect while the cause is left undisturbed.

Another complains of a pretty constant occipital neuralgia; it is an old complaint; has tried various remedies and different physicians, and has received only temporary relief. The kidney in disease has never been considered in rela-

tion to constant occipital neuralgia. It is so much easier done to give an anodyne; and again, it smacks of such wonderful intuitive wisdom.

Here is a victim of persistent vertigo appealing for relief from a condition that is not only a physical detriment to his well-being, but is also mortifying to his moral sense.

We can think of but one culprit who is responsible for this disturbance, and his name is gastric neurosis, accompanied by his reflexes, *etsequentia, etcetera.*

The physician is not infrequently called on to cure epistaxis, with the volunteered information that the affliction has been in existence for a certain number of days, weeks, or may be months.

That it makes its appearance without any apparent cause; upon assuming certain bodily attitude, or under the enervating influence of excessive heat, or it may be brought on by the frigid effects of very low temperature, etc. To clarify the situation we will assign the applicant for relief to the masculine gender; and that he is free of all clinical evidence of pulmonary tuberculosis. We treat the symptoms of this case, but neglect to seek the cause.

But of all ailments, of what is considered by many as only of minor importance, for which help is sought, heart troubles leads the clinical van of all other afflictions.

The cardiopaths, representing one of the primary symptoms of nephritic disease, are numerous. But so far as receiving proper clinical recognition that their condition demands at the hand of the conscientious clinician they are, in too many instances, put on a simple cardiac sedative, tonic, or stimulant, as the case may indicate.

It is so much easier to look wise and assume the air of transcendant importance than to investigate the urine for renal morbidity in order to locate the cause of the cardiac disturbance.

Thus we might continue to enumerate important primal clinical symptoms, which are ever present, but whose renal value are overlooked, or ignored because of criminal indifference.

I have been betrayed, unconsciously, into a longer disquisition than I had intended on the several features of this paper, hence I must abbreviate my further remarks and leave much unsaid that is really of value and interest along this line of thought.

Now then, with emphasis, if you please, I will say, albuminuria is only a symptom of doubtful clinical significance, and of itself is no evidence of renal lesion. The only trustworthy *data* is to be found in the physical, clinical and microscopical examination of the urine.

This will afford information of the utmost consequence, the evidence of which can not be impeached.

To review the several forms of renal lesion is beyond the scope of this paper. Permit me in closing to repeat that nothing short of complete quantitative, chemical, miscroscopical urinalysis, is sufficiently accurate to determine the *renal status.*

The present age demands facts and figures, grounded upon the correct interpretation of symptoms, which will lead to the primal cause of the disease, and not fads and fancies, that will-o'-the-wisp which misleads the careless, lazy dilettante into the error of regarding the consequences as the real pathological entity.

Right Living.

BY JAMES BURKE, M. D.,
Manitowoc, Wis.

Man is governed by his habits. His physical and spiritual well-being depends on their despotic sway. Unphysiologic living creates an artificial grade of cellular function, and, if long continued, creates a changed cellular construction. Right living presupposes harmony of action, physical, mental and moral. Such symmetrical development achieves the best there is in a man; an impediment to the free action of the developed man, in any of these essential attributes, hampers the usefulness of the individual to his fellow-man; the measure of worth of a person consists of his services rendered in uplifting his fellow-man. Singleness in the pursuit of material wealth is the bane of civilization. The educated and favored

few owe all they possess to the mass of their fellow-beings. Happiness itself is fundamentally dependent on our services toward promoting the greatest good to the largest number. To bring the matter home to our own profession, we are dutifully bound to give a full measure of our scientific knowledge to setting the people right on the liquor question, the economy of their utilizing the abundant medical services always near at hand in perpetuating the good health of the various communities, with its consequent monetary advantage; the venereal subject is a paramount issue with the great minds of the medical profession, and bids fair to bring forth ripe, rich fruits.

The correction of popular errors regarding the use of alcoholics for beverages and medicine is urgent. Alcohol in medicine is a fallacy; its physical composition precludes its use to build up normal tissue; it is a protoplasmic poison; its avidity for water radically changes the quality and quantity of the digestive ferments. This inherent property of alcohol upsets the delicate combination of nitrogen, phosphorus, and glycerine, in the construction of the brain, and constitutes the drunken state. Its destruction of the digestive ferments of the stomach, from its being retained there until its final absorption into the general circulation, is well known. The liver suffers severely from the extra load of abnormal protein thrown upon it for vicarious action, in the effort to convert the heterologous protein into pabulum homologous with the tissues of the host; this vicarious action, though failing for the greater part, serves to derange the liver, first in its proper nervous supply, with consequent physical changes in its cellular function and ferments, and, finally, establishing hypertrophic changes of its connective tissue framework.

If the life of the tippler is prolonged a contraction of the capsule sets in, and squeezes the life out of the abnormally secreting cells of the liver.

Other tissues also suffer deterioration from the absorption of hybrid and heterologous protein from the walls of the intestines into the general circulation, where the blood and other tissues are burdened with the presence of foreign protein, which they stow away in the tissues until some physical or medical force resolves them back into the blood and fluids, where, if they meet a cognate proteid entity, an ultimate primary unit of which unites with it to form a complete chemical entity, a harmless excretory product is formed; but if a temporary chemical union is formed with a pseudo or other incomplete affinity, a leucomain is formed, the toxicity of which depends on environmental conditions. The leucomains and vegetable alkaloids, and some other active principles are allied, the ultimate component units of which are chemicobiologically interchangeable, in forming new compounds, and in rounding out incomplete entities for excretion. The neutralization of the leucomains in the walls of the intestines should precede that of the systemic leucomains, by the indicated use of emetine, sanguinarine, podophyllin, chionanthin, juglandin, or hydrastin.

Intestinal asepsis should be practiced to prevent further fermentation of the bowel contents, thus limiting gaseous distention, and allow the bowels to assume their normal caliber, assuring a better circulation in the secreting glands of the intestines, thereby furnishing a better quality and quantity of digestive ferments.

[Written for the MEDICAL BRIEF.]

The Most Reasonable Faith.

BY R. C. CAVE,
St. Louis, Mo.

As stated in a previous article, faith in the doctrine of divine immanence seems to me far more helpful than the faith of either materialism or orthodox theology. It also seems more reasonable. It conceives of God, not as an all-powerful being throned above the world, and shaping events by pressure from without, as a potter shapes clay; but as a wise and loving spirit resident in nature, always expressing himself through natural forces, and unfailingly making for good. It views the life of the world as a gradual evolution of this divine spirit—a gradual progress toward the perfect. It

is true that this faith seems to be opposed by some facts of existence, but that is also true of every other theory of things taught by men.

The doctrine of materialism seems altogether incompatible with the facts of mental experience. The materialist may tell us that what we call soul is merely "the series of mental phenomena which make up an individual mind;" but the fact remains that there is something which takes cognizance of this "series of mental phenomena," and must, therefore, be different from the "series" itself. This something is conscious of perceiving, remembering, observing, comparing, feeling, desiring, willing, etc., and it is conscious of these acts as different from, performed by, and belonging to itself. The existence of this something—this Ego—which possesses organs and thoughts, but is distinct from both organs and thoughts, is so inseparable from the facts of mental experience, that even the materialist is compelled to recognize it, indirectly, when he attempts to explain the operations of the mind. It has been truthfully said, that "however much assailed or disowned, the conception of a mind or conscious subject is to be found, implicitly or explicitly, in all psychological writers whatever—not more in Berkeley, who accepts it as a fact, than in Hume, who accepts it as a fiction."

No less true is it that many facts of existence seem to be incompatible with the faith of the orthodox theology, which is based on belief in the existence of a personal God, who is omnipotent and benevolent, and who created and governs all things "according to his sovereign will and pleasure." Is it possible to reconcile the terrible facts of sin and suffering with the existence of such a God? Would an omnipotent and infinitely loving Creator have permitted sin to enter the perfect world he had made, and entail misery and woe on all the generations of mankind? As well ask if a loving father, having the power to prevent it, would permit his children to fall into wrong and pain and wretchedness. Theologians tell us that God "was pleased, according to his wise and holy counsel, to permit" sin, "having purposed to order it to his own glory;" but, surely, it was not very benevolent to permit his creatures to go wrong and bring suffering upon themselves in order to add to his own glory. We are told, also, that God permits suffering because he purposes thereby to perfect and save men; but a truly benevolent being would not save men through suffering, if, clothed with omnipotence, he could save them just as well, or better, without the suffering. Look at the matter as we may, the facts of sin and suffering seem to be incompatible with faith in a Creator and Supreme Ruler, who is both omnipotent and benevolent.

It must be admitted that the facts of sin and suffering seem to lie against the doctrine of divine immanence also, but they do not lie against it with the same force. The doctrine of a divine spirit resident in nature, and unfailingly making for good, involves no such glaring inconsistency as we find, for instance, in the belief that a loving father permitted his son to be crucified to save those who would believe on him, when, being omnipotent, he had the power to save the whole human race without that crucifixion; for the spirit in nature is not omnipotent, in the orthodox sense. This spirit can not bring worlds into being by "the breath of his mouth," and accomplish any desired good by merely commanding it, but must work out the good along natural lines, and through natural forces. There are cases, it is true, which, considered separately, seem to show a failure of this spirit to work out good at all; but, when we consider these cases as links in the chain of evolution, we find that even they are agents for good, impelling forces in the world's onward march, making for the steady gain of man. Sin and suffering are among the means which the divine spirit uses, and without which the world could not be brought to higher and better things. It is in the hard school of experience, through mistakes and sins and sufferings, that mankind has learned wisdom, and been led slowly forward in the march of progress.

Some Observations Upon the Relation of Sugar to the Genesis of Cancer.

BY T. H. EVANS, M. D.,
Philadelphia, Pa.

Some merriment greeted the announcement by an English physician, recently, quoted as saying that a diet of too much carbohydrate value might predispose to tuberculosis.

After the merriment subsided, students of medicine continued to inquire into the possibilities.

The studies of Solis-Cohen, of Philadelphia, had for years suggested the relation of tuberculosis and carcinoma, and now some developments point to the two and a third disease, namely, diabetes, as forming a group in etiology, and that one due to the faulty reception of sugars in the system.

The studies of men under the Collis P. Huntingdon foundation in New York have shown that some of the products of sugar are found, and in more or less relative proportion, in and around the degenerated tissue of cancerous nodes. This is not a chance relation, in all probability. Some slight clinical investigation has indicated to me the very important effect upon cancer of the liver that a reduction of sugar in the diet may have, and in connection with the employment of the Beard treatment, that by hypodermic administration of the pancreatic ferments, trypsin and amylopsin.

Of this latter I would like to speak, if briefly.

Before making a clinical observation have the urine examined for albumen and for sugar. Diabetic symptoms occur in late cancer, and at times early.

There is usually some icterus, and many of the symptoms found and the physical signs are similar to those of indigestion, as in children who have indulged in sweets to excess.

There is much gastric insufficiency, and this symptom, as well as the signs of hepatic insufficiency, are favorably affected by the employment of the absolute diabetic diet.

The eye clears and the tongue improves. There is less melancholy and more appetite.

Even so much as this would justify some such regime. But another result seems probable. (Judging by my limited experience.)

Doses of the pancreatic ferments, which ordinarily must be given with caution, are less violent in reaction under the diabetic diet, and I have found in check experiments that very large amounts of the ferments so administered afford little disturbing symptoms, such as have been reported by observers, both in America and abroad.

The purpose of this paper is largely empiric, if I may so term the request for greater clinical tests of these observations. I have found that the toleration of hypodermic doses of trypsin and amylopsin is marked. I ask any who employ these therapeutic agents to try the effect under the absolute diabetic diet.

As a caution, it may be added that this diet may have to be broken. The appearance of diacetic acid or oxybutyric acid in the urine is taken for a signal of entrenchment upon the reserves of the general nutrition, and that the fats are being broken into with some probability of disaster to the body's economy.

Why the liver is the site of so many cases of secondary and, frequently, of primary cancer, is very likely to be understood in the light of the function of the liver.

In many cases of anemia in the hepatic tissue there are observable rings of hemic pigment, and that this iron of the blood is thrown down so conspicuously in the liver substance may be taken to show that there is some obstacle to the red cells of the blood, and that they are either dissolved or impeded in function. But with the oligocythemia present, it may be suggested that the red cells are destroyed, and, possibly, as by fire. The use of carbon in the physical being is chiefly for conflagration. The muscles employ the sugar and the ferment in the blood-lymph stream (derived from the pancreas) to furnish heat and motion.

The liver is the great glycogenic center.

These points are evident, and plainly direct our eyes to the carbohydrate metabolism.

It is with a feeling of blindness that is very annoying, that we look and fail to see further.

The spleen may be removed without danger to life, in most instances. But the heart and the liver seem to center great primary functions. There are few other organs which are so vital to us. In time we shall come to understand the particular place in the chain which they strengthen or, indeed, compose. It is to the physiologist that we look, and with eager eyes.

2359 North Front Street.

[Written for the MEDICAL BRIEF.]

A Disease Without a Name.

BY J. WATERLOO DINSDALE, M. D.,
Prescott, Ariz.

The regret often comes to one who is aged that they can not live over again, and have the same knowledge to start with that they have accumulated on the voyage of life. It must be a bitter regret. The only advantage to be derived in living over again, in our estimation, is to go over the ground and do more good than we did on the first journey. The following attempt at doing good while we are still in the flesh:

There are thousands of men in the world, especially the United States and Canada, who are not sick, but they are not well. They are listless. They are weak. They do not have kidney disease, but the back is weak. They may have some local trouble with the lungs, liver, kidneys, or the digestive apparatus, but they doctor their local trouble and it appears better, and they are still weak. Their minds are not sharp. They miss bargains. They are irritable. They can not see correctly into their circumstances. They exaggerate trifles and diminish the mountains. They are stubborn in mind, but yet are easily persuaded into or tempted into excess. They are unfit judges of their own standing, and the worldly verdict is that they are "off their base."

There are women who are in the same category. They dress well and are fairly well behaved. They are not ailing, especially, but they are invalids.

They patronize a physician, and yet they hesitate to take medicine. They know medicine does not permanently help them. They go to different doctors' offices and hear a different story at each office.

One physician assures them that "womb disease" is killing them. Another points to the liver and says, oracularly, "It's out of order." Another specialist declares that rectal medication is needed, and if piles, pockets, papillæ and what not, were out of the rectum, all would run serene in the bodily economy.

But all are only stepping stones or mile posts on the march to decay.

If in moderate circumstances, the patient lingers along a few years and drops into the grave. If wealthy, specialists are consulted, and the end is hastened by a recourse to those commonly prescribed "nerve stimulants" (but which are nerve destroyers), strychnia, bromide of potash, belladonna, opium. We say the end is hastened, because in the disease without a name the more drugs the quicker comes destruction.

We have known an entire family swept into the grave from this disease, while doctors declared and certified that the dead were victims of consumption.

So, too, in the case of the woman. She is physically and mentally depressed. She has no special organic disease as, for instance, cancer, but while cancer has, at the present, ceased to inspire the horror it formerly did, all women who have the disease without a name readily succumb to any intercurrent disease.

We attended, some years ago, a lady dying from this disease, and the husband rallied after the death of the wife, and in a year married again.

Both himself and second wife are now suffering from this malady.

We know of a clergyman satisfactorily settled, with a good living. He had the disease. He changed climates, grew worse, changed again and died. The wife is partially recovered.

Can these people so diseased be distingished? We think they can. Sadness or mild sorrow is a distinguishing symptom.

Of the one hundred thousand doctors in the United States fully two-thirds attempt to combat this "disease without a name" by drugs, chemicals or nostrums

of no earthly value. It is not too much to say that fully one-half of all named diseases are caused by this disease without a name.

We do not believe there is a hamlet inside the boundaries of the nation where there is not a victim to this disease without a name.

What causes this disease?

To this question we reply that there is only one cause. Unlike fevers, which may come upon a person from a multiplicity of causes. (At this point we desire the reader to understand that we do not class fevers of any kind as diseases by themselves; a fever is a symptom of a disease, but the fever itself is not a disease. And mark this, the time is coming when this doctrine will be taught in the fashionable schools of medicine.) This disease has only one cause, and this cause is perversion of the sexual functions.

We do not now allude to this sin and folly of youth, masturbation or self-abuse, a practice which is left in the dark to the unfortunate youth, and is only too frequently learned of from the outside world to one's detriment, instead of from the mother or father, as it should be, and learned of to be shunned.

We assert that this disease without a name is a perversion. Let us clear it up a little.

When it comes to pass that a man is married to a woman, and the sexual passions are gratified, while the man refuses to become a father, or the woman refuses to bear children, they resort to a number of devices to prevent conception—to prevent the egg of the woman from becoming fertilized by the seed of the man.

The most common of these preventions is a perversion. Before the marital act is completed they separate. It is a crime for committing which God slew Onan. This secret, unspoken-of crime, this loss of seed in the male and the corresponding loss of force in the woman is the cause of this common disease without a name.

In the male this disease is the more formidable, because it is a tabooed subject by the doctor and patient. The ordinary physician can not probe the acts of the home life. He says—and says truly—"If I mention those subjects, no matter how much they may now respect me, they would soon join in hating me for my meddlesome interference." So the doctor is ordinarily powerless for good, and his silence, under the circumstance, is a necessity. The crime goes on unrebuked, and in too many instances the victims are ignorant of the results that follow. Sexual gratification takes place, but the "seed is spilled." But not all spilled. A part of this seminal fluid can not be ejaculated or voided, and this suddenly chilled, inert, dead and retained semen (for it can not all get out through the ejaculatory ducts, and the seminal vessels are not fully emptied) decays and is reabsorbed into the system. It destroys the spinal cord. It softens the brain. It changes the countenance from a clear, arterial red, to a putty color. It stoops the shoulder. It dazes the intellect. From a healthy product it becomes a virulent poison. The man is no longer an individuality. He is a walking death. A bunch of festering corruption, which is hastening to the graveyard. This is a cause of enlarged prostate glands. A cause of paralysis. A cause of palsy. But, above all this, perversion of the sexual instinct is a cause, and the sole cause, of the disease without a name.

But the woman does not escape. If one thinks the unfortunate woman ever escapes from any punishment, read history. The woman never escapes. Her punishment meets her on the way.

In the case before us, the woman, having become passionate, is suddenly shocked by an abrupt ending. The uterus, especially its mouth and neck, lacking the necessary and needed natural moisture that is provided for it in the semen of the man, is heated and congested. Here commences those dreadful troubles of the uterus which so often assumes the cancerous form. She suffers as long as possible in silence. Under the doctor's hands she is cauterized. Fatal mistake—she is tamponed, flexed, straightened, glycerined, pessaried, supported, treated, excised, and, finally, the uterus is extirpated or taken out. She lingers a year or two, and is placed in the grave.

Wretched, wretched humanity!

Where do these evil teachings and practices commence? In many ways.

Oftentimes the mother advises the married daughter to not bear children.

We believe they are good Christians, but in the case before us we should rather take our chances with the Atheists for future and present rewards than to believe and act as this couple have acted. It was Lord Bacon who said:

"Atheism leaves to man reason, philosophy, natural piety, laws, reputation, and everything that can serve to conduct him to virtue. But superstition destroys all these and erects itself into a tyranny over the understandings and consciences of men."

This habit of sexual perversion is worse, even, than superstition, since it directly destroys body and brain.

What can be done in this disease without a name? Stop the producing cause.

If the woman and man have resolved not to have children—*keep apart.*

For the man who has a wife that refuses to bear children is, to all intents, divorced. The farther he can keep from such a woman the better for his body, and the safer for his soul. No man whose seed is part spilled and part retained, can long retain his intellectual faculties.

To the woman we would say, if your husband does not care or desire to father your child, in the name of God leave him. Do not let him destroy you, as he certainly will if you permit his half embraces. To botn we would say, if you can not complete the act with the utmost freedom and love, and if there is any hindrance, obstruction, repugnance, or, in short, if there is anything except the warmest trust, love and affection—*separate.*

Go out upon the street and look at the passers-by. Look at the white faces, hollow cheeks, void expressions, and gnawing, undefined care that is sapping the life from the body. Listen to your preachers, and hear their flimsy platitudes, and their trashy oratory, and ask yourself how many are continent? How many are pure? Call up the faces of your dead friends, and see how many were victims to a disease without a name. Ask yourself how you stand before your own conscience and before God.

Do not stop with examination. Resolve to do right.

[Written for the MEDICAL BRIEF.]

The Moral Survival-Value of Oscar Wilde.

BY AXEL EMIL GIBSON, M. D.,
Los Angeles, Cal.

The present revival of the letters and philosophy of Oscar Wilde has its significance rather as an indication of the present state of public morals than in any intrinsic value of his writings. The storm of emotions raging both for and against "Salome," shows by its very intensity, and by the subsequent *editions de Luxe* of his books flooding the book market, that the author has found at least a passing response in the public mind for his principles of art and morals.

This response has its strongest support in what might be called the posthumous "confessions" of Oscar Wilde contained in his famous book *De Profundis*—as in it is found the supreme effort of his life to vindicate the principles and modes of conduct which gradually effected his moral and social breakdown.

Without doubt *De Profundis* stands for the best and strongest ever expressed by its author. Written between prison walls, where the conjoined influence of isolation and social condemnation stirred into life and conscience whatever feelings of sincerity and faith of which his nature was capable—the document stands as a final and consummate personal appeal to human sympathy. It brings out the focalized aspirations and hopes of a mind agonized by the ambition to remove the stain of civic dishonor fastened on his life by his social judges.

Yet, with all its pathos of sentiment, the book fails to impart any real moral lesson to its reader. It lacks sincerity and moral force. The author gives the impression of aiming at a restoration of reputation rather than of character; with the forgiveness of man as by far the stronger motive than the forgiveness of God. All throughout the entire cycle of his "confessions" one feels the presence of half-veiled or half-felt motives; the desire to be cleared, not so much from the accusations of a morally outraged conscience as from the official stigma thrown upon his life by the misfortune of being

convicted of what his public accusers chose to call criminal conduct.

What gives to Oscar Wilde his main interest, however, is not his more or less successful pleadings for public sympathy, but the symbolic relation in which he finds himself to the art and general culture of our age. His position in modern life is by no means unique or exotic; it is the mere striking projection of a general tendency of the time to substitute life with the science of life, ideal with artifice, morality with intellectuality—a tendency which sets its stamp of egotism and personal advantage on so many of our private and public undertakings.

And while the degenerate life of types like Oscar Wilde add force and momentum to the intellectual-ward and sensual-ward tendency of modern culture, it is, on the other hand, the very acceptation and application of these principles that makes degeneracy like Oscar Wilde's possible. The individual with his vices and virtues stands in the same relation to the commonwealth as a physiological function stands to the bodily organism; the specific expression of a constitutional state. A perfect organism can show no diseased features.

It is in the isolated ascendancy of the intellect, however, that the life of the public morals are threatened. For intellectualism, if not softened and qualified by affections and feelings, tends towards mental overgrowth, self-sufficiency, egotism and indifference to the conditions, the aims, needs and failures of our fellow men. Most of the motives actuating the purely intellectual life, even if promoting social benefits, spring from a desire to obtain public recognition and rewards, rather than from motives contained in the act itself.

And even where deeper minds are engaged in wrestling with the world-problem, and the small motives of personal vanity are merged in the larger interests of scientific seriousness, if intellect alone leads, the driving impulse is more often found in a feelingless curiosity for the mere incidents of research, than in a warm, living sympathy for the increase of human welfare that may accrue from the researches. And it is, furthermore, in this lack of humanizing motives, with the accompanying failure to feel the heart-throb of the larger, fuller, deeper life, that induces the scientist to concentrate his mind on the appearance, rather than on the soul of things; in the rigid analysis of symbols, rather than the synthetic adjustment of principles. We trust in our heads more than in our hearts, in our touch more than in our feelings, in our reason more than in our intuitions. Hence, the so frequent occurrence, that in the life and labor of a man we pay less attention to the purity of his feelings than to the incisive force of his intellect. And yet without the leadership of purified feeling the intellect, however sagacious, must ever fail to rise above the vicious circle of mere scientific guesswork with its theorizing and copying. In the pure feeling we have the sesame that opens the sanctuary, both to art and to nature, enabling the thoughtful and intuitive to decipher the signatures and count the heart-beats of the noumenal, ideal world-life expressed in terms of concrete organized existence.

* * * * * * *

In Oscar Wilde we find a type of this intellect-governed mind. Responsive to the analytic and isolating tendency of the age, he loses sight of the larger, unifying, synthetic view of life, and sketches his world-picture through the refractory, foreshadowing medium of a sense-fed and sense-limited intellect, demanding the subordinacy of feeling to intellect, of moral to form, of the ideal to the sensational, the unity of principle to the diversity of symbol.

Perhaps, in "Dorian Gray" the author has preached this gospel of sense, with its triumph of mind over morals, with more audacious frivolity than in any other of his writings. Without hesitancy he announces "that the value of an idea has nothing to do with the sincerity of the man who expresses it," and that "the moral consciousness of an individual has its genesis in the liberation of the associated sense-impulse." Yet, notwithstanding the soul-dissolving maxims of "Dorian Gray" as an expression of character and individuality, this book has more literary value than "*De Profundis.*" For even if in "Dorian Gray" we find the moral life at its lowest ebb, the presence

of sincerity sets free a redeeming quality in its degenerate form. Thus, while in "Dorian Gray," with all its degenerate philosophy, the author has the moral courage to appear without mask or pretense, in "*De Profundis*" he is lost in a chaos of conflicting emotions, untrue feelings and melodramatic pathos. And though his appeals to the sympathy of the world are delivered with classic eloquence, artistic form, poetic diction and intensity of self-interest, they lack convincing force through the absence of sincerity of feeling. An emotion, to take effect in the heart, must have its genesis in the heart.

Without sincerity there can be no real remorse or repentance. "*De Profundis*" exhibits a sense of violated rights rather than a confession of sin. "Terrible as was what the world did to me, what I did to myself was far more terrible still." For from his point of view, his moral responsibility involves but himself and his own personal welfare. The scores of moral wrecks in man and womanhood, due to the soul-poisoning influence of his life and writings, seem to be of no significance to him. His mind is absorbed to its last power with the injury the world inflicted on him, but oblivious to the terrible things he inflicted on the world. He is a victim of merciless circumstances—the martyr who is not even permitted the redeeming triumph of wearing the crown of martyrdom.

In going over this strange commingling of pathos and cynicism, of high-soaring emotions and groveling platitudes, insane self-idolatry and morbid humility which forms the substance of the "*De Profundis*," one feels inclined to doubt whether his suffering has fundamentally and intrinsically advanced him a single step on the path of life's true philosophy. "Morality does not help me," he exclaims. "I am a born antinomian. I am one of those who are made for exceptions, not for laws. But while I see there is nothing wrong in what one does, I see there is something wrong in what one becomes." In statements of this nature Oscar Wilde, with cynic plainness, lays bare the elements and forces at work in his moral construction. A philosophy of life which ignores the very instrumentalities and possibilities of life, lulling its devotee into the forlorn hope that futurity stands for self-generated energies, disconnected and independent in their relation to present efforts; that *becoming* is possible along any other line than that of *being;* or, in other words, that a fruit can exhibit characteristics and qualities different from the tree on which it is grown, and attaining its perfect state of maturity without passing through the evolutionary stages of bud and blossom, furnishes a very hazardous principle when applied to moral conduct. An individual who regards himself as an existence made up by disconnected, independent stages of growth, naturally will succumb to a sense of irresponsibility as to the condition and attitude of his present phase of evolution. On the other hand, to the morally self-conscious and sane individual every moral or mental attitude must go to form an element or energy—imperishable and inescapable—by and through which the rise or fall of a character has its only logical course and basis.

It is in his thirst for exalted personal uniqueness and moral irresponsibility that Oscar Wilde encounters the most serious obstructions for his moral development. Finding his genius too complex and too highly specialized for the action of ordinary moral nature, he considers himself justified in dispensing on a similar basis with the services of religion. "Religion does not help me. The faith that others give to what is unseen I give to what one can touch and look at. My gods dwell in temples made by hands." * * * "When I think about religion at all, I feel as if I would like to found an order for those who can not believe; the confraternity of the faithless, one might call it, where, on an altar on which no taper burned, a priest, in whose heart peace had no dwelling, might celebrate with unblessed bread and a chalice empty of wine."

It is difficult to know whether the author is to be taken seriously or not in these challenges, as to the value of moral and religious principles. There is one stable feature, however, in the makeshifts of his character: the sense of vanity in giving expression to something

original and striking, even at the expense of moral and philosophic sanity. It is the actor masking his clown-visage under cover of tragic mimicry. It is stilted, pompous pose of the consciously inane and wanting; the veneer of imitation spread over a surface of mean and decaying texture. His style and diction forms a commingling of close imitation at once of Byronic "world-pain" and Maeterlinckean mysticism. In the composite features of this mental mold he pours the substance of his own incongruous, aimless and trackless imagination, oscillating between artistic passion for the sensuously beautiful and the moral cynicism of a mind impervious to religious and spiritual infusions.

Failing to receive any guidance from the moral or religious element in life, he naturally also fails to find it in the element of justice. For wherever morality and religion are meaningless, no justice can be appreciated. Hence, his bitter complaint against the injustice dealt him by the world. "Reason," he laments, "tells me that the laws under which I am convicted are wrong and unjust laws, and the system under which I have suffered a wrong and unjust system." If the culprit, however, in his relation to law and justice, can see in himself only a victim and a martyr, his repentance, if he shows any, can hardly represent sincerity of feeling. Moreover, in "*De Profundis*," he declares that "to regret one's own experiences is to arrest one's own development."

Yet, in the chaos of ideas and sentiments, jumbled together in this book of puzzles and mental mosaic, it is hardly possible to determine what sentiments must be taken as a sincere or assumed state of mind of the author. In one breath he speaks of his efforts to "transform the harsh routine of necessity—the degradation of the body into spiritual experience"—while in the next he laments the unreasonableness of destiny, and accuses the "gods of being strange, and punish us for what is good and humane in us as much as for what is evil and perverse." The Goddess of Justice, with her eyes blindfolded, strikes at random, without aim or reason, inflicting punishment on the just, with the same strong indifference as she diffuses prosperity over the wicked.

From Oscar Wilde's point of view the only vital principle of any evolutionary value is contained in art—art, however, divorced from morals. Hence, the groundtone in his mental and moral colorscheme is his realization of being "the symbol of the art of the time," the "typical child of his age," the "central figure in the romantic movement as portrayed on the stage of modern art," with its closing scene in the soul-heaving epilogue of *Reading Goal*—which, to the ill-fated author, stands for the inevitable destiny meted out to all greatness by superstition and ingratitude.

He demands, once for all, to be appreciated and judged, not from a standpoint of morals, but from a standpoint of art. He wants to be seen in the afterglow of romantic twilight, moving gracefully over winding pathways through beauty's bower, wielding the staff of enchantment over the shadow forms of his esthetic creations. It is his love for this aspect of art that inspired him to "throw the pearl of his soul into a cup of wine," and to glide "down the primrose path to the sound of flutes—feasting on the honeycomb of pleasure"—to use his own expressions. And it is in the sphere of art he finds his ideal of Christ. Yet not art in its ethical and moral exaltation, inspiring the devotee to lift his mind in soul-soaring flights towards purer, holier zones of consciousness, but art in its one single and least vital movement—the romantic. And his conception of Christ is certainly very romantic. "Wherever there is a romantic movement in art, there somehow and under some form is Christ. He is in *Romeo* and *Juliet*, in the *Winter's Tale*, in the *Ancient Mariner* and in *La Belle Dame Sans Merci*." And as the romance of life and fiction has its genesis and force in imagination, the author is quite true to his ethical generalizations in affirming that "it is the imaginative quality of Christ's own nature that makes him this palpitating center of romance," and that "out of his own imagination entirely did Jesus of Nazareth create himself" * * * adding, by way of explanation,

that it is "this quality of Christ that makes him so fascinating to artists." As to the historical, the moral, the religious position of Jesus as the spiritual and saving guide through the vicissitudes of human evolution—Jesus, as the incarnation in time and substance of brotherhood, compassion, self-sacrificing love—Oscar Wilde has made no discoveries. Yet he proclaims himself an ardent student of the gospels—"the four prose poems about Christ," and finds them "delightful" reading. His commentaries on the sayings and doings of Jesus are all of the light, frivolous stamp characteristic to sensational journalism. "Christ, like all fascinating personalities, had the power of not merely saying beautiful things himself, but of making other people say beautiful things to him." He fondles with the divine lessons of the great teacher without a touch of reverence or sanctity of feeling. On the contrary, there is an unmistakable presence of cynicism and condescending insolence in his attitude to Christ—the half patronizing, half discountenancing air of high authority, dealing with a gifted but as yet unrecognized aspirant to academical honors.

The author of "*De Profundis*" promises his readers the early publication of a work dealing exclusively with "Christ as the precursor of the romantic movement in life," in which he will show that love has a purely romantic basis, with its sustaining force in personal and social relations. As to the larger, ideal love of brotherhood and humanity uncolored by personalities and sense-life, Oscar Wilde finds it a functionless play of overwrought imagination, without adequate response in human nature. With the one-sidedness of the egotist, he admits of no other motives, instincts or qualities in the world-life than those experienced by himself.

Recognizing himself, *sub rosa*, as unworthy of a great love, he makes the unqualified assertion that "nobody is worthy to be loved," and "that if any love is shown us, we should recognize that we are quite unworthy of it." The only rationale in statements of this character lies in the author's lack of faith in his own deeper nature. Hence, his failure to do justice to his own unvoiced heart. His moral nature is constantly trembling in the balance of power between the intellect and the feeling, the head and the heart. Any overdue estimate bestowed on the sense and intellect categories, detracts from the heart and its deeper emotions. His intellectual inflation reacts in spiritual and moral starvation, and the self-absorption of this gifted but ill-poised writer in his temporal make-up, social stature, sensuous gratification and spectacular impressiveness turns his moral nature into a vacuated hollow mockery, incapable of response to motives of the broader and deeper life of altruism, solidarity and unselfish love.

Recognizing his lack of original intuitions, he took recourse to imitating the mental effusions of writers in which he found these powers present. Hence, the semblance of Maeterlinckean diction in "*De Profundis*." But it is in this appropriation of a phrase, fashioned to serve the subtle logic and mystic depth of Maeterlinck's thought that the egotism and intellectual surface philosophy of Oscar Wilde's literary output receives its inevitable mark of insincerity and cynicism. "Nobody is worthy to be loved," he reiterates in meaningless sensationalism; "if any love is shown us we should recognize that we are quite unworthy of it." "The fact that God loves man shows us that in the divine order of things it is written that eternal love is to be given to what is eternally unworthy."

Having thus reduced the universal love of Christ to a meaningless and uncalled-for quality, Oscar Wilde, by sheer force of logic, is compelled to reduce every super-sensuous attribute of the soul to baseless and substanceless fancies. For it is in love, as a universal, all-embracing force, that every moral sentiment has its root and genesis. Consequently, the author declares boldly that the "morality of Christ was all sympathy," and "his justice a mere poetical justice—exactly," he adds, "what all justice should be." This, of course, gives room for no moral law or order. The relation of man to his universe has no other basis than that of caprice and will-o'-the-wisp. "The beggar goes to heaven because he has been unhappy—and I can not conceive of any better reason for his being sent there."

* * * "Christ knew of no laws * * * while that which is the very keynote of romantic art was to him the proper basis of natural life." * * * "For all lovely influences of life are to him mere modes of light," which, of course, leaves no moral or spiritual basis for the feeling. Or, in other words, that "when dealing with a sinner we find Christ most romantic in the sense of most real."

Thus, by a strange coincidence, Oscar Wilde, in the attitude of Christ to the sinner, discovers the same motives which fall within the color scheme of his own moral adaptations. Through a slight-of-hand maneuver, all its own, the human mind seems capable of reading into its subject any meaning or quality for which it feels a sympathetic leaning. In his "delightful" study of the "four prose poems about Christ," Oscar Wilde gains the sense that "Jesus found sin in itself a beautiful and holy thing, and that his primary desire was not to relieve suffering nor proselytize in saving sinners." "To turn an interesting thief into a tedious, honest man, was not the aim of the Nazarene." That the practical application of such Bible criticism should finally lead to moral and social break-down, was inevitable. Mental balance without moral support is untenable.

The motive back of "*De Profundis*" can hardly be misunderstood. As a moral appeal—a *memento mori*—to a world traveling along the same primrose path of pleasure as did the author himself, and to which he afterwards returned, it utterly failed. The book is focused in personal self-defense—in the ruthless effort of self-justification and restitution from unmerited misfortunes. Reforms in public or private morals, purification through suffering for wrong doings, elevation of the sinner through a life of devotion to duty, the introduction into society of higher standards of life, are not factors in the brief the author serves his moral jurors. "I need not tell you," he exclaims, "that to me reformations in morals are as meaningless and vulgar as reformations in theology." Like the general tendency of our time, which is to live in reflected morals, Oscar Wilde is gauged in his conduct by the fortunes of environments, the rectitude of style, the ethics of the suitable. To gain the sanction of his highly specialized esthetic nature the moral lessons of life must come to him attired in festive robes, accompanied by flutes and symbols. "I could bear a real tragedy if it came to me with purple pall and a mask of noble sorrow." But sorrow, to be a morally cleansing power, must be suffered in silence and humility, not flurried into the flash-light of high-wrought, ostentatious sensationalism, where the energies of the heart are vulgarized by the mind, and the still small voice of conscience muffled up in the clamorous, soul-deadening noises of an over-stimulated, sense-fed ambition with its trail of wounded, revengeful vanities.

These fundamentals of his ethical make-up rise continually into view in this book of his life, "*De Profundis*," imparting to it the leading motives. "People thought it dreadful of me," he laments, "to have entertained at dinner the evil things of life, and to have found pleasure in their company. But then, from the point of view through which I, as an artist in life, approach them, they were delightfully suggestive and stimulating. The danger was half the excitement. * * * My business as an artist was with Ariel. I set myself to wrestle with Caliban." * * *

Absorbed and lost in an altogether exaggerated opinion of his value as judge and law-giver in the world of art and letters, Oscar Wilde turned oblivious to any other mission or object in life than to float as a lotus-eater on the stream of time. After all, however, the only reason and excuse for existence of any man, gifted with genius or not, lies in his power of usefulness in human service. Service of man, unselfishness of motive, and indifference to human plaudits, constitutes the very salt of the earth that keeps the soul from putrefying. For only that which is universal to its aim and character can share the destiny of universal life, and survive. The isolated self-serving motive isolates the individual, and cuts him off from the very circulation in and through which the larger, systematic, imperishable life of the soul is alone made possible.

Selfishness introduces a force in human nature which aims at a dissolution of the nature in which it is found active. Genius, or any degree of mental power, does not save the individual. On the contrary, if not accompanied by noble motives and loving service of man, but spent in personal, self-furthering ambitions, oblivious to the fate of the world, genius, by its very energy and power of momentum, hastens the egotist through the intensity of his self-isolation into inevitable dissolution.

Responsibility, if recognized in principles, but ignored in life, becomes, through a reversion of its dynamic levers, a rentless force of self-destruction. It is one of the greatest of fallacies to regard genius and mental power as redeeming features in the life of a debauchee. His vices, so far from being less deserving of contempt through this association with genius, are rendered only immeasurably more so. No genius, even the greatest, if not accompanied by unselfishness and good will, can atone for one single moral offense. Genius is a faculty, an instrumental possession, but goodness is a power—the *moral will* brought into living action. Genius is a sword—used by selfishness; it threatens other's rights; used by good will, protects them. Hence, the sharper the sword, the keener the genius, the more telling will be its work in one or other direction. The humble citizen, unsolicitous of appreciation or favors, while living up to his conscience and highest sense of duty, does more for the ultimate advance of the human race, and generates a higher individual survival-value, than the sweep of a world-dazzling genius, if the latter be unaccompanied and ungauged by humanizing and unselfish motives.

Medical District Work.

BY OSWALD W. KATZ, M. D.,
Babylon, L. I., New York.

It was on Christmas eve, a district hurry call came in through the telephone, and, dead tired as I was, I took my bag and went out in the misty winter's evening. On a little cot in a Staniford street tenement I found a small girl—the dark eyes wide open—surrounded by the shadows of approaching death, the little white hands clutching an old rag doll. She did not cry, that poor little heap of humanity, but her labored breathing and my examination showed a hopeless case of pneumonia, the very end of it, and there was nothing to be done.

The next building is the Settlement House, and the children sang that old Christmas hymn, "It Came Upon the Midnight Clear." My little patient listened to the soft tones, her face showed the peace that passeth all understanding, and soon she went to the land where there is no sorrow, no heartache.

I went out in the cold winter's evening, wending my way through the happy home-going crowds, and in my ears rang again and again: "It Came Upon the Midnight Clear."

This is not a story, it is just the heart-breaking account of an ignorant, poor family, who did not have enough money to get a doctor, and were too proud to seek charity until too late. You to whom this land has given wealth and riches, you worry about what you are going to wear at Mrs. So-and-So's reception, and your sister, way down in her dark and airless tenement—your sister looks upon her dying child and prays that God—the same God who gave you your wealth—shall save her child. There is no doubt that you send every year a check to the charity, and the Jewish charity organization waits until an application for help comes in, and then starts to investigate, but you know that our people do not beg, they suffer and suffer, and die. We stand upon the holy soil of a country who gave you and me the divine right to do as we please; but to do right, and we owe a great debt to this country for the liberty no other land will give us, and to pay that debt we must see that those who are of our religion shall be provided for.

The physician who does the district work among the poor will tell you that nine out of ten fatal cases are due to the gross ignorance, or well-known indifference of the people; but then the facilities to get a physician are not so easy as you think. If the patient goes to a dispensary

he must stop his work for the time being, must wait hours and hours, and then be the subject of a general examination of students; if he goes to the district mission, a student will come to see him, and he will get the benefit of that student's knowledge and experience. So the only way out of it is to employ graduate physicians, exclusively, for the work. Of course it is essential that the doctor who takes this work shall not do it for mere experience sake; his highest ambition should be to do good, to be not only a physician, but a friend and adviser to those who demand his services.

A few months ago—on the day of a big blizzard—a pale-faced little nurse left the hospital, and with her heavy emergency bag, she fought her way through snow and storm until every call on her list was made. Only a few days later the same nurse occupied a bed in the ward, and there she fought again a fight of life and death through a pneumonia crisis. I passed the ward at night, and in the dim light I could see her sister nurse standing at the bedside of that little heroine, one hand on the lever of the oxygen tank and the other on her patient's pulse. So she stood the whole night, watching for that spark of life, that spark that was in danger of being extinguished forever, in her service as a district nurse. Those are the silent heroes of our noble profession, of whom you do not hear in song and word, but who will sacrifice their lives for the sake of suffering humanity—for the sake of duty. You will hardly understand the battle against infection, etc., those girls have to fight, but the physician who finds that silent watcher on the bedside of his patient knows that it is not always he who saves the patient's life, but the women in blue, who, in the dark hours of danger, stand and fight with their patients to conquer death.

There is a crying need for district physicians and nurses in this settlement, for the cosmopolitan sections. Doctors and nurses should be employed who speak at least German, so that they may feel at home with their patients, and make those people feel that they are understood. As for you—you may do a whole lot of good with your contributions, but you ought to take an active interest in the work, because it is our people who suffer, and the world points at you in some sad occurrences, and says: "Why do not those well-to-do Jews help them?" They know that our people do not burden the community for support, and one single case will produce more prejudice than anything. Do not call it charity, but it is your duty to see that the people of our religion shall not be free patients in hospitals; it is your duty to see that no pauper grave shall close over a Jewish body, and that those who are sick shall have the services of a doctor and nurse employed by you.

This paper is not an oration or literary creation. I do not profess to be one or the other. In the short time of my citizenship I tried my best to pay my gratitude to this country in being a good citizen, and I think I have succeeded. It was a few days ago, at 5:30 A. M., that I wrote this paper. From my little office in the hospital I could see the Star-Spangled Banner over the Armory, that glorious old flag that has given you and me the liberty of this, our country, and I feel that I should stand up in a silent salute for our flag, the flag of our country, the United States of America.

The Treatment of Entero-Colitis.

BY ROBERT C. KENNER, A. M., M. D.,
Louisville, Ky.

The return of summer will not fail to be marked by the prevalence, to a greater or less extent, of entero-colitis. In fact, the disease has come to be regarded as the scourge of this season, and to it is charged the greatest percentage of infant mortality. There should be an intelligent effort put forth in all instances to prevent the development of entero-colitis. This is best carried out in proper feeding, and sustaining the vital forces of infants. A properly fed, well-nourished child is not so vulnerable, and they escape with no damage—or with only slight attacks—when a feeble infant would be completely overthrown. The main points, then, in the prevention of entero-colitis, are adequate and proper feeding, avoidance of exposure to excessive heat, and other influ-

ences that cripple the resisting powers of the infant.

In either the acute or chronic expressions of entero-colitis, the indications for treatment are practically the same. Of course, after the disease has taken on chronicity, the patient demands more attention, as regards diet, nursing, etc., but the essential problem is the same.

When it is possible these patients should be given a change of residence. Removal from the city to a rural district, where the patient can be given comfort and fresh air, is of the greatest advantage. Unless, however, a well-selected country residence is chosen, often the patient is not assisted, and the very reverse has often been noticed.

The question of feeding, that of giving the patient adequate and proper food, is one that is very important. In fact, it is essential to the successful conduct of the case, and the continuance of life. Children at the breast rarely need any alteration of diet, unless it be found that the breast milk is defective, or that mothers have given them table foods. All of these points and others are to be carefully considered. If the infant has been weaned, then it is necessary to carefully enter into the question of feeding. If it should be that the child has recently been weaned, it is often the wise course to obtain a wet nurse for it, and to attempt, for a season, no other form of nourishment. When it is a question of feeding the child—simply that—we have to decide what means is most suitable.

Various infant foods are valuable. I have found many of them to be oak and rock, as it were, in these cases, but in the last two years I have depended to the greatest extent on goat's milk. This food presents some advantages that I have not been able to obtain from any other means at my command for the proper feeding of infants who have been, for any reason, deprived of their mother's breast. In Germany and on the Continent generally goat's milk is largely used as an infant food. Goat's milk differs in formula less radically from woman's milk than does that of the cow, and it has been taken by a great many infants under my observation. For convenience, I give a general exhibit of the various constituents of milk of the animals on whom dependence is made for assistance when the mother's breast is denied.

COMPOSITION OF MILK OF MAN AND OTHER ANIMALS.

One thousand contain the following ingredients:

	Specific Gravity.	Fluid.	Solids.	Sugar.	Fat.	Casein and Extractives.	Salts.
Woman	1032.67	889.08	110.92	43.64	28.68	39.24	1.36
Cow	1033.38	864.06	135.94	38.03	36.12	55 15	6.64
Ass	1034.57	890.12	109.88	50.46	18.53	35.65	5.24
Goat	1033.53	844.90	155.10	36.91	56.87	55.14	6.18

It will be seen that goat's milk is rich in all those properties that nourish the growing infant. One great advantage to be scored by goat's milk is that it can be obtained fresh at any moment. The goat can be kept close to the house, and can be milked just when the infant is to be fed. This is an immense advantage, and can be secured in no other way so conveniently. The advantage that has been secured to infants under my charge, by the goat, has been inestimable. In this connection it is very important that the goat be fed and housed properly. They must be fed good hay, given water, and good beds, and not allowed to run on the commons and devour the waste, as is often done by goats. This point is so essential that I never fail to bring it home thoroughly to the minds of parents and nurses. Still, I must not fail to say that a small amount of codliver oil, in emulsion, given to these patients, twice daily, greatly aids nutrition.

Now, about the remedial measures. I find that it is necessary to unload the intestinal canal every third day, or every fourth at the farthest. This is accomplished by the administration of castor oil. A drachm of castor oil to a child one year old is often enough, but a larger quantity can be given with impunity, as children bear approximately more of this drug than adults. I usually administer castor oil in emulsion. The following is a favorite formula with me:

℞ Castor Oil ..... ½ ounce.
Oil of Peppermint..... 1 drop.
Mucilage of Acacia, enough to make..... 2 ounces.

M. Sig.: Shake vigorously until emulsified. Give patient a tablespoonful as often as necessary.

After the castor oil has moved the bowels, it is my custom to begin the administration of an intestinal antiseptic and soothing sedative to the intestine. These indications have, in my hands, been fulfilled in salol and subnitrate of bismuth. The following is a formula that I use often. It is calculated for a child eighteen months old:

℞ Subnitrate of Bismuth..... 3 drachms.
Salol.....16 grains.
Peppermint water..... ½ ounce.
Mucilage of Acacia, enough to make..... 3 ounces.

M. Sig.: Shake well, and give a teaspoonful every two, three or four hours as the indications in the case in hand seem to warrant.

It is not wise to continue this remedy uninterruptedly. Even though the movements of the bowels are lessened, we are to give, every third or fourth day, a dose of oil to clear away mucous exhalations and retained feces that would, otherwise, poison the blood stream, and work greatly to the detriment of the patient.

In some cases it will be found necessary to give an opiate, in order to restrain the diarrheal discharge. This can be given hypodermically, in these particular cases, with the greatest advantage. The employment of stimulants is necessary in many cases. I prefer merely diluted French brandy. I have no sugar admixture, since all sweets are to be avoided, as far as possible in this affection, for the reason that they superinduce, in many instances, intestinal fermentation, a thing we are studiously avoiding.

After convalescence is well under way we should put the patient on one of the wines of codliver oil. These remedies possess great value and have the merit of palatability, a feature that must address itself to all practitioners who have had much in hand the treatment of infants.

[Written for the MEDICAL BRIEF.]

Of the Imagination in its Relation to Disease.

BY P. C. SUTPHIN, M. D.,
Canmer, Ky.

In any consideration of the subject of the imagination in its relation to disease, quite a *quaestia vexata* presents itself in determining, at all times, as to the true relation between the two. Not infrequently, for instance, we meet with cases that we regard as mostly or altogether imaginary, but which turn out to be genuine cases of disease; while, on the other hand, we sometimes meet with cases of supposed real disease that prove to be imaginary. I have every now and then, in the course of my practice, met with both of these kinds of cases, and, talking with other physicians on the subject, I found that they had also had a like experience in this line.

Such being the fact, therefore, we have, as just said, quite a "vexed question" confronting us in determining at all times as to the correct diagnosis in such cases, and hence as to the proper treatment of them. I have known it the case, in fact, where both the diagnosis and treatment in some of these cases being incorrect, brought into serious question the professional ability of the attending physician, even leading on this account, sometimes, to his dismissal from the case. I call to mind a case of some years back, that passed from the hands of a physician attending it, who had treated it for hysteria, with no benefit, and who was dismissed from the case, it passing over to the care of another physician, who diagnosed it as an obscure, though genuine case of disease, and treating it, accordingly, in due time effected a cure.

It is thus, therefore, that these errors of diagnosis and treatment occur in these cases; nor is it unnatural that such should be the case, in so many instances, where the predominant symptoms are misleading to such an extent as to make the diagnosis difficult, or it may be, sometimes, even impossible. We may boast, in fact, of our diagnostic acumen, but still there are probably but few physicians of any length of practice, who, at some time, have not had some case in which it was difficult, or it may be impossible to form any ready or certain diagnosis of it. I have known it the case, in fact, where the attending physician, uncertain as to the character of some case he was waiting on, had called in one or two other physicians to help him "untangle" it, with no two of them, however, agreeing as to it, and each presenting a different view of it.

Now, admitting as correct what I have said about these difficulties or errors of

diagnosis in these cases, we have the fact established that they have been more or less common in the field of medicine generally; nor could they be said to detract, as a rule, from the professional ability of the physician, as sometimes unavoidable, even when the greatest care and the best judgment are brought to bear to prevent them. In fact, the imagination may be said to play a more or less prominent part in many cases of disease, whilst a successful play on it often does more good than medicines. In evidence of this, take the number of diseases—or probably we might say supposed diseases—cured *cito et jucunde*, or quickly and agreeably, by the Christian Scientist. These cases may, some of them, have been under the treatment of the "best doctors," and having been thought "serious," or it may be incurable, by the patient or friends, under the ordinary medical treatment, were superstitiously handed over to the Christian Scientist, who, by talk, turning the current of a morbid imagination into a more healthful channel—what was mostly needed—thus soon had the patient "on foot."

Now, these cases are highly illustrative of the close relation existing between the imagination and disease; whilst if we take the many of such cases, primarily or secondarily treated by these so-called scientists, then with these and the many similar cases that would be treated by them, when possible to secure their services, is seen the prominent part the imagination plays in many diseases, not infrequently confusing the diagnosis, or leading to errors, in them.

Speaking of this confusion or error of diagnosis, I am reminded of a case I had some years ago, that for some time was quite a puzzle to me, thinking, as I did, that it was a veritable case of bodily disease, which turned out in the end, however, to be the mere "baseless fabric of a dream," or freak of the imagination. The case was that of a stout, able-bodied farmer, living some three miles from me, who, complaining of his bowels "hurting" him, took to his bed and sent for me to attend him. Going to see him, upon entering his room and approaching his bedside, I asked him as to his complaint, which he informed me was a "constant hurting in the bowels," and this he said he had had for several days, and as it got no better, he thought it best to send for me and have something done for it. I now carefully examined as to his bowels, employing pressure upon the abdomen, so as to fully include these, but found no tenderness anywhere; whilst the tongue was clean, and pulse and temperature were normal. Thinking that there might be some vitiated condition of the contents of the bowels, I left him a hydragogue cathartic to properly cleanse these. When taking my leave, I told him to send for me again if necessary. In some four or five days he sent for me again, informing me, when I saw him, that he was "no better." Now, changing my diagnosis to the supposition that there might be possible "intestinal indigestion," with some probable autotoxic complication, requiring digestives and antiseptics for the correction of these, I put him on this treatment, to be kept up for some days, and, leaving him, told him to send for me again, if need be. This he did some days afterwards. When visiting him I found him still "no better." Now, thinking that there might be some obscure subacute inflammatory condition of the bowels that had eluded my investigation, I put him on a tentative treatment for this. He continued on this some ten days, when he again sent for me; not seeing, as he said, that he had "improved any." Being now—to use a common expression—at the end of my journey as to any further medical treatment of the case, I was about to call for consultation in it, when, having noticed that his pulse and temperature had been normal throughout, with tongue clean and appetite good, I now came to the conclusion that it was for him, rather than myself, to cry out *peccavi*, and so I made bold to tell him that having waited on him for a month, and given the greatest care and most patient investigation to his case, I felt called upon to tell him that he was altogether mistaken in being sick in the way that he supposed he was; that his case really originated from an acute morbid condition of the nervous system acting upon the imagination; that the more he kept it in his thought the

more permanent and of more possible wider spread it might become, and that my advice to him, therefore, would be to get out of bed and resume his work on his farm, and think no more of his case. I scarcely thought that he would agree to this, but the advice seemed to please him in the assurance that he had no such disease as he supposed he had, and so next morning he arose from his bed, donned his "working clothes," went to work on his farm, and continued at it. That ended the case.

This rather *in extenso* account of this case I have given as showing, more fully, the part not infrequently played by the imagination in simulating disease, and in confusing and rendering difficult its diagnosis. It may be said, it is true, that in the case just stated, I ought, in a month's time, to have been able to form a proper diagnosis of it before I did, but following out, as the safest guide, the old Latin adage of *festina lente*, or hasten slowly, in the case of one of an athletic constitution, and supposedly free from such imagination as that exhibited by him. In order to make no mistake in the case I deemed it best, rather than form a hasty, permanent diagnosis of it, to proceed slowly, and wait for developments in it, to determine its true character. And it may be said, *en passant*, that this course might be a profitable one to pursue in many diseases outside of those more especially connected with the imagination, as just named—that is to say, where they are not fully developed as to their true character, the better course to pursue would be to "hasten slowly" as to the diagnosis, with the treatment tentative as the symptoms might call for, and thus continued until a definite and correct diagnosis could be determined on, with its more appropriate treatment. In saying this, I am reminded of two cases that came to my knowledge, now some years ago. The first was a case that an old and leading physician of my acquaintance was called upon to attend, who, seeing the case, pronounced it, without hesitation, a serious case of typhoid fever; duly prescribing for it as such. Returning to see the case a day or two after that, he found the patient thickly "broke out" with measles. The other case was one that another physician, also an acquaintance, and a learned and popular practitioner of experience, was called to take in charge, and in his first visit to his patient—a young man—finding him with a cough and complaining of more or less distress about the lungs, he diagnosed the case as one of broncho-pneumonia, and prescribed for it accordingly. Returning a day or two afterwards to see how his patient was "getting on," he found him, also, as in the first case, just spoken of, thickly "peppered out" with measles.

This, however, as just said, by the way; though in these latter cases, as well as those more especially associated with the imagination, or, as it may be, altogether imaginary, we have furnished us a valuable lesson in the way of being careful at all times in our diagnosis, or in cases where the symptoms are obscure, "mixed" or uncertain, to pursue a course of "masterly inactivity" in the diagnosis, and wait for developments to determine as to its true character.

[Written for the MEDICAL BRIEF.]

Taken by Surprise.

BY SILAS HUBBARD, M. D.,
East Aurora, N. Y.

I have known a number of young physicians to be surprised, in delivering a woman at full term, to find only two or three ounces of amniotic fluid. I have known a number of young physicians to be surprised and alarmed, after delivering the woman of the child, that forthwith in delivering the afterbirth a great, sudden gush of a quart or more of amniotic fluid, stained with blood, occurred, while in reality the uterus was well contracted after the gush. The explanation of it would be that in the last pains which expelled the child, the placenta was detached and stopped up the os uteri, and folds of the membranes retained the amniotic fluid, so that when the placenta was expelled the large quantity of amniotic fluid simultaneously followed, and the uterus contracted.

Book Notices.

WHAT TO DO IN CASES OF POISONING. By William Murrell, M. D., F. R. C. P., Physician to the Westminster Hospital; Lecturer on Clinical Medicine and Joint Lecturer on the Principles and Practice of Medicine; Examiner in Materia Medica in the University of Aberdeen; late Examiner in the Universities of Edinburgh and Glasgow, and to the Royal College of Physicians of London. Tenth edition. London, Eng.: H. K. Lewis, Publisher. Price in America, $1.25..

Even though there are many works on "what to do" in cases of poisoning, we have a work before us that is the peer of them all. A work that has been translated into all foreign languages, because it so fully meets the requirements. DR. Murrell had no personal or pecuniary interest in mind when he used his valuable time to write this work; he did it from a heartfelt interest of the sufferer from drug addictions of whatever nature, whether from evil or innocent intentions. The whole field is covered so completely that nothing more could be added to the subject. It is a work that should be in the hands of every American physician and graduated nurse.

THE STANDARD FAMILY PHYSICIAN. A Practical International Encyclopedia of Medicine and Hygiene, Especially Prepared for the Household. By Professor Carl Reissig, M. D., of Hamburg, Germany, and Smith Ely Jelliffe, A. M., M. D., Ph. D., Professor of Pharmacognosy, Pharmaceutical Department Columbia University; Instructor in Pharmacology and Therapeutics, Medical Department Columbia University; Visiting Neurologist, City Hospital, New York; Associate Editor *New York Medical Journal;* Managing Editor of *Journal of Nervous and Mental Diseases.* With the Assistance of Many American and German Specialists in the Treatment of Diseases and Experts in Medicine and Surgery. In two volumes. New York: Funk and Wagnalls Company. Price, per set, buckram, $15.00; three-quarters morocco, $20.00.

This work is fully illustrated; the illustrations are of such a nature that home reading is not barred. It is the first work of this nature that has the endorsement of the educated men of the profession, such as William T. Bull, M. D., William M. Polk, M. D., LL. D., Lewellyn F. Barker, M. D., L. E. Holt, M. D., Thomas Darlington, M. D., William A. White, M. D., David Webster, M. D., Frank E. Miller, M. D., Hills Cole, M. D., Clarendon Rutherford, M. D., Harry V. Werdeman, M. D., Edgar H. Thornton, M. D., Ph. D., Samuel H. Durgin, M. D., Andrew Wade Morton, M. D., J. Welsey Bovee, M. D., David Todd Gilliam, M. D., E. Edmonston, M. D., William O. Rau, M. D., Hugh Cabot, M. D. When such celebrated men take an interest in a work for the family it is well worthy for family use, and certainly a protection for the physician. This is the first work on the subject matter, for the family, prepared by such an array of celebrated physicians—the best educated men in the profession—and draws the inference that the family should be educated along certain lines, and thus aid the physician in his duties. It is a fact that the better educated the patient the better are the results of treatment.

A MANUAL OF PATHOLOGY. By Guthrie McConnell, M. D., Pathologist to the St. Louis Skin and Cancer Hospital and to St. Luke's Hospital; Bacteriologist to the Missouri State Board of Health; Formerly Assistant Pathologist to the Philadelphia City Hospital. Illustrated. Philadelphia and London: W. B. Saunders Co. Price, $2.50.

This work is written more for the student than the general practitioner, who no doubt has in his library more voluminous volumes on the subject, and if not he certainly should secure some, because he knows that this branch of medical science treats of the modifications of functions and changes in structure caused by disease. All physicians, whether in his student days or as a general practitioner (all practitioners should be students), should have a good work on Pathology.

DICTIONARY OF OPHTHALMIC TERMS. By John Welsh Croskey, M. D., Ophthalmic Surgeon to the Philadelphia Hospital and the George Nugent Home for Baptists; Consulting Ophthalmologist to the Prince of Peace Hospital, Philadelphia. Second Edition. New York: Frederick Boger Publishing Co. Price, pasteboard cover, 25 cents; limp leather, 50 cents.

To a physician practicing where a specialist is not at hand and he is called on to examine the eyes and write a prescription, this book is invaluable.

GILLETTE'S SOCIAL REDEMPTION. A Review of World-Wide Conditions as They Exist To-Day, Offering an Entirely New Suggestion for the Remedy of the Evils They Exhibit. With illustrations and index. By Melvin L. Severy, Author of "Fleur-de-Lis," "The Darrow Enigma," "The Mystery of June 13th," etc. Boston: Herbert B. Turner & Co.

To give an idea as to what this work is we quote the dedication: "To all those who, lighted by the first dawning rays of the newly risen social sense, have renounced the red ethics of the competitive jungle and begun their migration from selfdom to 'otherdom.'" Quintilian says: "While we are examining into everything we sometimes find truth where we least expected it." Thus it is that in this work we find truths that we have not found elsewhere. As Plautus said: "I love truth, and wish to have it always spoken to me—I hate a liar." This work has certainly truthful thoughts, and is worthy a careful reading. The author says the plan of this work is the initial step, is presented to the public in the firm belief that it will, if adopted, do more to eradicate the sufferings of all human kind than any plan hitherto proposed. Neither the inventor of the plan nor the author of this work has any selfish interest in the movement. It is placed before the reader so that he will digest the good points for his guidance in the betterment of the human race. It should be read by all who have faith in anything that will be for the advancement of personality in the human being.

ANESTHETICS AND THEIR ADMINISTRATION. A Text-Book for Medical and Dental Practitioners and Students. By Frederic W. Hewitt, M. V. O., M. A., M. D., Cantab., Anesthetist to His Majesty the King; Physician-Anesthetist to St. George's Hospital; Consulting Anesthetist and Emeritus Lecturer on Anesthetics at the London Hospital; Member of Staff of King Edward VII's Hospital for Officers; late Anesthetist at Charing Cross Hospital, the Royal Dental Hospital of London, the Royal Hospital for Children and Women, and the National Orthopedic Hospital. Third edition, with illustrations. London: Macmillan & Co., Ltd.; New York: The Macmillan Company. Price, $4.00.

More attention has been given to this subject by the examining bodies, and the colleges have given it more attention than formerly; it would, therefore, be a matter of wisdom for all practitioners and students to secure the latest edition of this well-known text-book on the subject, as many changes have been made, especially in relation to the important feature of general anesthesia and the so-called "acid intoxication." This work is a standard authority, and should be at hand at all times.

MATERIA MEDICA AND PHARMACY. By Reynold Webb Wilcox, M. A., M. D., LL. D., Professor of Medicine at the New York Post-Graduate Medical School and Hospital; Consulting Physician to the Nassau Hospital; Visiting Physician to St. Mark's Hospital; Ex-President of the American Therapeutic Society; Fellow of the American Academy of Medicine; Member of the American Medical Association; Vice-Chairman of the Revision Committee of the United States Pharmacopeia, etc. Seventh edition, revised. Philadelphia: P. Blakiston's Son & Co. Price, $2.50.

There are many works published on this subject, but each one seems to be different in some respects. That this work has had a place that is pleasing and instructive would be suggested by a seventh edition—that a work has been sufficiently instructive to create a demand for a seventh edition should be a laudable criterion of its worth. It is well, in purchasing a book, to know that so many of the profession have seen good in it.

HINTS ON THE MANAGEMENT OF THE COMMONER INFECTIONS. By R. W. Marsden, M. D., M. R. C. P., D. P. H., Honorary Physician to the Ancoats Hospital, Manchester; Honorary Assistant Physician to the Manchester Hospital for Consumption; Formerly Medical Superintendent Monsall Fever Hospital, and Clinical Lecturer in Infectious Diseases, Owens College, New York: E. B. Treat & Company. Price, $1.50.

How often a physician is puzzled over the treatment of the common infections! If the trouble is grave and intricate he consults his text-books on the subject to widen his scope, but if the common disturbances he does a whole lot of guessing as to what is best. Sometimes he is puzzled even then, because the trouble is persistent and he asks himself *Why?* This work will refresh his memory on such things and thus lead him into new channels of thought. Read it and you will be benefited.

MORRIS'S HUMAN ANATOMY. A Complete, Systematic Treatise by English and American Authors. Edited by Henry Morris, M. A., and M. B., Lond., F. R. C. S., Eng., President of the Royal College of Surgeons of England; Consulting Surgeon to Middlesex Hospital, London; Honorary Member of the Medical Society of the County of New York; Formerly Chairman of the Court of Examiners of the Royal College of Surgeons; Examiner in Anatomy in the University of Durham, and Examiner in Surgery in the University of London; and J. Playfair McMurrich, A. M., Ph. D., Professor of Anatomy, University of Michigan; Member Association of American Anatomists; Member of Advisory Board Wister Institute of Anatomy, etc. Ten hundred and twenty-five illustrations, three hundred and nineteen printed in colors. Fourth edition, revised and enlarged. In five parts. Parts III, IV and V. Philadelphia: P. Blakiston's Son & Co. Price, Part I, $1.50; Part II, $2.00; Parts III and IV, $1.50 each; Part V, $1.00. Also bound in one volume, cloth, $6.00; leather, $7.00.

The edition, in parts, can be bought separately at the prices named above. To give the reader an idea of the scope of each volume we give a synopsis of the contents: Vol. I, Morphogenesis, Osteology, Articulations. Vol. II, Muscles, Organs of Circulation, including Lymphatics. Vol. III, Nervous System, Organs of Special Sense. Vol. IV, Organs of Digestion, of Voice and Respiration, Urinary and Reproductive Organs, Ductless Glands, Skin and Mammary Glands. Vol. V, Surgical and Topographical Anatomy. This will give the reader a pretty good idea of the scope of this work, and show that this is the only Anatomy that can be secured in parts, or in whole, at the discretion of the purchaser.

VEST POCKET SERIES OF ABSTRACTS OF STANDARD TEXT-BOOKS ON MEDICINE, DENTISTRY AND PHARMACY. Published by Medical Abstract Publishing Co., Pittsburg, Pa. Price, each, $1.00.

These works are flexible vest-pocket editions (can be carried in a vest pocket) for ready reference. They are invaluable to medical students, dental students, pharmacy students, scientific and literary students, college professors, doctors, dentists and nurses. The works already published are: *Anatomy*, by Stewart L. McCurdy, A. M., M. D., Pittsburg; *Physiology and Embryology*, by Frederick A. Rhodes, M. D., Pittsburg; *Chemistry*, by John Inglis, A. B., A. M., M. D., Pueblo, Colo.; *Materia Medica and Therapeutics*, by Charles A. Orr, A. M., M. D., Crafton, Pa.; *Histology and Bacteriology*, by A. B. Wallgren, B. S., M. D. Pittsburg, Pa.; *Surgical and Medical Emergencies*, by Stewart L. McCurdy, A. M., M. D., Pittsburg. There will be in all about eighteen of these vest-pocket editions. They are not intended to take the place of text-books, but to emphasize the essential points in all of them. The student in his final examination will find that a thorough reading of these books will greatly aid him, and after he hangs out his sign it will prove a help to him in his practice. We can not too highly commend them. Four thousand copies of the Anatomy have been sold in one year.

A MANUAL OF SURGERY. For Students and Physicians. By Francis T. Stewart, M. D., Professor of Surgery, Philadelphia Polyclinic; Associate in Surgery, Jefferson Medical College; Surgeon to the Germantown Hospital; Out-Patient Surgeon to the Pennsylvania Hospital. With five hundred and four illustrations. Philadelphia: P. Blakiston's Son & Co. Price, $3.50.

The student and practitioner of today needs an ever-present guide on surgical conditions that is devoid of the verbiage and non-essential features that go to make up a large volume. A work of this size must necessarily be concise, and at the same time as complete as the simple facts can make it. The author has fully accomplished this task, as a casual glance at its pages will fully reveal. There are many original illustrations given which lend worth to any work. We predict for this work a large sale.

OBSTETRICS FOR NURSES. By Joseph B. De Lee, A. M., M. D., Professor of Obstetrics Northwestern University Medical School; Obstetrician to Mercy, Wesley, Provident, Cook County, and Chicago Lying-in Hospitals; Lecturer in the Nurses' Training Schools of same. Second edition, thoroughly revised and enlarged. Philadelphia and London: W. B. Saunders Co. Price $2.50.

We believe the book will be found useful to nurses, medical students and young practitioners, and older physicians can glean many good points from its pages.

Editorial.

Why Physicians Do Not Prescribe United States Pharmacopoeia and National Formulary Preparations.

The author of a paper which recently appeared in the *Alumni Report*, published by the Alumni Association of the Philadelphia College of Pharmacy, says that as a result of the examination of one thousand prescriptions from two of the leading drug stores of Philadelphia, he found that thirty-five per cent contained proprietaries. Mr. Edward Bok, the editor of the *Ladies' Home Journal*, who has taken it upon himself to give instructions to physicians, examined one hundred prescriptions in the same city, forty-two of which contained proprietaries. Mr. John B. Thomas, of Baltimore, according to our author, examined the prescriptions from six sections of his city, five hundred from each section, and found about the same proportion of proprietaries were prescribed in Baltimore as at Philadelphia. Now, why is it that, in spite of a foolish agitation against proprietaries, physicians keep on using them? The answer is plain. They have, by experience, found that they gave satisfactory results. They know them to be uniform, and, having in view the restoration of their patients to health, they, as practical, honest men, use those agents which they think will most certainly secure this end.

The writer of the article to which we have referred deplores the fact that physicians will continue to go on prescribing proprietaries instead of the U. S. P. and N. F. imitations. He says he can not see how educated physicians will insist on using proprietaries when there are nine hundred and fifty-eight official preparations in the Pharmacopœia and four hundred and eighty-six in the National Formulary. Unwittingly, he answers his own question. Without intending to do so, he solves the problem himself. For later on in the same paper, he says that pharmacists, as a class, are ignorant, both of the

Pharmacopœia and the National Formulary. He says:

"Ignorance of the Pharmacopœia and National Formulary is also applicable to the pharmacist.. Within the past week I saw a letter written by one of the leading wholesale and retail drug establishments, in a large city near the center of this enlightened commonwealth, to a pharmacist here in Philadelphia, asking him what Liquor Ceresolis Compositus was and *who prepared it.* Last fall, after the Pharmacopœia had been official for over a year, the chief prescription clerk of one of the leading drug stores of Philadelphia called me on the phone and asked the same questions relative to this preparation. *I could enumerate numerous instances of this kind, but these will suffice.*"

Now, even if doctors *wanted* to use the so-called official preparations exclusively, they would not take the risk of prescribing them if the druggists, even in a city like Philadelphia, who live right in the shadow of the best pharmaceutical college in the world, are so ignorant (as this writer says) as not even to recognize them when they are prescribed. And if they do not know them by *name*, how in the name of heaven can they be depended on to compound them? Physicians are well aware of the deficiencies of the druggists, according to our author, and regret it; and yet they must recognize it as one of the conditions of this commercial age, and the druggists can hardly be blamed for its existence. Why, how can a druggist be expected to know all the numerous official preparations and how to compound them? The fact is, it has reached the point when the medicine sold in the average drug store does not amount to over twenty-five per cent of its total sales. Medicine in a drug store has, indeed, gotten to be a "side line." The bulk of the sales is made up of soda-water, confectionery, toilet articles, stationery, postcards, and thousands of other articles in no way connected with medicine. Under these circumstances it would be folly to expect any one druggist to carry in stock all the drugs contained in the one thousand five hundred official preparations; or, if he carried them all, and kept them in good condition, it would not be practicable for any one man to be able to skillfully compound so many preparations, and especially when the sale in them constitutes so small a proportion of his total business. But our author gives a still stronger reason why physicians can not afford to stick to the official preparations, for he tells us that: "*A large number of pharmacists do not possess a copy of the last Pharmacopœia, and only a small number, comparatively, possess a copy of the third edition of the National Formulary.*"

Now, in the name of common sense, how are they going to compound the preparations named in these books when they have not even in their possession copies of them?

It is this state of affairs in the drug trade, and the consequent inability of the doctors to get their prescriptions compounded accurately and with uniformity, that has caused them to turn to and rely on the ethical proprietaries. These, he *knows*, are always the same; they are besides, prepared nicely and represent the greatest skill in elegant pharmacy, and can always be relied on. And when he finds one that gives good results he sticks to it, and he does not care how much he is criticised for doing so by the officials of the medical societies, for he realizes that they are only making a show of doing something in order to hold their jobs, and to bring them into notoriety.

One Reason Why Physicians Prescribe Proprietaries.

No man stands higher in pharmaceutical circles than Professor Edward Kremers, Dean of the School of Pharmacy of the University of Wisconsin. He can not be suspected of being unfriendly to pharmacy, and what he may say about conditions in that professions may, we think. be accepted as true. From a recent address delivered by him, which we find in the *Southern Druggist*, we make the following extract:

"The druggists who organized the Wisconsin Pharmaceutical Association in 1880 lived in the hope that the next generation of pharmacists would be well educated generally, and possess a good tech-

nical training. But what has been the result? The drug store has become less and less efficient as a training school for pharmacists, and yet how few of our apprentices and clerks seek a college education? The cramming schools, which some of them attend preparatory to the State Board examinations, have no educational or technical value whatever. Aside from the personal advantage that the attendants may successfully pass the examination, they are a positive harm to the individual and an increasing menace to the profession.

"Many of the candidates before the State Board can not write ordinary English; fully as many can not do simple problems in applied arithmetic; still smaller is the number capable of logical thinking. They may be excellent salesmen of toilet articles; they may be able to discuss the latest football news while selling cigars; they may be experts in avoiding the payment of a saloon license, as has been the case with hundreds of druggist-saloonkeepers in Massachusetts, Kansas and other States; *but they are not pharmacists to whom we should like to entrust the lives of our sick relatives and friends.*"

All well-informed physicians know that what Professor Kremers says is true. They know, also, that conditions all over the country are as he says they are in Wisconsin. And, having a regard for their patients, and for their own reputations, they hesitate about sending prescriptions to the drug stores, the proper filling of which require the highest pharmaceutical skill. And this is one of the reason why they use so many of the ethical proprietaries. They know that these latter preparations, as a rule, are uniform, and are compounded of the best and purest drugs, and hence can be relied upon.

The Blind Following of Authority.

Before the British Medical Association, at its recent annual meeting, Dr. W. Hale White delivered an address in which he severely condemned the tendency towards the "blind following of authority," which, it seems, prevails not only in this country but in England also. According to this learned doctor, this unfortunate tendency constitutes the greatest drawback to progress in medical science. He said: "Accept nothing on authority, but look for yourselves, and see if the usual teaching is true; believe nothing you do not see; be skeptical about everything you are told."

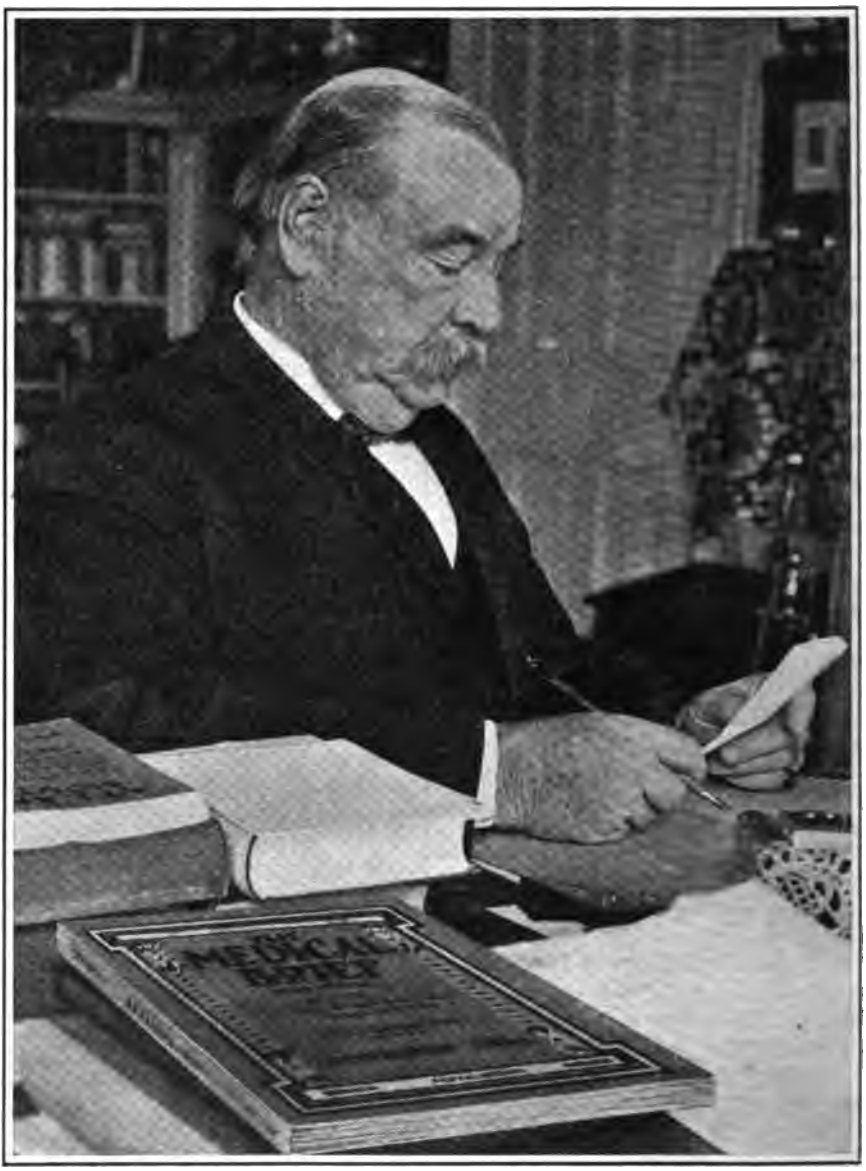
While we are not prepared to go quite as far as Dr. White went, yet it remains that he is correct when he says that the blind following of authority is one of the greatest impediments to progress, and that advancement is possible only to the man who thinks for himself. This does not mean that every announcement from a doctor of distinction is to be met in a spirit of antagonism, but it should not be accepted as true simply because some physician of repute enunciates it. It is entitled, probably, to greater consideration when it comes from a recognized authority, but it should, in all cases, be made to stand the test before it is accepted and acted on. The actual, practical experience of the average doctor is worth more to him than the *ex cathedra* teachings of the physician in authority, however distinguished he may be.

Our minds are given us to think, and unless we exercise our faculties they finally become stunted.

During the past three or four years the physicians of the United States have been treated by a political clique in charge of one of the medical societies as if they were little children. They have been instructed as to how they shall act, and even as to what drugs they shall prescribe, and have been threatened with professional ostracism if they do not comply. Such conduct on the part of a few men in official position has caused a great many physicians to rise in revolt. These physicians realize that the officials referred to are only trying to increase their own power and emoluments, and, like men, they have manifested their resentment at the attempted interference with their liberties as individuals.

The true physician is always looking for light. He is aware that he does not know it all, and, therefore, he is glad to learn from every source. But he refuses to be dictated to by any man or set of men.

the general public. That would be useless as a demonstration, for enough names have been given to show how far short science, medicine, and letters would have fallen durdolle did not mention such famous Englishmen as Lord Nelson, John and Charles Wesley, Lord Tennyson, Dean Stanley, John Keble, Matthew Arnold,



GROVER CLEVELAND, TWICE PRESIDENT OF THE UNITED STATES, SON OF A CLERGYMAN

From a stereograph—copyright, 1906, by Underwood & Underwood, New York

ing the past two centuries but for well-trained and well-educated sons of clergymen.

It would, indeed, be easy to lengthen out the lists. For instance, M. de Candolle and Lord Curzon of Kedleston. He gave no American names save those of Agassiz and Emerson; he might have included Jonathan Edwards, Increase and Cotton Mather, John Han-

(BY PERMISSION OF THE FRANK A. MUNSEY COMPANY.)

A Reader of the Brief.

Among the large number of subscribers to THE MEDICAL BRIEF there are a few lawyers, clergymen, scholars, etc., who have been on our list for a long time, taking the paper, presumably, on account of its editorials, since they can hardly be interested in purely technical medical literature. One of these is Grover Cleveland, the distinguished and universally esteemed ex-President of the United States.

In *Munsey's Magazine* for September, in an article on the Distinguished Sons of Clergymen, is a sketch of Mr. Cleveland, together with a photograph showing the great statesman seated at a table in his library. Before him lies a copy of THE MEDICAL BRIEF, which, evidently, he has just finished reading and laid upon the table.

We have reproduced the page from *Munsey's* herewith, as we thought it might please some of our subscribers to know the distinguished and honorable company they keep. The editor of the BRIEF has always been an admirer of the ex-President, and he only wishes, in these times of unrest, turmoil and agitation, that Mr. Cleveland's conservative and steadying influence could be felt in the counsels of the nation.

Eye Strain.

BY JOHN W. WRIGHT, M. D.,

Professor of Ophthalmology in the Ohio Medical University.
Columbus, Ohio.

Eye strain is at present at high tide. To it are attributed numberless maladies, for not only what is termed the "functional neuroses," but crime, imbecility, incorrigibility and hopeless depravity are often laid at its door. While defective vision may, and doubtless often does, influence the character of the individual, especially in children, eye strain probably does not to a very great extent. However, there should be made a most searching study of both, especially when regarded in the light of affecting not only the physical but the moral condition of the individual.

Eye strain does not usually exist in high degrees of refractive error, for in such cases, if correcting lenses are not applied, the patient can not by accommodative effort sufficiently acquire anything like normal vision. He is, therefore, incapacitated to perform a service requiring good vision; when, if an adult, he is compelled to accept menial avocation that does not require acute vision, and thus he is often associated with those whose companionship might deprave his character.

In the child it is unfortunate if the defect is allowed to go uncorrected, for, not being able to see like other children, school and books are neglected, and if unrestrained it seeks amusement, often in environments not conducive to its moral requirements. For this reason a strict examination of the eyes of all children should be made where there is the least misgiving that there is a defect in the vision. School boards in various parts of the country are doing much to augment this matter and should receive the encouragement of the public.

The symptoms usually attributed to eye strain are so numerous, so varied, so complex and so diffused that were I asked which were the most significant, the answer might well be, *Which* are not?

So far as I know there has been no particular classification of the abnormal concurring conditions which appear with efforts of the accommodation of the eye, that serve definitely to point out their seat. It may be well for us to realize that a great many conditions attributed to eye strain come from other causes, for the functions of the eye may be in a perfectly normal condition, as far as its refraction and accommodation are concerned, yet because of affections of the organs whose nervous connections with the eye are direct or acute, functional efforts of the organ of vision can not be performed without precipitating reflex disturbances of some character or other. In this connection, I would say that I have in my experience often met with cases where no refractive error whatever could be detected, where an effort to read or to perform some work calling for the act of accommodation, would invariably precipitate some annoying neurotic condition. Such cases can

not be corrected with lenses, but require the services, conjointly, of the skilled oculist and physician.

Some of the most prominent recognized symptoms of eye-strain are headache, supraorbital neuralgia, dizziness, chorea, nausea, and insomnia. Sometimes a symptom alights far from the eye.

Some years ago I had under my care a young man who occasionally suffered from lumbago, which was always immediately relieved by the instillation of a mydriatic in each eye. Occasionally we meet with cases of severe pain within the eye, as ophthalmodynia, which, in most cases, is due to cramp or spasm of the ciliary muscle. Relaxation with a mydriatic generally relieves it at once.

Although eye strain from defective refraction of the eye is a frequent cause of this condition, it may be brought about by overwork in the normal eye. Eye strain often is the cause of the symptoms enumerated, and I believe that fully seventy-five per cent of the headaches are due to it.

Fully one-half of the cases of eye strain are due to improperly-fitted glasses. The majority of the people wearing glasses are fitted by so-called refractionists or opticians who know practically nothing of optics or defective eyes. The most severe cases of eye strain are in patients who have little perceptible defect in their refraction, but the constant effort to do near and difficult work causes the obscure nervous conditions. To detect these obscure refractive errors lies within the province of the thoroughly skilled, well-equipped oculists.

The Action of Iron.

BY ELI H. LONG, M. D.,

Professor of Therapeutics, University of Buffalo.
Buffalo, N. Y.

While the more recent experiments and observations in the use of iron have enriched our experience, we can not say that much progress has been made in our knowledge of the precise behavior of this metal in the treatment of chlorosis. The text-book statements of twenty-five years ago regarding the absorption of the inorganic forms of iron, and the therapeutic results of their use, will answer for today with slight modifications. The opinion expressed in 1884 by Bunge to the effect that inorganic iron is not absorbed, but acts simply as a protective to the food iron by uniting with hydrogen sulphide in the intestine, thus saving the food iron from similar combination, leaving it free from absorption, seemed reasonable, and it has had quite an influence in our conception of the action of this metal.

Nevertheless, we can say today that this view has been fully disproved, the proof resting upon two points:

1. The absence of hydrogen sulphide, as a rule, in the small intestine where the absorption of iron is most active, and (2) the experimental work of recent years of Hochhaus, Quincke, Macallum, Honigmann and others, furnishes accumulated evidence that the inorganic forms of iron are freely absorbed from the digestive tract. It seems probable that, whatever form or salt of iron is employed, it is absorbed either as a chloride or an albuminate, chiefly from the duodenum, whence it is deposited in loose combination, chiefly in the liver and spleen, and changed as needed into hematin or hemoglobin or other tissue iron.

Regarding its value in chlorosis there can be no possible question, but it is difficult to understand why the system utilizes the inorganic forms of iron administered, when it seems unable to appropriate the organic forms in which it exists in the food; for chlorotics, as a rule, take foods which are reasonably rich in iron. The question arises whether the inorganic forms are not more easily assimilated. The clinical facts seem to favor this belief. This is not saying that organic forms of iron have no value, because their administration is usually followed by some improvement; but the reported results of several clinicians indicate that the organic forms of iron used today are on the whole inferior to the older inorganic forms, particularly reduced iron, tincture of the chloride and Blaud's pill.

Frontal Band Alopecia or "High Forehead" as a Sign of Graves' Disease and of a Predisposition to Various Vasomotor Troubles of an Apparently Allied Nature.

BY DAVID WALSH, M. D. (EDIN.),
Senior Physician Western Skin Hospital, London; Physician Kensington General Hospital. London, England.

In the title of this article the term Graves' disease has been used in preference to the more familiar name of exophthalmic goitre. The latter name is now generally held to be the less appropriate, inasmuch as it refers to a single sign only in a manifold group, and one that is often conspicuous by its late occurrence or even by its complete abeyance. Amongst British writers the name of Graves has become most generally associated with the disease in question. That distinguished physician described the malady in 1835, and Basedow followed him in 1840, but there is much to be said for the claim of Parry, of Bath, who, in 1825, described eight cases of enlargement of the thyroid gland, in connection with enlargement and palpitation of the heart.

There is no need here to describe in detail the signs and symptoms of Graves' disease. All medical men are, of course, familiar with the symptom—complex picture made up in the early stages chiefly, of tachycardia, tremors, headache, palpitation, exophthalmos, and enlargement of the thyroid gland. To this list it seems not altogether unlikely we may now add a new sign, of extremely common if not of invariable constancy, in the shape of a frontal band alopecia, which is, so far as I have been able to ascertain, usually of congenital origin. As a further observation, after examining a number of persons having a congenital frontal area of practical or complete baldness, I find it invariably associated with one or more of the symptoms that are met with in Graves' disease. In some of these patients the condition or predisposition has actually merged into actual Graves' disease. I therefore am inclined to look upon patients having a congenital frontal bald or semi-bald band area as persons predisposed to the development of Graves' disease, or as being, in other words, the subject of what I have ventured to speak of as "potential" Graves' disease.

The term, frontal band alopecia, is used here to include an area of partial or complete baldness, extending over the frontal margin of the scalp to a breadth of about half an inch or an inch. At each outer end of this frontal band two extensions, or bays, run backwards into the scalp. This frontal band, as already stated, may be hairless, it may be indicated by a narrow pencil of short hairs indicating where, under usual conditions, the anterior margin of the scalp would have reached; or, lastly, it may be covered with a sparse

growth of hair on one or both sides. Where this sparse growth consists of long hairs it is always possible to detect the presence of a frontal band alopecia area by its relative thinness of growth compared with that of the neighboring scalp. This frontal band alopecia is congenital, and its margin, on the scalp side, is less sharply defined than that of the acquired band alopecia, the margin of which is sharp, as though the hair had been shaved off with a razor. In some of my cases it looked as if the acquired sharp edge had been superseded to the congenital form. Where the congenital band alopecia is complicated with ordinary seborrheic baldness it is in some cases difficult or impossible to recognize the existence of the congenital form.

Frontal band alopecia, as a matter of fact, corresponds with the state of affairs known in ordinary life as a "high forehead." The congenital form may, as a rule, be identified by asking whether the patient always had a high forehead. In some cases, more especially in females, the existence of the frontal area is shown by the central projecting point of hairy scalp, which is often called the "widow's peak." If my observation be correct, the high forehead, or frontal band alopecia, is likely in the future to have an important place in diagnosis, both as a sign of Graves' disease, and, possibly, of more importance, as pointing to a special predisposition towards Graves' disease, and towards a large class of associated vasomotor disturbances, such as epistaxis, some forms of headache, Raynaud's disease, urticaria, chilblains, and other more or less remote symptomatic phenomena.

The starting point of this series of observations began in the noting of a frontal band alopecia in a child brought to the hospital out-patient department. The area of baldness, from its appearance, was clearly congenital, and inquiry of the mother confirmed the fact that the forehead had always been "high." A little further investigation showed that the "high forehead" was an extremely common condition, both among children and among adults, and that it was often hereditary. The clew this afforded led to interesting results, and was pursued with the liveliest interest, inasmuch as the origin of many forms of alopecia, and, above all, that kind known as band alopecia, has been hitherto wrapped in profound mystery.

The occurrence of the congenital frontal band alopecia in several cases of Graves' disease, suggested a more detailed examination of the thyroid gland in children with "high foreheads." It soon became evident that the condition of high forehead was not only extremely common, but was, moreover, associated with a series of well-marked signs and symptoms. In general appearance the children were, as a rule, of quick, neurotic type, often highly nervous or timid, and sometimes tremulous; their hands were frequently red or dusky, and cold to the touch, and they suffered from the cold; the pulse was quick; the thyroid, in many cases, showed a moderate enlargement, and the eyeballs were occasionally prominent. The friends often give a history of "nervousness." On inquiry, other members of the family are often found to be nervous and tremulous, with high foreheads and large throats—sometimes the frontal band alopecia and the large thyroid were to be seen in the mother. The frontal band was far more common in girls than in boys, and in this and other ways suggested that there was some relation between its accompanying phenomena and those of Graves' disease.

The idea thus suggested was strengthened by the appearance at hospital of a patient suffering from Graves' disease. She was one of four sisters, all single and all presenting a remarkable family likeness, and all having come to the hospital on account of falling hair. The patient, A. M., aged thirty-six, came to the hospital in November, 1906, with well-marked fine tremors of hands, moderate exophthalmos, slight thyroid enlargement, and a pulse of one hundred and twenty. The condition of Graves' disease, thus plainly indicated, was noted for the first time in 1906, although the patient had been under treatment, at intervals, since September, 1898. On first coming under observation there was certainly no Graves' disease, but she complained of several patches of baldness, one the size *of a palm*. Under appropriate treatment the hair grew over all the bald patches with the exception of

one small area which first appeared at the age of twenty, and which has never since been covered. The patient had suffered from one attack of rheumatic fever, but the general health was fairly good.

Now, on examination, this patient was found to have a congenital frontal band alopecia. There appeared to be some grounds, therefore, for surmising that a potential condition of Graves' disease had been by some determining influence developed into the fully-fledged malady. No history of fright, shock or other depressing condition was forthcoming. At the very time, fortunately, three other sisters were under treatment for falling hair or bald patches.

The family history was fairly good. Father and mother living; mother had a bald patch on head at twenty years of age, and it is still bald. Two of the sisters have had rheumatic fever. There are two brothers; in one, aged thirty-eight years, the hair is receding from the forehead, but not from that of the other, aged twenty years. All four sisters are nervous, all have quick pulse and tremors, all have frontal band alopecia (in one there is a superadded acquired band, shown by its clear-cut edge), all have more or less enlargement of the thyroid gland. All have had patches of baldness, except one who had an extension of the frontal band alopecia behind the left ear.

E. M., thirty years (one of the four sisters), showed fullness over the thyroid gland. She could not tolerate any pressure, however slight, upon the isthmus. She had always suffered from headaches, usually temporal, but sometimes vertical or occipital. There was moderate exophthalmos, but no "tardy lid." Patient never wears a collar (a common sign of thyroid enlargement or undue sensitiveness). Pulse one hundred and thirty-two; very nervous; well-marked frontal band alopecia.

M. M., aged thirty-four years (another sister), had a frontal band alopecia and a small rounded patch in front and above left ear. Pulse ninety-two; very nervous and irritable, constant frontal headaches, hands white, "dead" at times lately, and suffers from chilblains in winter, thyroid full, lobes enlarged, isthmus extremely sensitive to pressure, and also upper part of lobes. Never wears a collar.

An examination of thirteen cases of Graves' disease showed the constant presence of a frontal band alopecia, which, from its appearance, appeared to be congenital. In some cases the congenital nature was confirmed from the history of a "high forehead" since birth. The constancy of this symptom in this comparatively small group can not, of course, be taken as conclusive. It is an association, however, sufficiently striking to place on record as a stimulous to independent observation on the part of others.

A great deal more might be added of interest as regards the investigation of this congenital sign, of which I have, so far, been unable to find any mention in medical literature; that is to say, in its relation to the signs and symptoms of Graves' disease. The association of patch and universal baldness in myxodema has, of course, been frequently noted. In three cases of myxodema under my own observation, I have found the frontal band alopecia. In all three there were clear signs of existing or pre-existing Graves' disease. In another case of myxodema in a woman, aged sixty-one, there was no frontal band alopecia, neither were there any traces of Graves' disease.

The congenital frontal band alopecia may be present in children who may possess none of the signs and symptoms that I have commonly found in another. A careful examination, however, will often reveal nervousness or a history of epistaxis, or some of the associated phenomena in other members of the family. Assuming, for the purpose of argument, that there is any constant association between the congenital high forehead and the Graves' phenomena, it does not follow that there may be more than one or two present, or that the whole group may be latent. We know that in Graves' it is common to meet with cases in which one or more of the classical signs and symptoms are wanting.

The possible origin of the congenital frontal band alopecia opens up an interesting field of speculation and research. It would be premature, at present, to venture into this part of the subject. At the same time it may be permissible to hint

that the sign is possibly or probably of vasomotor origin. In this connection it is interesting to note that in the series of seventy-two cases of frontal band alopecia, upon which this preliminary note is based, thyroid enlargement has been noted in forty-two, myxodema in four, urticaria factitia in one, Raynaud's disease in two (and a probable history of same in another). In a fair proportion there was a family or personal history of tubercle or syphilis.

The effect of appropriate electrical treatment upon Graves' Disease, if taken at an early or moderately early stage, is striking. Carden published an article on the subject in 1891.* My attention was first drawn to the point some little time ago by my friend, Dr. Arthur Harries, who tells me that, in many instances, cure is not only rapid, but complete and permanent. This I have been able to confirm in several instances, at any rate so far as the immediate cure is concerned. After one application of the battery the patient's nervousness will often disappear as if by magic, the pulse falls considerably, exophthalmos lessens, and the patient experiences great relief. In short, the only treatment I have personally found at all satisfactory in Graves' disease or exophthalmic goitre, is that of the electrical current. When applied for the relief of the nervousness and other phenomena of the condition I have called potential Graves' disease, the results are no less striking and satisfactory. Incidentally the hair may sometimes be induced to grow by the indirect application of the current in the local treatment of the thyroid gland.

The key to a number of more or less remote and obscure vasomotor troubles may, in my opinion, be sometimes found in the frontal band alopecia. When this is the case I have found that a reasonable prospect of relief is afforded by the use of appropriate electrical treatment.

This sign—congenital frontal band alopecia—may or may not ultimately prove to have the clinical and pathological significance which I am inclined to attach to it. Of this, however, I feel confident, if the physician who is called upon to investigate the case of a patient suffering from "nervousness" or from hand tremors, due to no obvious reason, he will do well to look at the forehead for this sign.

FIG. 1.

Conversely, if he find the sign, he will do well to look for the associated phenomena of Graves' disease, and he may, in this way, secure valuable hints in arriving at his diagnosis, and in drawing up a plan of treatment.

Incidentally, a large number of interesting problems are suggested. For instance, one man gets a terrible physical or mental shock and survives with nerves unshaken. Another is faced with a similar experience and develops Graves' disease, epilepsy or insanity. May not the latter have a vulnerable constitution, of which the outward and visible sign is a congenital frontal band alopecia? If my surmise be not altogether unfounded, the high forehead is the more or less constant signal of an inherited instability of the vasomotor system.

The high forehead from birth appears to be, as already stated, an extremely common condition. If that be so, and if it can not be potential Graves' disease, then the latter must be far commoner than is generally supposed. From my experience of the frequency of the phenomena of Graves' disease in association

* *Lancet*, July 1, 1891.

with frontal band alopecia, and from the discovery of cases by following up frontal bands, I am inclined to think that mild cases of Graves' disease are often overlooked in medical practice.

In this brief preliminary note it has been out of the question to mention the migraine, the loss of voice, the depression, dyspepsia, diarrhea, vertigo, vomiting, menorrhagia, and many other symptomatic troubles attributed to hypo-thyroidism.

In a great number I have found the "high forehead" as an associate sign. Irritability of temper is commonly found in the class of patients thus denoted. When a person gets angry and hurt for some trifling and inadequate cause and then is unable to eat, so far as my investigations extend at present, that person will be found to have a congenital frontal band alopecia.

The accompanying photograph (Fig. 1) shows L. M., a girl nine years of age, who came to the hospital complaining of a small patch of alopecia on the crown. She

FIG. 2.

was found to have a well-marked congenital frontal band alopecia, of the frontal kind, covered with a thin, sparse growth of hair. The thyroid gland shows marked enlargement in both lobes, pulse one hundred, hands shake sometimes. This is the sort of patient that, later, under the influence of shock, worry and depressing conditions of environment, would be likely to develop Graves' disease.

The second illustration is one of Graves' disease in a patient who has had a frontal band alopecia from infancy. Y. T., thirty-one, married, four children (the eldest suffers from nervousness and tremors; history of fright by a mouse). Patient complains of nervousness and tremors. Eyes prominent, ring of cornea visible and von Gruepe's sign present. Pulse, one hundred. History of shock some years previously. Epigastric throbbing and moderate enlargement of thyroid gland. Family history fairly good, except that mother died of cancer at forty-nine years of age. Patient has always been in pretty good health, with the exception of headaches and nervousness. Had a severe flooding (ten weeks) after birth of last child. The throat diminished in size and symptoms disappeared rapidly under electrical treatment.

The above patient brought two of her children to the hospital—Daisy T., aged eleven years, had a well-marked congenital frontal band alopecia, deeply pigmented skin, and enlargement of thyroid gland, especially in isthmus, which was lobular. No tremors. Pulse, eighty-nine.

George T., aged seven years, has well-marked congenital frontal band alopecia and a palpable thyroid gland, especially the left lobe. Not a nervous boy, but one of the two remaining children is nervous.

[Written for the MEDICAL BRIEF.]

Notes on Neuralgia.

BY ANGUS CAITHNESS, M. A., M. D.,
Glasgow, Scotland.

I have read Dr. Lennane's article on "Neuralgia and its Treatment," in the June number of THE MEDICAL BRIEF, with much interest. It is suggestive, and above all, it contains prescriptions, which are always of value to the busy physician. My interest in the subject arises from the fact that I have been a sufferer from intermittent right supra-orbital neuralgia for many years. This variety is never syphilitic in origin; often, however, it is

due to an old malarial infection, and I have no doubt that such is the case with me. I know of one or two remedies which, apparently, afford relief in the sense that they modify or cut short the attack, and I have a long list of drugs which have utterly failed. For many years I have kept myself well-posted in the literature of the subject, and I must confess that I am, to a very large extent, a believer in and a follower of the late Dr. Francis E. Anstie. He was a well-known London physician, and died, if I mistake not, in 1874, from septicemia, the result of a *post-mortem* wound. He contributed to medical literature various articles on the subject, some of which appeared in an early volume of *Reynold's System of Medicine.* The disease is difficult of definition, but his short description of it adequately serves the purpose. He says:

Neuralgia may be defined as a disease of the nervous system, manifesting itself by pains, which, in the great majority of cases, are unilateral, and which appear to follow accurately the course of particular nerves, and ramify, sometimes into a few, sometimes into all, the terminal branches of those nerves. These pains are usually sudden in their onset, and of a darting, stabbing, boring or burning character; they are, at first, unattended with any local change, or any general febrile excitement. They are always markedly intermittent, at any rate, at first; the intermissions are sometimes regular and sometimes irregular, the attacks commonly go on increasing in severity on each successive occasion. The intermissions are distinguished by complete, or almost complete, freedom from suffering, and in recent cases the patient appears to be quite well at these times; except that for some short time after the attack the parts through which the painful nerves ramify remain sore, and tender to the touch. In old-standing cases, however, persistent tenderness and other signs of local mischief are apt to be developed in the tissues around the peripheral twigs. Severe neuralgias are usually complicated with secondary affections of other nerves which are intimately connected with those that are the original seat of pain; and in this way congestion of blood vessels, hypersecretion or arrested secretion from glands, inflammation and ulceration of tissues are sometimes brought about.

The classification of neuralgias is difficult, but roughly they may be arranged in groups (1) according to their causation or constitutional condition of the patient, and (2) according to the nerves affected and their anatomical distribution. Neuralgia may be traumatic in origin, or it may be due to some constitutional state, such as syphilis, malaria, saturnism, gout, the poison of rheumatism or the various forms of anemia. It is convenient for the moment to exclude those neuralgic pains due to gross anatomical lesions, such as posterior sclerosis and cerebral tumor. It is also necessary to exclude cases of neuritis which, although closely allied to neuralgia, present distinctive differences. Amongst the commonest varieties of neuralgia regarded from the distribution point of view, are (1) the supra-orbital, (2) the trifacial, commonly known as tic douloureux, (3) the cervico-occipital involving the first four cervical nerves, especially the infra-orbital, (4) the cervico-brachial, and (5) the intercostal.

Anstie, however, recognizes many sub-varieties, notably those which are peculiar to different periods of life. The neuralgias of the middle period of life present some peculiarities. By this period is meant the time included between the twenty-fifth and about the fortieth or forty-fifth year. It is the time of life during which the individual is subjected to the most serious pressure from external influences. The men, if poor, are engaged in the absorbing struggle for existence, and for the maintenance of their families; or, if rich and idle, are immersed in dissipation, or haunted by the mental disgust which is generated by ennui. The women are going through the exhausting process of child-bearing, and supporting the numerous cares of a poor household; or are devoured with anxiety for a certain position in fashionable society for themselves and their children; or, again, they are idle and heart-weary, or condemned to an unnatural celibacy. Very often they are both idle and anxious.

The neuralgia of declining bodily vigor or commencing senility are equally char-

acteristic. The period referred to is that which commences with the first indications of general physical decay, of which the earliest which we can recognize (in persons who are not cut off by special diseases), is, perhaps, the tendency to atheromatous change in the arteries. The first development of this change varies very considerably in date; but whenever it occurs it is a plain warning that a new set of vital conditions has arisen, and, especially notable is its connection with the characters of the neuralgic affections which take their rise after its commencement. The period of declining life is preeminently the time for severe and intractable neuralgias. Comparatively few patients are ever permanently cured who are first attacked with neuralgia after they have entered upon what may be termed the "degenerative" period of existence. The existence of commencing arterial degeneration is the special and most trustworthy sign of the initiation of bodily decay; but this change is often not to be detected in its earliest stage. Something has been done of late, however, to render its diagnosis more easy. Not to dwell upon the phenomenon of the *arcus senilis*, which, though of a certain value, is confessedly only very partially reliable, we may mention the sphygmographic character of the pulse as possessing a real value in deciding the physiological status of the arterial system. There is a well-known form of pulse-curve, square-headed, with marked lengthening of the first or systolic portion of the wave, and with an almost total absence of dicrotism, even when the circulation is rapid, which will often seem to assure us that atheromatous change of the arterial system has commenced, even when the physical characters of inelastic artery are not to be recognized in any of the superficial vessels by the touch of the finger. Indeed, the latter test is, in all cases, far less reliable than the sphygmographic trace, except when the arterial change has proceeded to a very marked degree of development.

To a certain extent the presence or absence of gray hair is of value in deciding whether physiological degeneration has begun. Like the *arcus senilis*, however, this is only reliable when joined with other indications, for it may be a purely local and separate change, having nothing to do with the general vital status of the body. It is not necessary to describe the ordinary symptoms of neuralgia, as this is a subject with which every physician is sufficiently familiar, but I may briefly mention some of the secondary affections which follow in the wake of the disease, especially when of long-standing. The commonest of these is vasomotor paralysis. It is doubtful if neuralgia ever reaches more than a very slight degree without involving more or less of this; for the so-called *points douloureux* are themselves pretty certainly, for the most part, a phenomenon of vasomotor palsy; and the more widely diffused soreness, such as remains in the scalp, for instance, after attacks of pain, even at an earlier stage of trigeminal neuralgia than that in which permanently tender points are formed, are probably entirely due to a temporary skin-congestion. The phenomenon presents itself in a much more striking way in the condition of the conjunctiva seen in intense attacks of neuralgia affecting the ocular and peri-ocular branches of the fifth; indeed, the whole conjunctiva is often deeply crimson. Again a more than usually violent attack of sciatic pain is often followed by the development of a pale, rosy blush over the thinner parts of the skin of the leg, especially of the calf. Not merely the circulation, however, but the nutrition of tissues becomes positively affected in a considerable number of cases. It is difficult to judge, with any exactness, in what proportion of neuralgic cases this occurs, but its slighter degrees must be very common. Probably the change is, more usually than not, sub-inflammatory, but it is certain, on the other hand, that there are great variations in the kind of tissue changes complicating neuralgia and that inflammation is no necessary element in them. The hair has changed in color, in many cases. The amount varies from mere patches to gray near the roots of the hair to decided grayness of the majority of the hairs over the larger part of half the head, nearly to the vertex; but in each case it is a change of color that does not exist on the other side of the head. A remarkable phenomenon is fluctuation of

the color, the grayness notably increasing during and for some time after an acute attack of pain, and the same hairs returning afterwards more or less to their original color. Changes in the size and texture of the hairs, in neuralgia, has been noted by Romberg and Notta. Occasionally the individual hairs near the distribution of the painful nerve become coarsely hypertrophied; at times the number of hairs appears to multiply, but this is only a case of more rapid and exuberant development of hairs that would otherwise be weak and small. More commonly the effect of neuralgia upon hair is to make it brittle, and to cause it to fall out in considerable quantities. The periosteum of bone and the fibrous fasciæ in the neighborhood of the painful points of neuralgic nerves not unfrequently take on a condition of sub-acute inflammation, with marked thickening and tenderness on pressure.

A very important point to be noted in connection with the sub-inflammatory swellings of neuralgia is that pressure on them will frequently not merely excite the neuralgic pains in the branches of the affected nerve, but send a powerful reflex influence through the cord to distant organs, causing vomiting, for instance, or affecting the action of the heart in a very perceptible manner. The nutrition of the skin over neuralgic nerves is sometimes notably affected, even when the process does not reach the truly inflammatory stage. The mucous membranes, in situations where we can observe them, not unfrequently show interesting changes, the nutrition of the epithelium of parts covering the painful nerve being exaggerated. It has been noted by various observers, in neuralgia affecting the second and third divisions of the trigeminus, that the half of the tongue corresponding to the painful nerve was covered with a dense fur. This is by no means universally the case. The most familiar of the inflammatory complications of neuralgia is herpes zoster, the favorite seat of which is the skin which covers one or more of the intercostal spaces; the eruption, as occurring in this situation, is so well-known that it would be a waste of time to describe it. In young subjects zoster is commonly painless, at least the sensations are those of heat, pricking and irritation, rather than of acute pain; but from puberty onward there is an increasing tendency, especially in those otherwise predisposed to neuralgia, for zoster to be preceded, accompanied or followed by neuralgia of the intercostal nerves corresponding to the distribution of the eruption. Most commonly, the eruptive period is nearly or quite free from neuralgia, but it often recurs, or breaks out for the first time, when the vesicles are drying up, but more especially if, as is sometimes the case, especially in elderly people, the scabs fall off and leave superficial ulcers. Neuralgia may last, after herpes zoster, for any time from a few days to many weeks. In spite of sundry objections that have been raised to the theory of the nervous origin of zoster, the evidence in favor of it is overwhelming, especially now that it is proved that the disease, with all the same characteristics presented by it when seen on the chest or abdomen, may occur on the face (following the branches of the trigeminus), or on the forearm (following the course of nerves from the brachial plexus). A more formidable occasional complication of neuralgia is inflammation affecting the eye. Jonathan Hutchinson records several cases in which neuralgic herpes zoster of the face was attended with iritis, with serious or even irremediable damage to the organ.

As the object of this paper is practical, rather than theoretical, I will indicate certain modes of treatment I have found useful, although at the risk of repeating the recommendations of previous writers. For supra-orbital neuralgia the best internal remedy is quinine, but to do good it must be given in considerable doses, for example, from thirty to forty grains of the sulphate every six hours during the attack. Of local applications many do good, and I have obtained benefit and relief from aconitine ointment, menthol, thymol, chloral, camphor, belladonna, capsicum, and various combinations of these in solution. The essential oils, such as oil of cajeput, oil of cinnamon, oil of rosemary, oil of cloves, and others which might be mentioned, are distinctly efficacious. A useful local application is the linimentum aconiti compositum, composed of equal parts of the liniments of

aconite, belladonna and chloroform. It must be used with caution, for aconite is an active remedy. Menthol paint, made by dissolving one part of menthol in four of olive oil, often affords relief, and the same may be said of unguentum conii, which consists of conium juice, four ounces, with one and one-half ounces of hydrous wool fat. Cocaine vaseline made by dissolving eight grains of cocaine in an ounce of soft white paraffin, may also be mentioned. When the neuralgia attacks the peripheral nerves counter-irritation is indicated, and this may be applied in the form of some preparation of cantharides which may fall short of actual blistering, mustard, cajeput or hot fomentations. The application of ether, ethylic chloride, chloroform, and various agents of this class, have a distinct sphere of usefulness. Anstie, dwelling on this point, has shown that the external remedies which may be applied for the treatment of neuralgia may be divided into (*a*) skin stimulants, (*b*) paralysers of peripheral sensory nerves, (*c*) remedies adapted to diminish local congestion, (*d*) remedies adapted to diminish arterial pulsation, (*e*) electricity, (*f*) mechanical means of protection.

Among the skin stimulants blisters hold the highest place as a remedy for neuralgia; the assertion of Valleix that they are the best of all remedies, is still not very wide of the truth. They are by no means universally applicable, and the degree to which their action should be carried varies materially in different forms of the disease, but they are of the greatest service in a large number of instances. It is possible to view the action of blisters in neuralgia in more than one way. When applied in such a manner as to vesicate decidedly, and especially if kept open and suppurating for some time they cause considerable pain of a different kind from that of the neuralgia itself, and the mental effect of this, operating as a diversion of the patient's thoughts from his original trouble, may be to assist in breaking the chain of nervous actions by which he is made to feel neuralgic pain.

Another action of blisters which some authors hold to be, perhaps, the most effective portion of their agency, is that which is produced by the drain of fluid, especially when they are kept open, by which means a kind of depletion is set up, and the morbid irritation that causes the nerve-pain removed.

The view which alone explains the beneficial action of blisters, is that which supposes them to act as true stimulants of nerve function. In order that this effect shall be produced, it will be necessary that the skin irritation be either produced at some distance from the seat of the greatest pain, or that, if applied in that spot, it shall be comparatively mild in degree. This object is accomplished by placing the blister as close as may be to the intervertebral foramen from which the painful nerve issues; the effect of this is probably a stimulation of the superficial posterior branches, which is carried inwards to the central nucleus of the nerve.

There are curious differences between the effects of blistering in trigeminal or intercostal neuralgia and in sciatica. It would appear that blistering in the neighborhood of the spine is less frequently effective in the latter, and we sometimes, after failing with this method, obtain immediate success by two or three repetitions of the flying blister, somewhere over the trunk of the nerve, especially just outside the sciatic notch.

It must be said of blistering that it is a remedy not well fitted to be applied to aged subjects; and in its severer forms it should never be applied to patients who are greatly prostrated in strength. For it must be borne in mind that the remedy may miss its aim of relieving the neuralgia, in which case it is necessary to remember, more accurately than many practitioners appear to do, what a very serious element of misery and prostration will be introduced into the case by the vesication itself.

Of the remedies for neuralgia intended for internal administration, quinine is certainly the most generally useful, but I can also speak highly of gelsemium, butyl-chloral-hydrate, chloride of ammonium, and of arsenic. Of the coal tar group my experience has been less favorable, and I think they are better adapted for sick headache of the migrainous type than for actual nerve pain. Guarana and

citrate of caffeine, during the height of a paroxysm, will occasionally afford relief. Nitro-glycerin, in many cases, acts with admirable promptness.

It may be noted that Albert Robin, in a recent article in the *Bulletin gén de Therapeutique*, recommends a mixture of pyramidon, exalgine and Dover's powder. He also uses a syrup having the following somewhat complex composition:

℞ Pyramedon	1½	drachms.
Ammon. Brom.	3	drachms.
Ammon. Iodidi	3	drachms.
Spartein Sulph.	3	grains.
Cocaine Hydroch.	3	grains.
Caffein Valerian	15	grains.
Syrup Aurantii	6	ounces.

M. Sig.: One-half ounce t. d. s.

These complicated prescriptions are not, as a rule, to be recommended, and this is certainly a curious example of poly-pharmacy.

Robin also recommends the following pill, which is comparatively simple:

℞ Ext. Stramonii	1/6	grain.
Ext. Belladoni	1/6	grain.
Ext. Hyoscyami	1/6	grain.

M. Sig.: Ft. pil. One to be taken in the evening and the other at bedtime.

It may be pointed out that the objection to this prescription is that belladonna, hyoscyamus and stramonium have practically the same action.

In many cases of neuralgia the benefit of accessory measures such as attention to diet, clothing, exercise and mental occupation, can not be overlooked. With regard to diet, a plentiful allowance of meat, fish and vegetables is indicated, for in a large proportion of cases, the neuralgic patient is underfed, and consequently anemic. When the body weight is below the normal, fatty food is useful, and this may be supplied in the form of cod-liver oil, glucose, sugar, extract of malt, and, above all, milk, butter and cream. Neuralgic patients are susceptible to the action of cold, and especially of draughts, and both winter and summer they should wear woolen clothing next to the skin. It is better that they should be kept warm by appropriate underclothing rather than by a heavy overcoat, which hampers their movements and prevents them from taking active exercise. I always advise neuralgic people to take a brisk walk, preferably in the early morning, even before breakfast. It improves the appetite and stimulates the circulation. The mind, too, must be occupied, for the indolent are apt to dwell on their pains and physical discomforts. Bright sunlight is a powerful therapeutical agent, and both bedroom and sitting-room should face the sun. A heavy clay soil is bad for all neuralgics, and the house should be dry, and on a sandy or gravel soil. The desideratum for all neuralgic affections is perpetual summer, but this can only be obtained, and it is not always possible, by an annual migration. A bracing air, with a fairly high altitude, is good, but to this rule there are exceptions, for many chronic cases do best, and are freer from pain, in a moist, warm and even relaxing climate.

From this it will be seen that the treatment of neuralgia is a somewhat complex problem, and that many factors have to be taken into consideration.

[Written for the MEDICAL BRIEF.]

An Investigation Into the Modes of Action of the Group of Antiseptics.

BY C. D. F. PHILLIPS, M. D., LL. D. (EDIN.); LL. D. (ABERDEEN); F. R. S. ED., M. R. C. P. (LONDON.)

Late Lecturer on Materia Medica at the Westminster Hospital, London, and Examiner in the Universities of Aberdeen. Glasgow and Edinburgh. London, England.

I.

In this paper it is not proposed to deal with the relative value of different antiseptics, a subject on which there must of necessity be much difference of opinion, but to discuss generally the mode of action of a well recognized group of therapeutical agents.

The etiology of disease having been practically revolutionized during the last few decades by the rapid advances made in pathological research by Koch, Pasteur and others, and the "germ theory" having been established as the true explanation, not only of putrefactive or septic changes, but also of many specific forms of disease —these two facts have naturally directed therapeutists to look for assistance in the treatment of such morbid conditions by

means of the remedies known as antiseptics or germicides.

This large group embraces all those chemical and physical agents which can exert a detrimental or deterrent effect upon the growth and development of micro-organisms, and can bring about their ultimate disintegration.

The value of many of the antiseptics has for long, been recognized, and although their employment has been entirely empirical, their efficacy has been none the less marked or appreciated. Recently, however, large additions have been made to our knowledge of the more special characteristics of this extensive class, and since fresh methods of observation have been introduced and elaborated, more exact researches have been conducted with the view of throwing fresh light upon the manner in which these substances effect their germicide action.

Our knowledge construing them is as yet vague and fragmentary, and the therapeutist, in directing his attention to their study, is met at the commencement by a series of important problems which it will be necessary here shortly to discuss under the following heads:

1. What is known regarding the biological history of microbe or micro-organisms as a class.

2. What is known regarding the action of the microbes upon the tissues as well as upon the great physiological processes of the body itself, whether in a normal or abnormal state.

3. What is known regarding the action of those physical or chemical reagents which are called germicides upon the organisms themselves..

4. What is known regarding the action of germicides whether exhibited externally or internally upon the tissues and functions of the body itself.

1. In considering the first problem, as it presents itself before us here, only a brief review of the ascertained facts can be submitted.

Although numerous and valuable results have been gathered from the careful exertions of many reliable observers (who have devoted much time to the study of the life-history and special characteristics of these micro-organisms, as well as to the differentiation of the individual members of the vast phalanx of which they consist into groups and families)—the difficulties of making a suitable and satisfactory classification are extremely great.

One group of germs (saccharomyces cerevisiæ), are seen to luxuriate, where another (bacillus anthracis) will not be able to show any signs of vital activity, and upon some such peculiarity methods of classification have been adopted.

Pasteur suggested one based upon the necessity (or the reverse) of the presence of oxygen in the surrounding media; and he accordingly divided all germs into two great classes: The ærobic—those which require the presence of oxygen—and the anærobic—those which can flourish without oxygen. For the present purpose, however, such a system of classification is of no value. A more satisfactory basis has been offered by pathologists, who classify germs according to the physiological effects they can produce upon the system of more highly organized beings, into two great divisions, the putrefactive or septic, and the pathogenic or specific.

The latter, the pathogenic, are those that act upon animals so as to produce special forms of disease; they do not flourish in acid media, nor in the absence of proteids and certain inorganic salts; whereas the former exert no specific influence upon the body, and do thrive in acid media, as well as in the absence of proteids. This classification is not quite satisfactory, however, since septic organisms do, in some instances, thrive in alkaline media also, and sometimes vary in their reactions.

For instance, a bacillus supposed to be that of leprosy, although resistant to acids (in staining) when grown in gelatine and bouillon, loses this resistant power when grown on agar-agar.

Certain conditions are now recognized as being essential to such an environment as will allow of the development, growth and multiplication of micro-organisms. Thus they must be situated in a suitable soil, from which the necessary nourishment may be obtained for their subsistence; they must enjoy certain ranges of temperature, and lastly, there must be a certain amount of moisture in the sur-

rounding media. The deprivation of one or all of these conditions, or, in the case of some (as will afterwards be discussed), their presence in excess will arrest the growth and development, or if carried further, bring about the degeneration, and ultimately the complete disintegration of the organisms themselves.

Their growth and multiplication, when placed in a suitable soil, and under favorable conditions, is extremely rapid, and the media soon become teeming with the microbes, but it is an interesting fact to observe that there comes a time when, in spite of the favorable conditions for growth, and regardless of the remains of undevoured stores of nourishment, they degenerate and die; they are no longer able to proliferate, and they become not dormant, but extinct.

Wernich, Burdon, Sanderson and others established the fact in regard to putrefactive ferments that certain complex chemical compounds are produced as the result of their vital action; and that these substances, which mostly belong to the aromatic series, have, when produced in sufficient quantity, themselves a powerful deterrent and destructive effect upon the vital activity of the organisms which have produced them, and thus, by their own increased growth and multiplication, their own destruction is brought about. Koch and others have given greater prominence to those products in relation to pathogenic organisms of tubercle and ague, and considerable light has been thrown upon the etiology of these diseases by such observations.

Again, the chemical compounds produced by one species of micro-organism are often baneful in their effects upon those of another species, so that the appearance of one kind of organism in a cultivation of another may keep, during its presence there, the original growth in check, or even destroy it. This peculiar effect is due, in all probability, to the antiseptic action of the ptomaine produced, being more marked upon the *foreign* germ than upon itself, but considerably more information is needed to supplement our knowledge in this important detail.

A fact even more interesting and remarkable is recorded by Brieger and Fraenkel with reference to diphtheritic bacilli, viz., that they produce two substances, one *toxic* to an animal, the other *protective;* the former destructible by a temperature of 55°-60° C.—the latter resisting a temperature little below boiling point. These substances are otherwise closely allied, and possibly one is transformable into the other.

2. The relation between the micro-organisms and the tissues of the body in which they are found affords a very interesting study, and is a necessary factor for consideration.

That germs are found in enormous numbers in the blood and in the tissues of the body in some specific diseases is an indisputable fact, but the exact relation that they bear to each other is not well known.

Virchow has pointed out that there appears to be a perpetual warfare going on between the micro-organisms and the cells of the tissues with which they come in contact. The microbes attack the cells in their immediate neighborhood, and the cells, in their turn, react upon the microbes and cause their disintegration, and thus an antagonistic process is being carried on between the two with a continuous struggle for the ascendancy. The result of this process is the formation of ptomaines similar in character to those already described as formed in pure cultures apart from the body altogether, but differing, apparently, in the case of different organisms.

Thus, where these microbes become situated (and some appear to affect one organ while another group infect another), considerable local irritation is set up with its concomitant processes, but how the great symptomatic changes are brought about which are regarded as indicative of their presence in the system and the precise relationship of the germs to the diseases with which they are associated, is at present not satisfactorily explained.

Several theories have been advanced to afford a possible basis for rational appreciation of their import.

(*a*). Is it that micro-organisms, having once become introduced into the system, find a suitable nidus in the blood and tissues for their development, grow and multiply with such rapidity that they

come to interfere by their *physical* properties with the great physiological functions of the body? or (*b*), Do they, by the vital requirements of such an enormous number, abstract from the tissues and juices of the body those materials which are essential for their growth, and without which, abnormal conditions of so extensive a nature become established? or (*c*), Is it that they are of themselves innocuous, and cause their virulent effect by the chemical metamorphosis over which they preside in the presence of certain complex compounds (but in which they themselves are not influenced), or by some poisonous secretion or excretion emanating from themselves?

This last, the ptomaine hypothesis, in all probability, is the most likely to afford a satisfactory explanation. It is a recognized fact that ptomaines are present wherever there is a manifestation of vital activity by microbes (though how they are formed is not fully appreciated), and, further, other researches have clearly shown the exceedingly toxic nature of their effect upon the general system, since they produce all the effects of severe fever, when introduced into the circulation, even in very small quantities.

3. What is known regarding the action of those physical or chemical reagents which are called germicides upon the organisms themselves?

Concerning the influence of variations of temperature many observations have been made with the result of showing that some kinds of germs, and even different stages of development of the same germs, can resist higher or lower degrees of temperature than others, and in most instances the high degrees of heat are more effective as germicides than the low degrees of cold, for, although the latter do very markedly diminish vital activity, this is only temporary, unless the exposure be prolonged over very considerable periods of time.

External applications of cold have been recommended, in some cases, to diminish the activity of germs in some local affections, but it will readily be seen that, owing to the normal temperature of the body, the application of cold has to be limited to the surface and to localized areas.

The higher degrees of temperature have undoutedly a wider sphere of application, because of both the greater efficacy of their action, and also the greater readiness with which such high temperatures are obtained. Dry heat is not found to be so effectual as heat with moisture, since it appears that this renders the germs more readily affected.

The rise in temperature in cases of fever may be regarded in this connection as a recuperative attempt on the part of nature to hinder the development, and check the further multiplication of the micro-organisms within the system. Koch has clearly shown that a temperature of 105° F. is sufficiently high to check the further development of tubercle bacilli, and that if these bacilli be exposed for three weeks to a temperature of 107° F., they will be killed. He has also found that the bacillus of cholera was prevented from further growth by a temperature of 104° F., and the bacillus of anthrax by one of 109° F.

This elevation of temperature in specific fevers has a close connection with the renewed activity of the colonies of germs within the body, and is generally regarded as due to an increased formation of ptomaines, which, finding their way into the general circulation, react upon the central nervous system, and cause the rise in temperature.

Moreover, the elevation of temperature has a further beneficial action, since the ptomaines produced exert a more deterrent action upon the growth of the microbes in the presence of increased heat. Heat is of great service in sterilizing instruments and purifying air contained in closed vessels, and also solutions which may form suitable nidus for germs, but the high degrees of heat and the prolonged exposure required render its application inconvenient.

In accordance with these experiments, inhalations of hot air, both moist (Krull), and dry (Sormani and de Toma), have been recommended in cases of tubercle in the lung and diphtheria, or the theory that the growth of the microbes will be checked by such temperatures, but it is difficult to follow the arguments advanced by the above named observers, and their conclusions are by no means convincing.

In discussing the large group of chemical substances, the claims of which, to be recognized as germicides, have from time to time been brought prominently forward, it will not be possible to review them at any length, but it is important to understand how they have been tested and how certain conclusions have been reached.

The method of observation first employed to recognize the value and power of an antiseptic was introduced by Koch, and has since been followed by many other observers.

It consists in observing the degree of concentration required for a given substance in order to prevent the development of a particular organism in a suitable nutrient medium.

Active spores of the bacillus anthracis were for that purpose transferred to media to which known quantities of the chemical had been previously added, and the whole placed under favorable conditions for growth. If this growth was hindered, or prevented, the germicide was proved to produce a positive result.

TABLE I.

GROWTH OF ANTHRAX SPORES IN A GELATINE MEDIUM.

Chemical Agent.	Hindered.	Completely Arrested.
Sublimate Solution	1:1,600,000	1:300,000
Oil of Mustard	1: 330,000	1: 55,000
Allyl Alcohol	1: 167,000	1:
Potassium Arsenite	1: 100,000	1:100,000
Thymol	1: 80,000	
Turpentine	1: 75,000	
Hydrocyanic Acid	1: 40,000	1: 8,000
Oil of Peppermint	1: 33,000	
Osmic Acid	1: 6,000	
Oil of Cloves	1: 5,000	
Potash Soap	1: 5,000	1: 1,000
Iodine	1: 5,000	
Salicylic Acid	1: 3,300	1: 1,500
Hydrochloric Acid	1: 2,500	1: 1,700
Camphor	1: 2,500	above 1: 1,250
Eucalyptol	1: 2,500	above 1: 1,000
Borax	1: 2,000	1: 700
Benzoic Acid	1: 2,000	
Potassium Sulphate	1: 2,000	
Bromine	1: 1,500	
Chlorine	1: 1,500	
Potass. Permanganate	1: 1,400	
Boracic Acid	1: 1,250	1: 800
Carbolic Acid	1: 1,250	1: 850
Chloral Hydrate	1: 1,000	1: 400
Quinine	1: 830	1: 625
Calcium Sulphate	1: 350	
Potassium Chloride	1: 350	1:
Sodium Sulphate	1: 250	
Acetic Acid	1: 250	
Sodium Benzoate	1: 200	
Alcohol	1: 100	1: 125
Sodium Chloride	1: 64	

In reviewing these experiments, however valuable, as they indeed are, it must not be concluded that the degree of concentration given is sufficient to produce a complete antiseptic effect. Undoubtedly the growth and further development of the micro-organisms have been prevented for the time being, and although their death *may* have been caused, yet no such conclusion can be arrived at, unless the germs thus exposed to the antiseptic be transplanted into a suitable soil, under conditions favorable for growth if the vitality be not lost.

This method has, accordingly, been modified by Klein and others, who have adopted the plan of first bringing a small quantity of an organism (either in the culture-fluid or upon sterilized silk thread) into contact for a variable time with a relatively large quantity of the chemical agent to be investigated, and then the vitality of the organisms thus treated is tested after various periods of exposure by placing them in a suitable medium and observing if they still possess the power to grow and multiply; and in the case of those organisms which give rise to specific diseases inoculation of suitable animals is made. The advantages of this latter method are obvious, and the accuracy of the results is insured by further cultivation.

Uterine Displacements and How to Manage Them.

BY MARCUS ROSENWASSER, M. D.,

Professor of Diseases of Women Cleveland College of Physicians and Surgeons. Cleveland, Ohio.

Uterine displacements are found in at least one-third of the cases that come for gynecological treatment. They do not always constitute the chief disorder, but are frequently subordinate to other conditions; as pelvic inflammation, tumors, lacerations. Upward, lateral and quite a proportion of posterior displacements are due to peritoneal causes, which constitute the real disease; while downward, and many posterior displacements are largely due to lacerations. It would be of interest to consider the causes of the various displacements as directly bearing on their management, but time will not permit,

nor would I presume to exhaust your patience.

Classification and Principles—Pelvic inflammation, hemorrhage into the pelvis and pelvic tumors generally, cause displacements of the womb. These displacements are secondary to the existing condition, hence require no management, as such. Any forced effort to correct such malposition is not only of no benefit, but may be followed by results far worse than the original disease. We must, therefore, draw the line in the treatment of displacements between those primarily constituting a diseased state and those secondary to other concurrent pelvic diseases. The womb, under the latter conditions, is more or less limited in its physiologic movements; it is a *fixed* womb.

The division of uterine displacements into those which are *fixed* and those which are *movable* has, therefore, a practical basis.

When the *movable* womb is displaced, the organ may be otherwise healthy, and the remaining pelvic viscera may be normal. We call this a *single* displacement.

More often the mobile womb is not only displaced, but also either itself diseased, or its supports are relaxed above, or lacerated below; these complications of a displaced, movable womb constitute a *complicated* displacement.

Although *simple* displacement may not at first cause any symptoms, I regard its correction as a necessary prophylactic measure. Torsion of the broad ligament, which carries the vascular and nerve supply to the uterus and its appendages, must, in time, lead to congestion, infection, increase in weight and further displacement, converting a simple displacement into a complicated one.

Excepting prolapsus, all *complicated* displacements can be transformed into simple ones by first performing the operation needed for the removal of the diseased endometrium, for the repair or the removal of the cervix, and the repair of the vaginal tube. When thus converted, they become subject to the same treatment. Prolapsus, or downward displacement in its minor degrees, may be relieved, but can not be cured by mechanical means. To effect a cure, a suspension or fixation operation must supplement the vaginal plastic work. The same is true with procidentia. Operations for the latter so frequently prove ultimate failures, that I exhaust all efforts for relief by mechanical support before resorting to surgery.

The *fixed* uteri are, almost without exception, secondary to conditions that require opening of the peritoneal cavity, and are, therefore, to be treated as problems by themselves, each according to the conditions prevailing in the pelvis. Treatment by massage and tampon, and final support by pessary may be successful in a few isolated cases. Gestation may occasionally effect absorption of adhesions, and result in cure.

Management—In the management of uterine displacements our patients can, therefore, be grouped into three classes, namely: Cases requiring mechanical support only; cases requiring preliminary minor operations, followed by support, and cases requiring a major operation involving a risk to life, or to the integrity of the abdominal wall.

Although I believe one-third of the abdominal operations at present done for uterine displacement are unnecessary, yet I have no quarrel with those who discard mechanical supports and treat every displacement by suspension or by shortening of the round ligaments. I have a personal repugnance to placing life in jeopardy, however slight the risk, when an absolutely safe though slower method may bring about equally good results.

Replacement and mechanical support, aided by minor operations when necessary, constitute my treatment for all mobile displacements. The operation of suspension, or of shortening the round ligaments, is limited to those cases only in which the means mentioned have failed to cure, and to cases complicated by prolapsus. In cases requiring major operative intervention for other causes, shortening or suspension constitute merely complementary aids in the intrapelvic technique.

Method—As a rule the examination is made within the two weeks intervening between the week preceding and the week following the menstrual priod. The bowels have been moved by a cathartic taken the night before, and the rectum flushed

by an enema on the morning of the appointment. The bladder is empty. The patient is placed in the lithotomy position.

After inspection of the vulva the patient is requested to strain forcibly; any relaxation of either vaginal wall is thus revealed; the finger introduced into the vagina discovers the degree of uterine prolapse. The condition and position of the vaginal portion of the cervix are next noted. The position and mobility of the fundus are then determined, and lastly the relative position of the appendages and of any abnormal contents of the pelvis. These examinations may be further controlled and a differential diagnosis facilitated by the rectal touch. Virgins, nervous or fleshy women, or those suffering with chronic peritonitis may require an anesthetic before a diagnosis can be made.

Before deciding upon a course of procedure the previous history, the general health and the condition of other organs outside of the pelvis are carefully considered. Is there any causal relation between the present complaint and the pelvic lesion? May not some other (possibly incurable) disease render treatment of the pelvic trouble practically nugatory? Only when the relative importance of the displacement has been established does its correction become the object of treatment.

Forward displacements of sufficient gravity to require treatment are comparatively rare. I have seen but few cases of anteversion in which the bladder symptoms were relieved by an anteversion pessary. Temporary relief pending other treatment is all that can be expected. The womb is normally in slight anteflexion; only aggravated cases with marked angle between neck and body require attention. Even among cases of this class I select for correction only those which offer more or less obstruction to free drainage of the cavity; this is made evident by the difficulty of sounding and the acute sensitiveness of the canal. Dilatation and curettement give relief for a few months. I have discarded the use of the stem pessary, as it has not been attended by better results. Pregnancy offers the best prospect of cure. Inasmuch as we are consulted by single women for dysmenorrhea, and by young married women for sterility, anteflexion causing both painful menstruation and sterility, my advice to single women is to get married, and to married women who are sterile to try to become pregnant as soon as possible after curettement; otherwise the condition is likely to recur. In the case of a single woman who was not improved by curettage, a permanent cure was effected after tedious and painful treatment by galvanic electricity, using the negative intrauterine electrode. This was eleven years ago at the time of the electric fad. The girl has been recently married; it will be of interest to know whether the caustic effect of the electrode has destroyed the mucous membrane extensively enough to prevent pregnancy.

Anteflexions in which the womb as a whole is displaced backward, so called "*retrodisplaced anteflexion*," better *retracted antereflexion*, are due to shortened sacral ligaments; if not benefited by dilatation or curettage they can be corrected by intrapelvic surgery. *Retracted anteflexion*, as well as *lateroflexion*, limits the physiologic movements of the womb, hence both these conditions are to be managed according to the principles laid down for the treatment of fixed womb.

There are but few *simple posterior* displacements that can not be at least symptomatically cured by reposition and pessary. Reposition is accomplished by bimanual manipulation; when this can not be done, the sound is used as an aid. "It is introduced through the speculum and held in place by the right hand, while the speculum is being removed over it with the left. The left index finger is then placed into the posterior vault, pushing the fundus upward, while the handle of the sound is being depressed. The vaginal finger thus guards against injury and facilitates the replacement." "(*The uterine sound, its use and abuse.*"—*New York Journal Gynecol.*, December, 1893).

"The purpose of the pessary is to elongate the relaxed vagina by lifting the posterior vault, which, in turn, draws back and holds the cervix in its normal position. Made of hard rubber or celluloid, moulded to fit and worn under supervision, it is clean and safe. The pessaries, as manufactured, are too short in

proportion to their width and sharp pelvic curve. More length, less width and more gentle curve are needed. The patient does not realize the presence of a well-fitting pessary in the vagina, and can continue wearing it for years with perfect comfort. It does not interfere with sexual relations, nor with conception; it causes no dystocia. The time required for cure varies from one month to several years. A daily alkaline douche and removal once in three months, or sooner, on complaint, constitute the necessary care and supervision. In case of pregnancy, the pessary is removed between the fourth and fifth months." (*The Mechanical Treatment of Retrodeviations of the Womb.*"—Transact. Am. Association Obst. and Gynecol., 1901).

The *complications of backward displacements* are, usually, alone or combined: endometritis, subinvolution, cervical and perineal lacerations and prolapse of ovaries. Curettage and repair of the various injuries tend to reduce the weight and size of the womb; reposition and support may ultimately restore elasticity of the ligaments, and aid the ovaries in regaining their normal position. It is for this reason that I am opposed to the simultaneous repair of the pelvic floor and shortening of the ligaments or fixation of the uterus by whatever method. I postpone and limit peritoneal invasion to the few cases that do not, in time, improve after the treatment here outlined. But these minor operations supplemented by a support, are not sufficient when descent complicates posterior displacement. There is then no prospect of restoration of the elasticity of the ligaments, and hence no possibility of ultimate cure by pessary. Under these circumstances a simultaneous suspension operation is clearly indicated.

Downward displacements, complicated by descent of the anterior vaginal wall or of the bladder, still furnish a large percentage of failures, despite the variety of ingenious operations devised to cure them. Whenever I can find a Gehring pessary to fit, and to be borne with comfort, I prefer it to operation. It is more difficult to insert than a retroversion pessary, and must be more closely watched. Its fixed points resting against the sides of the pelvis, there is more danger of causing ulceration. Until I have become acquainted with the local effect of this pessary an examination is made once a month. We are still waiting for some one to devise a better method for the cure of *procidentia* than those hitherto known; each of which has been successful in a single case, or in a group of isolated cases, but none of which have been found universally applicable when proved by the test of time.

Now, a final word as to choice of suspension operation. Shortening of the round ligaments by the Alexander method has been advised for simple retroversion only. With hardly an exception I treat this class of cases by mechanical support. Considering the fact that in performing the Alexander operation the round ligaments may be found weak, that there is a greater possibility of wound infection, resulting in failure of the operation and subsequent development of hernia, I formerly did the utero-suspension operation of Kelly. Since the publication by Tod Gilliam of his "round ligament ventro-suspension," I have found his method both theoretically and practically more satisfactory. The operation is done in all cases of movable womb in which mechanical support has been carefully tried and found insufficient, or impractical; also simultaneously with the vaginal operations for descent of the womb, especially previous to the menopause.

The particular method adopted when the womb is *fixed* depends upon the conditions present in the pelvis; whether these consist of adhesions only, or whether there are diseased viscera, or neoplasms. Whenever the broad ligament is left intact, the Gilliam operation is done. When portions of the broad ligament have been excised, the union of the lateral raw surface of the broad ligament to the corresponding surfaces at the sides of the womb will hold the womb forward without disturbing the round ligaments. When the womb has been amputated, the stumps of the broad ligament are united with the stump of the uterus, thus lifting the vaginal vault to and securing it at a higher level.

Electricity as a Remedial Agent.

BY J. H. STUART, A. M., M. D.,

Professor of Electro-Therapeutics in the Medical Department of Hamline University. Minneapolis, Minn.

The pathological and other abnormal conditions to which electricity in one modality or another is being applied to great advantage as a remedial agent are many, and the number will, doubtless, continue to be increased. It is but a brief period since the use of electricity in medicine covered little more than the faradic (induced), and the galvanic currents, with little regard to polar distinctions. At the present time the electro-therapeutist finds himself required to select modalities with a discrimination comparable to that of the physician in his choice of medicinal agents. Not that electric modalities are as numerous as the drugs of the pharmacopeia, but they are sufficiently numerous and varied in their effects, so far as they have been observed in the brief period of their therapeutic application, to give opportunity for careful consideration in making selection in individual cases.

By the discovery of the Roentgen ray, the d'Arsonval, the Tesla, and the Oudin currents, and the secondary currents peculiar to the static machine, this field of usefulness seems greatly enlarged, and what further shall be discovered in it is undoubtedly more than mere conjecture. Some of the currents peculiar to the static machine, as the well-known Morton wave current, the breeze, and the spark, by their pronounced influence over the modalism of the body, as well as over local disturbances, have well earned their important place in the *medicatrix naturæ*.

Nothing, it is safe to say, so spectacular and alluring as the Roentgen ray was ever discovered in the whole sphere of medicine. From the day of its discovery it has been subjected to the most careful scientific study, and much has been learned about it, but there remains too much in the obscurity of its significant christening to predicate very confidently what shall yet be revealed. Its potency for evil, whilst it betokens its usefulness, is continually to be reckoned with. But the currents of d'Arsonval, of Tesla and of Oudin, designated as the high frequencies or the high potentialities, are marvelous, both in their characteristics and in their capabilities. They are transformations of the secondaries of both the static machine and the Ruhmkoff coil, by which painful, injurious and destructive currents become at once safe, comparatively painless and of very great therapeutic value, so far as they have been considerately used, and, although they are only in their infancy, it can not be otherwise than that they have within them a vast store house of usefulness in the domain of medicine.

[Written for the MEDICAL BRIEF.]

The Abdomen Regionally Considered.

BY W. E. LEWIS, M. D.,

Professor of Descriptive and Practical Anatomy in Miami Medical College; Member of Association of American Anatomists, Etc. Cincinnati, Ohio.

The organs contained within the abdominal cavity are the greater part of the alimentary canal, as the stomach, duodenum, jejunum, ileum and colon, divided arbitrarily into the cecum, ascending, transverse and descending colon, sigmoid flexure and rectum, the liver and pancreas, glandular organs tributary to the alimentary canal, the great ductless gland, the spleen, the urinary system, consisting of the kidneys, upon the summit of which are mounted the suprarenal capsules, the ureters, bladder, and a portion of the urethra, surrounded by the prostate gland in the male. In the female we have also the uterus with its appendages, the fallopian tubes, the ovaries and their ligaments. Normally, these organs bear a definite relation to each other, as well as to the abdominal cavity. The relation of the hollow viscera, as the alimentary canal, uterus and bladder, depend upon their state of distention. The position of the spleen is also modified, under normal physiological conditions. As practically fixed organs, we have the liver, with its gall-bladder, the greater part of the duodenum, pancreas, kidneys,

with the greater portion of their excretory ducts, and the suprarenal glands.

The relation of the abdominal organs to the peritoneum is of vital importance, and its evolution during development is somewhat complex and intricate. Its relation to the various organs at the completion of its evolution is not so difficult of comprehension if we think of them as being primarily retro-peritoneal, and that during development and growth some of them become invaginated, to a greater or less extent, by the peritoneum, and others do not. Following this conception we find that the stomach invaginates itself into the peritoneum, and is practically completely invested by it. Imagine again the liver following the stomach between the same folds, though not directly. The folds between the lesser curvature of the stomach and the tranverse fissure of the liver becoming the gastro-hepatic omentum. The invagination of the liver is arrested before it becomes completely invested, and we have, therefore, its posterior surface maintaining a direct relation to the posterior abdominal wall. What are usually designated as descending and transverse portions of the duodenum maintain their original retroperitoneal position and are there fixed, and are covered only on their anterior and lateral surfaces. The segment of the primitive gut which is to become the ileum and jejunum, grows enormously, and, as its two extremities are practically fixed, we have the convoluted arrangement necessarily invaginated between two folds of the peritoneum, known as the mesentery, which extends obliquely usually from the left side of the body of the second or third lumbar vertebra to the right sacro-iliac articulation. We are now in the immediate neighborhood of the beginning of the large intestine, viz., the cecum, which is found to have insinuated itself to such a degree as to become completely invested by the peritoneum forming the meso-cecum. Passing upward from the cecum to the under surface of the liver we find the ascending colon adherent to the posterior abdominal wall, and invested only laterally and anteriorally by peritoneum. The transverse colon, which extends from the under surface of the liver to the immediate neighborhood of the inferior extremity of the spleen, is found to have left the posterior wall of the abdomen, and in doing so carried through these folds of peritoneum a connection with the posterior wall. This connecting fold of peritoneum is known as the transverse meso-colon. At the splenic flexure the colon is anchored to the inner surface of the lateral abdominal wall by a fold of peritoneum, known as the phrenocolic ligament, upon which rests the inferior extremity of the spleen. The descending colon has, usually, the same relation to the peritoneum as the ascending, though it may have a short mesentery. The sigmoid flexure, sometimes designated pelvic colon, which extends from the margin of the crest of the ilium, on the left side, to the front of the third sacral vertebra, is invaginated into the peritoneum, and has, therefore, a mesentery which allows a considerable degree of mobility. Succeeding the sigmoid flexure is the rectum, which is sometimes subdivided into the rectum proper and the anal canal. The first division of this classification is at first covered by peritoneum at the sides and in front; farther down, in front only, from which it is reflected upon the posterior surface of the bladder, in the male, and the posterior upper one-fifth or one-fourth of the wall of the vagina, in the female, and then on to the posterior surface of the bladder. The anal canal is destitute of any peritoneal investment.

The pancreas retains its original retroperitoneal position. Its posterior surface is, therefore, not covered by peritoneum.

For all practical purposes, the spleen is completely invested by peritoneum.

The relation of the urinary system, including the suprarenals, to the peritoneum, is readily understood if we conceive the kidneys, the ureters and the bladder introduced through the pelvic outlet, the kidneys being carried upward behind the peritoneum to the lumbar region, carrying with them the greater portion of the ureters, the bladder being left, as it were, at the pelvic floor, and, eventually, being invested upon its posterior and lateral surfaces by peritoneum.

The uterus, including its appendages, can also be conceived as introduced through the pelvic outlet between the rectum and bladder, and as they ascend carry a fold of the peritoneum, lining the pelvic floor, which, extending laterally, forms the broad ligaments.

In addition to the foregoing, the abdominal cavity contains the abdominal aorta and its ramifications, the inferior vena cava and its tributaries, the solar hypogastric and pelvic plexuses, with their afferent and efferent nerves. The primary arterial and venous branches, as well as the nerve plexuses, are retroperitoneal.

The foregoing brief description of the relation of the peritoneum to the abdominal contents is intended to emphasize the fact that all the viscera, including the vessels and nerves, are primarily extra-peritoneal. Some remain so, while others become more or less invested by it. The structures which were before referred to as fixed to the posterior abdominal wall, and, therefore, not covered on their posterior surface by the peritoneum, are the posterior surface of the liver, kidneys, ureters and suprarenals, descending and transverse portions of the duodenum, the pancreas, and, usually, the ascending and descending colon and what was denominated as the first part of the rectum. The base of the bladder, prostate gland, as well as the anal canal and a greater portion of the vagina, can also be referred to as extra-peritoneal. These organs can, therefore, be reached without implicating the peritoneum.

In contemplating the anatomy of the pelvic outlet, we are almost persuaded that the Omnipotent had in view what might be termed the physiological pathological conditions incident to senility affecting the bladder, prostate, anal canal or vagina, all of which, as before stated, can be reached without danger to the peritoneum.

The stomach, including the first portion of the duodenum, the small intestine, the transverse and sigmoid colon, the cecum, and rarely the ascending and descending colon, and the spleen, are completely invested by peritoneum. A characteristic of these organs is mobility. The uterus and its appendages also owe their mobility to being completely invested by peritoneum.

I have purposely referred to the contents of the abdominal cavity before considering the cavity itself, as I believe such an order more impressive and intelligent. I will next briefly refresh your memory as to the anatomy of the cavity. Age and sex impress certain characteristics upon it. However, its shape in general is said to be ovoid, its long axis vertical, the extremities being directed upward and downward. The upper limit or roof is concave, and is formed by the under surface of the diaphragm. The floor, also concave, is formed by the levatores ani and coccygei muscles. The posterior wall is formed by the lumbar vertebræ, and if we regard the pelvis as part of the cavity, by the sacrum and coccyx, the crura of the diaphragm, the psoas and quadratus lumborum muscles. The lateral boundaries are the lower six ribs, the diaphragm intervening, the transversalis, the internal and external oblique muscles, and the inner surfaces of the ilium and ischium. The anterior wall is formed by the two oblique, transversalis, and recti muscles and their aponeurotic expansions, and the inner surface of the bodies and rami of the pubes. The whole of the internal surface is lined with a continuous fascia, which receives various names, distinctive of its relation, as lumbar, transversalis, iliac, pelvic, recto-vesical, etc. Posteriorly, the abdominal cavity is greatly encroached upon by the projection forward of the bodies of the vertebræ.

I would especially call attention to the relation of the diaphragm to the cavity. The central portion of the diaphragm is tendinous, and is placed almost horizontally. On the right side, during expiration, the diaphragm ascends to the level of the fourth rib, on the left side to the level of the fifth rib. In this connection I might remind you of the fact that the fibrous layer of the pericardium blends, or, in other words, is attached to the diaphragm by means of ligaments. Above, the pericardium is connected to the deep cervical fascia. This arrangement indirectly connects the tendinous portion of the diaphragm to the cervical portion of

the vertebral column, and thus maintains it in its horizontal elevated position.

As my space is limited, I can only very briefly refer to the medical and surgical sides of the subject, and shall confine my remarks more especially to the anterior wall. For convenience and accuracy when referring to the contents of the abdominal cavity, anatomists have divided it into regions. The limitations of these regions vary somewhat, as different authors select different levels, etc., for indicating on the surface the boundaries. The subdivisions, as adopted by Cunningham, seem the most practical, as the lines are extended between bony eminences. Two horizontal lines are drawn around the trunk, the upper one at the level of the lower border of the tenth costal cartilage, and is designated the subcostal. This is on a level, posteriorly, with the disk between the second and third lumbar vertebræ. The lower line is on a level with the highest point of the iliac crest, as seen from in front. This is about two inches behind the anterior superior spinous process of the ilium, and is designated intertubercular line, as the crest presents at this point on the outer lip a tubercular eminence. This line is on a level, posteriorly, with the middle or upper part of the body of the fifth lumbar vertebra. Vertical lines are drawn upward from Poupart's ligament, midway between the symphysis pubis and the anterior superior iliac spine, and are designated Poupart's lines. They bisect the horizontal lines at right angles. From the various lines imaginary planes extend through the cavity, dividing it into nine regions. The horizontal lines divide the abdomen into three zones, named from above downward, costal, umbilical and hypogastric. A more suggestive name for this zone would be iliac, as the ilei hold the same relation to it as do the costæ to the costal zone, and it is far removed from the stomach; in fact, another zone intervenes. By means of the vertical lines the zones are divided into nine regions, usually designated right and left hypochondriac, epigastric, right and left lumbar, umbilical, right and left iliac, and hypogastric. A more suggestive name for this last region would be suprapubic.

A detailed description of the contents of each region would extend this paper beyond the allotted space, and this must be omitted. Much attention has always been paid to the physical examination of the contents of the thoracic cavity, while the abdominal cavity has only of late years attracted the attention of the more progressive physicians and surgeons, and it has proved a most fruitful field, not only pathologically, but financially as well. To the trained and careful observer the general appearance of the abdominal wall is pregnant with suggestions which invite confirmation by means of palpation and percussion. Engorgement of the superficial veins of the abdomen is suggestive of conditions which obstruct the portal or hepatic circulation. These obstructions may consist of intra-abdominal tumors affecting the stomach or duodenum, enlarged lymphatic glands, especially at the transverse fissure of the liver. Engorgement of these superficial veins may also be due to various pathological conditions of the liver itself, or to a tricuspid insufficiency, which may be manifested by the pulsations of the right ventricle, being transmitted to the inferior vena cava, resulting in an abdominal pulsation simulating an aneurismal throb. The normal rhythmic movements of the abdominal muscles become exaggerated in diseased conditions which interferes with full expansion of the lungs, while the movements are diminished in intra-abdominal conditions, especially of an inflammatory nature accompanied by pain. Retraction of the abdomen is seen in the emaciated, in various cerebral diseases, especially in tubercular meningitis of the young. Enlargement of the abdomen suggests ascites, tumors, hypertrophy of some organ, tympanites, gaseous distention of some segment of the alimentary canal, or pregnancy in the female. Palpation and percussion of the abdominal wall are pregnant with information regarding the condition of its contents. Auscultation detects the bruit of aneurysmal tumors, the gurgling of imprisoned intestine, the fetal heart, and the placental murmur in pregnancy.

Surgically, the abdominal cavity is of paramount importance. Not an organ or

structure within but may require surgery. Some can be reached from behind, thus avoiding injury to the peritoneum. Most operations, though, are from the interior surface. This renders the anatomy of this region of special importance. The character, as well as the physical properties of the wall, are to be taken into consideration. All the muscles of the anterior and lateral abdominal walls can be regarded as having their fixed point below, and attached to some part of the thorax above. Extending vertically from the pubis to the thorax, parallel with each other, are the two recti muscles. Their inner borders are practically in contact below, but as they ascend and, especially above the umbilicus, they diverge, leaving a considerable interval between them, which is occupied by the union of the aponeurosis of the muscles in this situation. A line extending from the ensiform cartilage to the symphysis pubis is the classical linea alba. From a little below the umbilicus there is no depression or groove, as the two recti are in contact through their sheaths, and, besides, this region is, usually, covered with a varying amount of adipose tissue. At the outer border of the recti the aponeurosis of the flat muscles are arranged in such a manner as to form sheaths for them, and here are found the so-called linea semilunares, which are not semilunar. As terms more appropriate and suggestive for these surgical landmarks or areas I would substitute for the linea alba, which is not a white line, linea tendinosæ centralis, as it is tendinous in structure and central in position. For linea semilunaræ, I would substitute linea tendinosæ lateralis. These tendinous lines offer some advantages for incisions into the abdominal cavity. However, the disadvantages as to the future integrity of the incised area outweigh the advantages. Cicatrices in fibrous tissue, owing to its inelasticity, are prone to rupture under pressure. The character of the wall in the iliac regions is similar, especially in the neighborhood of the inguinal canal, and the various operations in this region for hernia are, necessarily, fraught with danger as to the future.

The costal zone has, of recent years, acquired well-merited attention. In this region are to be found the liver, with its excretory apparatus, the stomach, part of the duodenum, and the spleen. What were formerly regarded as various forms of indigestion, gastralgia, bilious attacks, etc., are now, thanks to surgery, known to be of a surgical nature, as ulcer of the stomach or duodenum, malignant disease of these same organs, inflammatory or obstructive conditions of the gall-bladder, the cystic, hepatic or common bile duct. The right half of the costal zone, especially in the neighborhood of the vertebral column, should be thoroughly familiar to the surgeon who contemplates work in this region. Here are found the hepatic flexure of the colon, the duodenum, embracing in its concavity the head of the pancreas, the common bile duct with its tributaries, the kidney, the pelvic expansion of the ureter, the suprarenal capsules, portal vessels and inferior vena cava, all bound, to a varying degree, to each other, and to the vertebral column by areolar tissue.

The brilliant results obtained in the surgery of the upper region of the abdomen by Mayo, have given him well-merited reputation, and I sometimes think we might, with propriety, designate the costal zone as Mayo's zone. We have Scarpa's triangle, Hesselback's triangle, the space of Retzius, the tubes of Fallopius and Eustachius, the ducts of Wirsung and Stenson, the circle of Willis, none of which are, in themselves, indicative of anything anatomical, but serve to perpetuate the memory of distinguished anatomists.

Practical Hints on the Care of the Hair and Scalp.

BY GEORGE WARREN SPENCER, M. D.,

Professor of Physiology and Dermatology in the Cleveland Homeopathic Medical College. Cleveland, Ohio.

For a proper understanding of the care of the hair and scalp it is necessary to consider the anatomy and physiology of the parts. Anatomically, we have a portion of the skin covered with a more or

less thick growth of hair, richly supplied with blood vessels, nerve endings and sebaceous and sweat glands, the latter infinitely more active than in any other portions of the cutaneous surface, and consequently more susceptible to external as well as internal disturbances.

Physiologically, the hair is intended as a protection for the head against injury, changes of temperature, regulation of the degree of moisture, and all the essentials for which we wear clothing on other portions of the body.

Therefore, we must keep in mind these two things in the management and care of the scalp and hair.

As women have, by mere chance, adhered more or less closely to lightly-constructed headgear, permitting abundant ventilation, and as the length and thickness of their hair does not permit of rough and systematic rubbing, the scalp is protected from undue violence. It is in the male, therefore, that we see the marked results of neglect or abuse in the care of the scalp and hair. At an early age the hair of the boy is closely clipped, with the result that the principal function of the hair, protection, is in part, destroyed. Consequently a thick hat or cap must be substituted. This headwear, for the most part, is entirely without ventilation, and the greatest care is exercised in getting a perfect fit, seemingly to keep the life-giving elements from the head. Undue heat accumulates, as there can be no radiation from a tightly closed space. As a result of this undue heat the sweat and sebaceous glands are more active, and moisture accumulates, which macerates the scalp and hair, thus making a good media for the development of disease. Sweat-bands irritate the forehead, and the condition spreads upwards, the effect of which, on the forehead, becoming higher and higher.

As if this were not enough, most men and boys think it necessary to scrub their scalps with soap and water, drying by violent rubbing with a rough towel, or submitting to a shampoo, which leaves the scalp in a tender and congested condition favorable for infection and sensitive to atmospheric changes.

The stiff brush can only be of great injury to the scalp. I can not advise any but the most gentle and antiseptic treatment of the hair and scalp. The only lotion that need be used is pure water and a good soap, washing the scalp carefully with warm or tepid water, and rinsing thoroughly with clean water, and lightly rubbing the hair dry with a towel, or, better still, fanning it dry.

If some disease or disturbance is present, as indicated by slight itching of the scalp, then Hg CL_2 1/2000 can be sparingly used.

Nourishment in Surgical and Medical Cases.

BY FRANK K. WILMETH, M. D.,

Dean of the Lincoln Medical College; Professor of Principles and Practice of Medicine in Same. Lincoln, Neb.

This plan of securing nourishment in surgical and medical cases occurred to me some years ago, during the management of the following case:

A young woman, twenty-seven years old, was admitted to the hospital suffering from a bilateral pyosalpingitis. She had been nauseated and vomited during a period of forty-eight hours, when she was unable to retain any nourishment by the mouth or rectal injection. I operated at once. She was put to bed and about six hours afterward developed symptoms of shock, and appeared in a grave condition. She recognized me when I called to see her, spoke to me, and with a slight shrug of the shoulders commenced to have spasms of the limbs, and became delirious. I decided her condition was due to lack of nourishment. I directed the nurse to bring a four-ounce preparation of beef blood, with eight ounces of normal salt solution, and the infusion injected under the mammary gland on either side. In less than one hour from this I noted the pulse come down rapidly and increase in strength. The patient turned over in bed and asked me when I came in. I immediately retired and the case progressed uninterruptedly. In forty-eight hours from this time she was able to take nourishment by mouth and made an uneventful recovery.

Since that time it has been my custom in all cases where, for any reason, the patient was unable to properly digest food, or the vitality low, to use this preparation subcutaneously with a normal salt solution, varying usually from twenty-five to fifty per cent of the preparation of beef blood. The use of from twenty-five to fifty per cent of this preparation, with normal salt solution, each eight ounces, will sufficiently nourish a patient for twenty-four hours.

This method of feeding will at once commend itself to all physicians as being absolutely as certain as a hypodermic injection of heart stimulant, or any other material that might be used. It nourishes; the nutrient material being absorbed in the circulation if there is sufficient circulation to sustain life for from one to two hours. I have used it in various kinds of medical, as well as surgical cases, and in weak or anemic persons, or those exhausted by long illness, and have found it to be the most successful method of feeding in these cases, with which I am acquainted. This method is not new, having been discussed at various meetings some years ago, but at the time I commenced its use I had not heard that it had ever been used.

If superficial inflammation occurs at the points where injections are made, hot normal salt fomentation will, in nearly all instances, prove sufficient to dispel the inflammation.

1415 N. Street.

[Written for the MEDICAL BRIEF.]

Report of a Case of Gastric Ulcer.

BY CHARLES W. MCGAVRAN, B. SC., M. D.,

Professor of Physical Diagnosis in the Ohio Medical University; Visiting Physician to the Protestant Hospital.
Columbus, Ohio.

A. B., aged twenty-nine, married, railroad conductor by occupation, born in Ohio, presented himself for treatment for "stomach trouble," from which he had suffered for fifteen years.

He gave a history of the usual diseases of childhood, diphtheria at five; claims he was not well since, and was never considered strong as a child. Had an attack of pneumonia in 1894, and another in 1896, the second attack following measles. Both attacks were severe. Typhoid fever in 1905, moderate in severity; duration three weeks. At the age of fourteen patient complained of pain upon lying down. This condition remained until the present, becoming more severe at intervals. For fifteen years he has been unable to sleep in a recumbent posture, requiring from three to four pillows to lift the shoulders. He states that while in this position he is free from pain. Appetite fair, bowels more or less constipated, no vomiting. Stools dark. Presence of food in stomach apparently has no influence over pain. No history of syphilis, family history negative.

Physical Examination.—Patient tall, poorly nourished, anemic in appearance. He is six feet tall and weighs one hundred and thirty-three and one-half pounds; tongue coated. Area of tenderness just to the left of the ensiform appendix. Stomach, when not distended, reached to the level of the umbilicus; when distended it reached about two inches below the umbilicus.

Examination of the gastric contents showed free hydrochloric acid, .65; total acidity, .90. Tests for occult blood were positive, although there was no free hemorrhage on first lavage; during the second examination there was free hemorrhage in the lavage. Stools were dark colored. The guaiac turpentine test showed blood to be present.

Diagnosis of ulcer involving the upper and posterior surface of the lesser curvature.

Treatment consisted of lavage with one ten-thousandths of silver nitrate every third day, giving silver nitrate, one-quarter grain doses, in large quantities of water four times a day. This treatment was followed by an amelioration of all the symptoms. Last examination of gastric contents showed them to be normal, and patient free from pain.

This patient was one of a family of large-sized, healthy men. His brothers shared the same food and lived under the same conditions, and the only reason ascribed by the patient for his failure to gain flesh was the continual pain. There

must be some connection between the pain in the epigastrium and the continued loss of weight. Clinical examination showed free blood in the stomach and occult flow in the stools.

I think the history of this case illustrates the fact that we may have an ulcer at the upper and posterior part of the stomach without pain being increased upon the taking of food. At the same time pain is caused by the patient assuming the dorsal position, permitting the food to come up, the pain being relieved when the patient again assumes the upright position.

A Case of Twenty-Five Convulsions in Twenty-Four Hours, With Recovery.

BY L. F. BARNEY, M. D.,
Assistant Professor of Surgery in the Kansas University.
Kansas City, Kansas.

I was called at 9:30 one night to see a man suffering from convulsions. I was given the following history:

Patient, a man of twenty-three, who was employed as teamster in a nearby packing house. He had worked that day as usual, and on his way home had remarked to a friend that he was feeling particularly well. He had eaten a hearty supper, then had gone to a barber shop, and was shaved. Returning to the house, he acted rather peculiarly in that he seemed cross, but went on upstairs and to bed. Half an hour later a noise was heard in his room, and, on investigation, he was found in a convulsion, which lasted about three minutes. He was in a comatose condition, and an effort was made to lift him into a more comfortable position, when he immediately had another convulsion. I was telephoned for, and found him twenty minutes later in another convulsion. I started to move him, and he had another convulsion, apparently epileptic; he frothed at the mouth; had convulsive movements of the limbs, and had every appearance of epileptic seizures, except, perhaps, that in epilepsy convulsions are not repeated in so short a period. He was given no medicine that night. Next morning I saw him again, with Dr. Palmer, who had also seen him the night before, and he appeared in fair condition. During the night he had five more convulsions. At two o'clock in the afternoon we were called, and found him having convulsions every fifteen minutes. His pulse grew slow, and he appeared to be failing rapidly. I catheterized him, and drew off a small quantity of urine, which I examined for albumen, but found none. While I was making this examination Dr. Palmer called to me that the man was dying. We gave him a hypodermic injection, also a high enema, and he rallied. The prognosis seemed most unfavorable. He had seventeen convulsions between 11:30 and 10:30 that night. We remained until 10:30 at night, until the convulsions had ceased, and returned next morning hardly daring to expect that he would be alive. However, there were no more convulsions during the night, and next day he returned to his home in Atchison, where he remained two weeks and returned here feeling perfectly well.

The question with me is, what was this? Was it a case of uremia?

What Peculiarity is There in Climate That Favors the Growth of Pine Trees, and Does This Peculiarity, Whatever It May Be, Favor the Cure of Consumption?

BY ALBERT S. ASHMEAD, M. D.,
New York City.

Col. F. T., an old soldier of our civil war, was a sufferer from "consumption." In quest of climatic conditions which would be beneficial, or perhaps restore him to health, he had spent a summer up North, on the lakes, one season in Colorado, a year in California, and some time in New Mexico and Texas, besides making several trips East.

The origin of his illness was, it was thought, a gunshot wound, the bullet penetrating the right lung. Thirty years

after receiving the shot he died of consumption. Much of the time he was a confirmed invalid, and read a great deal—among other things all kinds of books and literature bearing on his affliction, so he was fairly-well posted. During the last year of his life he spent much time in poring over statistics of every phase of the disease, especially that relating to mortality, the country or section showing the highest and lowest percentage of deaths from consumption.

From his studies, he became convinced that the pine and turpentine regions of Georgia offered the best inducements for the relief or cure of those afflicted, as he was, with affections of the lungs. Like many others, however, he deferred his visit to Georgia until he was unable to make the trip, and died fully believing health and vigor was in store for him if he could be spared to make the journey.

An article in the *New Albany Medical Herald*, on this subject, bears out his theory of the pine regions for consumptives, and induced the writing of this communication in the hope somebody might be benefited. In the article alluded to, Dr. David P. Jackson, of Toledo, mentions the case of a young woman, aged twenty, afflicted with asthma, bronchitis, etc., who was sent to Pine Bluff, N. C. In two months she had gained fourteen pounds, could take long walks, and was otherwise greatly improved. She was given no particular treatment, the benefit being all due to the climate, the peculiar conditions of which enables invalids to enjoy outdoor life all winter. The country is made up of white sand to a depth of fifty to ninety feet; there is a good rainfall, and the objectionable features of a rainless region are avoided, but the sand formation gives the dry air and soil needed for the cure of lung diseases.

It is the turpentine region. Pine Bluff is "a winter camp in the pine woods, and the vast forests of the long-leaf pine give terebinthinate and ozone qualities to the air. The water seems to have antilithemic qualities."

Thus it will be seen that this section has a combination of climatic conditions not usually found together, namely, a temperate climate, both winter and summer, a good rainfall, a dry air and soil, and a pine forest *producing ozone*. Access to the place is easy and inexpensive, fuel is cheap and abundant, the expense of living is low, and people of moderate means may avail themselves of the advantages of an economical health resort. Life there is simple, restful and pleasant, the conditions of life being not unlike an old-fashioned Northern country village, with the important exception that invalids may enjoy outdoor life all winter. The place is well adapted to patients from the North, with such diseases as incipient consumption, asthma, chronic bronchitis, catarrhs of the air passages and digestive system, lithemia, Bright's disease, etc.

On the Pocono Mountains of Pennsylvania, where the best results have been obtained in the treatment of consumptives, the hemlock and rhododendron grow. The camp of tents was in a hemlock grove. It seems to me that it is more the peculiar climate favoring the endurance of the pine over other timbers, rather than a fragrance of medicinal virtue eliminated from the tree, which favors the cure of consumption in these special regions over others.

Lactation.

BY D. A. ZWIGTMAN, M. D.,
Niles, Mich.

A few years ago the infant of a primipara died, and the mother having a superabundance of milk secretion, suffered excruciating pains.

I decided to paint the mammæ with a five per cent cocaine solution. The pains disappeared, and with it after two days, the secretion of milk.

I have tried this simple remedy in a number of cases with the same good result, and thought it worthy of communication.

In case there is secretion of milk in the breasts of infants the most simple remedy to normalize the glands is to use belladonna salve on soft, thin leather. In less than no time a cure is completed.

Does Syphilis Secure Immunity?

BY J. HURLEY SCHALL, M. D.,
Consulting Genito-Urinary Surgeon to Jamaica Hospital.
Brooklyn, N. Y.

Mr. J. D., aged twenty-five years, single, was referred to me with the following history:

In January, 1899, he contracted a suspicious-looking sore of the glans penis, which developed about five weeks after having intercourse with a prostitute.

At the time the first lesion appeared, he was in the army, and consulted a Government surgeon of unquestionable skill, who diagnosed a chancre.

The characteristic symptoms of syphilis, in due time, followed.

Under careful treatment the case progressed satisfactorily, all symptoms of the disease clearing up in fifteen months.

Since then he has been under constant surveillance. By close questioning, I was unable to elicit any symptoms that showed he was not cured. April 13, 1902, about thirty-five days after exposure, a second sore appeared, a little below the site of the original chancre.

Upon examination, the erosion presented an oval appearance, with a slight serous exudate. Pinching it between the thumb and finger it gave some resistance, but no pain. There was no edema about its edges.

Bilateral inguinal and epitrochlear adenopathy was marked. Shortly after the appearance of the enlarged glands, the patient complained bitterly of headache, backache and general malaise, with some temperature.

A coppery, brown, macular eruption, appeared on the trunk and loins. It was level with the skin and disappeared under pressure.

The pain in the bones of the extremities was marked.

The lateral portion of the tongue and buccal cavity contained mucous patches, the size of a pea.

The tonsils were hypertrophied, and the pharynx much congested.

These symptoms did not respond to treatment until mercury was given.

The patient did well under specific treatment, all of his symptoms having entirely disappeared.

In the presence of such evidence of syphilis, it seems impossible to diagnose this case as anything else.

141 St. Marks Avenue.

Ottomar Rosenbach — Character Traits of His Life, Collected from Tributes Paid to His Memory.

BY DR. A. ROSE.
New York.

Nothing is more instructive and useful for medical life and work than to obtain an insight into the character of great and noble men of our profession, as it stimulates reflection, and has an ennobling influence upon our education. The idea readily suggests itself to relate a few beautiful features of the life of a man like Rosenbach, not only because he was one of the best and most prominent physicians of his time, but also because he was a special friend of THE MEDICAL BRIEF.

I have published his biography in the April number of this journal of 1904, and paid a tribute to his name in the May number of 1907, while in the present article I propose to present a selection of what those who knew him best, his nearest friends and pupils, have written about him.

The excellent character of this distinguished man, the tender care he evinced for those with whom he came in contact was even demonstrated beyond the grave. He died on March 20th of the present year, and it was only two days later that his friends were notified of his demise; such had been his distinct instructions. Not only had he forbidden any funeral procession, but even every external sign of mourning, so that the ladies of his household were dressed in white when receiving the visits of sympathizing friends who called to condole with them in their bereavement.

His medical activity covering a long flight of years had served to deepen his gentleness of character and the intensity

of his compassion. For everybody he met he showed kindness and sympathy; in the treatment of his patients he displayed that great art of making sufferers feel that he felt with them, while in the examination of the cases he exhibited much gentle care which went a long way to relieve their sufferings.

In every respect Rosenbach was an unusual personality, a physician the like of whom has only rarely existed. His diagnoses were remarkably clear-sighted; in the prognoses he but rarely erred, and in the domain of therapy he was remarkably successful. It is a characteristic fact that a large number of colleagues consulted him for his advice. His love and capacity for work were truly astonishing. An original thinker of rare perception, he was no slavish follower of authorities, but claimed the right of working out his problems for himself, and there were few of these, indeed, to which his reasoning failed to impart a new aspect. Endowed as he was with great power of penetration, gifted with rare kindness of heart and gentleness of disposition, he did many acts of benevolence, always taking care that they did not come to the knowledge of third persons. He had a full understanding for human foibles. His sense of justice was so strongly developed that he invariably came to the aid of those ill-used.

His theoretical conviction could not be shaken, even in the face of the opposition of the majority of his colleagues. Among old practitioners there were many whose views had advanced far enough to follow Rosenbach's flight of thoughts, and to share his opinions, while among the younger generation many colleagues showed more interest and understanding for Rosenbach's teachings than is generally shown by the authorities now ruling. During his comparatively short career his prolific master mind created or remodeled a large number of new and important conceptions, opposed other and older views, attacked long established doctrines, trusting his own soundness of judgment, although it might often be in opposition to the trend of prevailing opinions; in fact, he displayed so far-reaching an activity that his footsteps on the onward march of medical science will forever be indelible.

Among his two hundred and seventy-eight books, monographs, treatises and papers, not one bears the stamp of commonplace or suffers from that narrowness that sometimes marks the repetition of research. In spite of the plentitude of his writings, Rosenbach always presented something new and independent. He was always ingenious, frequently polemic and contradicting; often full of sarcastic humor and pointed irony, but always ready with zealous earnestness to defend against the whole world facts the truth of which he had once recognized. Regardless of his own disadvantage, his mind was forcefully concentrated upon the great truth for which he fought. In this he did not confine himself to medical science, but also included social problems, professional good-fellowship, even questions of natural science and psychology.

Rosenbach had an inclination to occupy his mind with theoretical problems, and this scientific tendency has borne fruit in practical medicine; to it we owe his doctrine of functional pathology, of organic insufficiencies, of the effects of suggestion, of psychic treatment, doctrines for which he had, at times, to overcome much opposition, although at the present time they have long been accepted as established truths. His doctrine of energetics which is not yet sufficiently valued, already finds its practical confirmation in biochemistry and biophysics.

A pupil of his uncle, Traube, and of Cohnheim, he is also responsible for a large amount of exact clinical and experimental work, which has proved of importance. As illustrative examples, mention may here be made of his experiments on the insufficiency of the aortic valves, his doctrine of the mechanism of the vocal cords, the treatment of dilatation of the stomach. He was one of the first to recognize the importance of functional insufficiency in regard to the mechanism of the stomach, and the first mature result of these reflections was embodied in his frequently cited treatise on the mechanism and diagnosis of stomach insufficiency in 1878. By virtue of his writing thus early on this subject, Rosenbach

must be regarded as the founder of functional diagnostics of diseases of the stomach. Since that time the domain of "motor and mechanical insufficiency" has been introduced as one of fundamental importance into the diagnostics of affections of the stomach. It was just this interpretation of the functional efficiency and insufficiency which formed the starting point for Rosenbach's later studies of energetics which he applied to the entire human pathology. To me personally his experiments with carbonic acid were of particular importance, he having demonstrated facts which led me to introduce my treatment of dysentery and rectal fistula. After I had demonstrated and proved that rectal fistula may be promptly, completely and permanently cured without operation by the application of carbonic acid, he congratulated me on having solved this problem.

His activity practically embraced all special branches of medical science; he benefited and developed them all, but none more than the affections of the heart which, by his doctrine of functional diagnostics, were placed on a partly new foundation, his teachings exercising a material influence on prognosis and therapy. By his work on "Diseases of the Heart and Their Treatment," he has acted as pioneer in this respect.

Rosenbach was a born experimenter, and his experiments succeeded in defining the involved problems with rare perspicacity, taking all possibilities into consideration. He recognized the great difficulties which beset the path of a satisfactory experimental answer to a scientific question. This refers especially to animal experiments, in regard to which he warned against exaggerated expectations. He was particularly happy in the critical and successful utilization of his experiments and experiences, his ability of associating ideas being truly wonderful. Thus, on the basis of a case which he had carefully observed himself, together with the critical utilization of similar cases described in the literature, he established the famous law of the different vulnerability of the recurrent fibers. He immediately recognized that this was only a special application of a general law, namely: that in affections of the nerve trunks or of the central organs the flexors are paralyzed later than the extensors.

Rosenbach always considered it one of his principal tasks to support the unification of the medical practice as opposed to the ever-increasing division into special branches, thus favoring the idea of allotting to the general practitioner the entire domain of medicine.

Although he attached great value to experimental research, and readily recognized the importance of their results in the interest of science, he again and again raised a warning voice against the danger of over-estimating diagnostics and therapy born exclusively in the laboratory. In the fight against the ruling power of bacteriology he has likewise achieved success by calling attention at an early date to the protective power of the organism and the multiformity of its reactions, criticising severely the exaggeration of specific treatment.

In 1890, when Koch recommended his tuberculine, Rosenbach's fight against bacteriology had its beginning. In many respects results have already now proved him to have been right; in other points the future will probably prove him to have been right again. His collected papers on this subject were published in his book, "Physician vs. Bacteriologist," in 1903, which produced an effect like a thunderbolt from a clear sky. On the other hand, Rosenbach was by no means an enemy of bacteriology, the importance of which as a biological science he fully appreciated. But he opposed the presumption of the "nothing-but-bacteriologist" theory to consider themselves better judges than the physician at the bedside; he also deprecated the exaggerated fear of infection and the rigorous measures taken for isolation and disinfection as constituting deteriorizing factors in both social and ethical aspects.

Unfortunately, Rosenbach has not met from different reasons with that appreciation which he unquestionably deserved. The principal reason seems to be that he lived too early, at a period where the trend of the times was opposed to the aspirations of "natural philosophy." But

neither ignoring his works nor the disparaging criticisms which sometimes appeared under the guise of scientific dissertations, were able to deprive him of his convictions or of his faith in the final victory of his ideas. For intelligent criticism, however, he was always grateful; indeed, he was better pleased with well-meant censure than with empty phrases of praise.

May the time soon come when the merits of this remarkable man will be openly recognized.

[Written for the MEDICAL BRIEF.]

Fascia of the Pelvic Floor—Perineal Fascia.

BY BYRON ROBINSON, B. S., M. D.,
Chicago, Ill.

The fascia of the pelvis is of maximum value in resisting intra-abdominal pressure at the pelvic outlet. Fascia supports muscles functionate by contracting and relaxing. The levator ani fascia proximal and distal is of the most supreme importance in resisting the intra-abdominal pressure. The pelvic fascia is of marked importance in sustaining and controlling the vagina, bladder and rectum. The visceral fasciæ are exceedingly important in the viscera of the pelvis, as they are merely divisions or blades of the levator ani fascia proximal. The fascia of the pelvis strengthens the pelvic floor, fixes pelvic structures in definite relations, supports in ordered planes nerves, blood and lymph vessels. It prevents splanchnoptosia of the pelvic organs by being coalesced with the transversalis and iliac fascia. A remarkable characteristic of the pelvic muscles (levator ani, transversus perinei, constrictor vaginæ, coccygeus, bulbo-cavernosus) is extensive fascial attachments of one or both ends. The remarkable characteristic of the great levator ani muscle, is it is reinforced, backed, by powerful fibrous planes of fascia proximal and distal.

Fascial Nomenclature.—Onamatology becomes more important with the progress of medical science, owing to its increasing complexity.

As a teacher of anatomy I maintain that a fascia should be named according to the muscle or other structure with which it is in the most intimate relation. I shall, therefore, apply this simple nomenclature to the fascia of the pelvic floor.

The fascia covering the obturator internus muscle will be termed the obturator fascia. As this fascia is divided by the "white line" arcus tendinous extending from the dorsal surface of the pubis to the ischial spine, we will call that portion of the fascia proximal to the white line the obturator fascia proximal, and that portion of the fascia distal to the white line the obturator form distal. The fascia proximal to the levator ani, originally named by Tyrrell the recto-vesicle, and by Carcassone the pelvic aponeurosis, by others the vesical layer of the pelvic fascia, we will name the levator ani fascia proximal, and that part of the fascia distal to the levator ani, the levator ani fascia distal. The fascia covering the coccygeal and pyriformis muscles will be named according to those muscles.

The fascia covering the sacrum very naturally takes the name of the sacral fascia. With this substitution of simplified terms for the previous complex and multiple nomenclature in the pelvic fascia, we will proceed with a detailed discussion of the subject. The following table presents a comprehensive view of the pelvic floor fascia and the simple, natural nomenclature which I have adopted:

(C) Fascia of the pelvic floor.	1, Levator ani fascia, proximal and distal.	
	2, Obturator fascia, proximal and distal.	
	3, Coccygeus fascia, proximal and distal.	
	4, Pyriformis fascia, proximal and distal.	
	5, Sacral fascia.	
	6, White line (arcus tendinous).	
	7, Perineal fascia,	(a) superficial fascia, superficial layer.
		(b) superficial fascia, deep layer.
	8, Trigonum urogenitale—triangular ligament.	

THE INTERNAL PELVIC FASCIA.

The fascia of the lesser pelvis has a poor literature, and is not often described. As the pelvic floor fascia has much to do with the permanent results

of the flap or any perineal operation, I will write of it somewhat in detail.

The fascia of the greater pelvis, or that fascia lying proximal to the ileopectineal line, is not here considered. The fascia, the planes of strong fibrous tissue here under consideration, lie distal to the ileopectineal line.

The internal fascia of the lesser pelvis extends from the ileopectineal line on either side to the median raphe of the pelvic floor. It not only lines the pelvic walls and floor, but enters into intimate relations with the pelvic viscera. It is a strong, shiny, fibrous membrane, possessing a very varying quantity and quality. In a certain sense the fascia of the lesser pelvis should be treated as an independent structure, and not as a continuation of the iliac transversalis or other fascia. The ileopectineal line marks an absolute division between the iliac and obturator fascia.

The simplest plan is to describe the obturator fascia proximal (superior) and distal (inferior) and to consider the obturator fascia as distinctly belonging to the obturator (internus) muscle, subsequently to consider the fascia of the levator ani proximal (superior) and distal (inferior) with a lesser consideration of the coccygeus, pyriformis and sacral fasciæ. The fasciæ lining the lesser pelvis are intimately connected with their respective associated muscles and structures by strong connective tissue. The connection of the fascia with the peritoneum is not intimate, as thick, spongy, loose layer of the connective tissue, richly laden with fat lobules, lies between the peritoneum and the fasciæ lining the lesser pelvis. This loose connection of pelvic peritoneum and pelvic fascia allows the easy and rapid spread of pelvic abscesses between the pelvic fascia and the peritoneum in the subperitoneal tissue.

The obturator internus fascia surrounds the obturator muscle at its origin, from the lateral pelvic surface of the innominate bone, and is the special fascia of the obturator internus muscle. It is attached for a considerable distance to the iliac portions of the brim. At this point the obturator becomes attached to the proximal border of the obturator membrane. Ventral, the attached line of the fascia, passes distal, the ileopectineal line, to allow the obturator vessels and the nerve to enter the obturator foramen or canal. This portion is fixed to the periosteum and appears as an independent organ. Ventrally it is attached to the body of the pubis and along the proximal margin of the obturator foramen by an oblique line, to a point about one-half an inch distal to the symphysis. Where the fascia dips distalward to allow the passage of the obturator vessels and nerves it is firmly attached to the periosteum and nerves by strong tendinous fibers. Dorsally it is attached to the ventral surface of the great sacrosciatic ligament and the ventral margin of the great sacrosciatic notch. Distalward the fascia is attached to the margin of the obturator foramen of the descending ramus of the pubis, and it joins the falciform process of the great sacrosciatic ligament which firmly connects it to the internal border of the ischium and its ascending ramus.

With a firm insertion in the ileopectineal line, the ventral border of the great sacrosciatic foramen, the ventral and distal margin of the obturator foramen and to the edge of the falciform process of the great sacrosciatic ligament, the obturator fascia becomes a fixed, strong, thick, fibrous membrane in relation proximal ward with the obturator nerve and vessels and distalward with the internal pudic vessels and nerves, Alcock's canal. It has intimate attachments to the obturator internus muscle proximalward, but is quite loose distally.

The obturator fascia we divide into two portions proximal (superior) and distal (inferior). The obturator fascia proximal is that portion proximal to the white line or arcus tendinous. It presents into the pelvic cavity from the lateral aspect and is covered by peritoneum. The peritoneum and obturator fascia proximal are separated by considerable loose, fatless, snow-white connective tissue, composed of many shiny, thin, cleavable planes, which become easily dissected by the progress of pelvic abscesses.

The structures of importance which pass over the internal face of the obturator fascia proximal, distal, the ileopectineal line, are the obturator vessels and

nerves. These structures are liable to be injured by the head soon after its engagement by the brim or fixed bony ring of the pelvis. The obturator fascia proximal has a surface of about ten square inches.

The obturator fascia distal is that portion distal to the arcus tendinous, or white line. It presents internally into the ischiorectal fossa and externally toward the obturator internus muscle. It forms the external boundary of the ischiorectal fossa. At the distal part of the ischiorectal fossa, about an inch proximal to the tuberosity of the ischium, the obturator fascia planes become separated, producing a sheath—Alcock's canal—for the transmission of the pubic vessels and nerves. The obturator fascia distal has a surface of some five square inches, one-half the size of the obturator fascia proximal.

At the lesser sciatic notch the obturator fascia make its exit from the pelvis with the muscles and gains the dorsal femoral regions of the thigh. The obturator fascia is inserted into the ramus of the ischium and pubis, where it continues and blends with the triangular ligament of the urethra; hence the triangular ligament is a continuation of the bilateral obturator fascia.

The arcus tendinous, or white line, appears as an aggregation of tendinous fibers of the obturator fascia. It extends from the surface of the pubis to the spine of the ischium. It possesses a gentle curve or extensive radius with its concavity proximalward. The white line originates to that part of the levator ani muscle which arises between the distal dorsal surface of the pubis and ischial spine. The white line arises from the ligaments of the bladder; a thickened portion of the obturator fascia is the line or origin of two planes of fascia. The proximal plane I call the levator ani fascia proximal. The white line varies in thickness in individuals—generally is one-sixth of an inch in thickness in the middle, but its greatest strength and width is at the ventral end, where it assumes intimate relations with the pubovesical ligaments. In woman the white line is about four inches in length. Its origin at the pubis may be chiefly from the ventral lateral (true) ligaments of the bladder. The white line possesses considerable elasticity. It is quite firmly fixed at the ventral end, but, like a long, tight rope extending from two distant points, allows considerable range of motion and sagging in the middle.

The levator ani fascia proximal (rectovesical fascia of Tyrell, rectovesical aponeurosis of Carcassone or visceral layer of the pevic fascia) arises from the white line and passing medianwards aids to form the floor of the pelvis. The levator ani fascia proximal, as its name implies, covers the proximal surface of the levator ani muscle. The fascia loses itself in the median raphe dorsal to the rectum in the rectal, vaginal and vesical walls, and in the ventral and lateral ligaments of the bladder. From this relation, the levator ani fascia proximal becomes of significant interest in perineorrhaphy. Ventrally it is remarkably strong and short, being attached to the dorsum of the pubisproximal to the obturator fascia, from which it is separated by the origin of the levator ani muscle; the levator ani fascia proximal to the levator ani muscle and the obturator fascia being all three intimately adherent to the pubic bone and to each other.

If one carefully removes the peritoneum and loose subperitoneal tissue the levator ani fascia proximal may be plainly seen stretching, extending from the white line to the bladder, vagina and rectum. It may be stripped from the levator ani muscle in several thin, cleavable planes. It is reflected on the bladder forming the ventral (true) and lateral (true) ligament of the bladder; however, the lateral ligaments of the bladder may be assisted by ligaments from the vagina. The levator ani fascia proximal begins its ventral attachments at the distal border of the symphysis, continues then along the white line laterally to the ischial spine, continues from the ischial spine on the proximal surface of the levator ani muscle to the median raphe. The levator ani fascia proximal covers an area of about six square inches on each side of the median line of the pelvis.

The levator ani fascia proximal may be divided into the ventral or vesical portion, the vaginal and rectal portions.

The vesical portions of the levator ani fascia proximal is reflected from the pubis to the neck of the bladder, forming the ventral (anterior) true ligaments of the bladder and part of the lateral ligaments. The vesical portion is very thick and strong, even tendinous. It is reflected from the pubis in an arched manner. The vaginal portion of the levator ani fascia proximal is analogous to that which surrounds the prostate in the male. In the male, the prostate gland and vesiculæ seminales are surrounded by a strong capsule derived from levator ani fascia proximal. This portion of fascia surrounds the vagina in the female, including the large venous plexuses.

(To be continued.)

Influenza's Contemporaries.

BY JOSEPH D. HARRIGAN, M. D.,
New York.

Thousands of observers have written upon the subject of influenza, that inexhaustible field for conjecture, and yet, if no change of direction of the mental activities eventuates, the list might continue to many thousands more, with the mysteries surrounding the dread visitor's approach, still unsolved.

Although the remarkable phenomena that have, from time to time, accompanied the various visitations of influenza, been faithfully recorded, and a connection between them been duly acknowledged to exist, one great oversight seems to the writer to have been committed by various observers.

It has consisted in this, viz.: The attempt to ascribe to *the phenomena themselves* some connection, whereas the *cause* of these phenomena should have been the proper matter to have come in for thorough investigation.

In other words, it is that which is *back* of such phenomena as the blood-rains, the blood-dews, the brick-rains, the fire-rains, the ill-smelling fogs, etc., which must furnish us with the clues to the cause of influenza, and the whole family of plagues.

The relationship of influenza to these phenomena of history is about as interesting a study as one could possibly occupy one's self with.

Professor Theophilus Thompson wrote, in 1852:

"We are indebted to Ehrenberg for some remarkable illustrations of certain phenomena, once supposed to rest only on the evidence of superstitious fancy, but proved by him to have existence, and to be associated with atmospheric changes. In his work 'On the Dust of the Regular Winds,' he has made it evident that a phenomenon, occasionally noticed in these annals (Annals of Influenza), has been, from time to time, recorded under the names of dust-rain, blood-rain, blood-dew, flesh-rain, brick-rain, ink-rain, fire-rain, cosmical dust, dry fog, fog coast of Western Africa, and Atlantic dark sea, or sea of darkness, etc. Ehrenberg has shown, by microscopical analysis, that in addition to various mineral materials, such as silica, alumina, oxides of iron, manganese and copper, this dust contains various polyastrica, polythalamia and phytolitharia."

Now, instead of losing one's time over the impossible task of trying to adapt any one or more of these materials as the cause of influenza, it would seem more reasonable to investigate the causes of these phenomena, with the expectation of possibly lighting upon the actual, bona-fide common cause, if, even perhaps, it might be by accident.

In other words, inasmuch as influenza is so frequently an accompaniment of these phenomena, it is perfectly logical to infer that in discovering the prime cause of these various rains and fogs mentioned, the discovery of the cause of influenza must inevitably follow, or, at least, the road to it must be clearly indicated.

The principal and most absorbing question that should have been discussed, and the problem to have been worked out was: Whence came these extraneous materials into our atmosphere, and of what are they composed?

The excellent researches of Ehrenberg have shown the composition of the inorganic chemicals, making up the dust-rains, etc., and we know that the blood-rains, etc., are really of blood enclosed in

most delicate membranes, constituting organic, living creatures, but still more interesting and important would be a knowledge of the chemical constitution of these organisms.

Still more interesting even than the study of the composition of the various materials that can be regarded as extraneous adjuncts to our atmosphere, is the working out of the problem of the origin of these materials.

Whence do they come? Are they merely earth-born, wafted on the winds to the higher strata of atmosphere, and, driven hither and thither, finally finding a resting place once more upon that same earth from whence they sprung?

Or are they foreign visitors from some near or distant planet, driven by some mysterious force into exile in space, only to be attracted by the gigantic power of the earth's magnetism, and compelled to pay us a visit, in a manner exactly similar to the visitations of meteors, etc.?

Or is it reasonable to consider for a moment the possibility of their spontaneous formation in the higher regions of the atmosphere, exactly as the particles of ice making up the scirrhi are formed?

Finally, as the one remaining possibility, seemingly, are their formations due to the union of elements possibly present in the ether of space, with the elements that go to make up the atmosphere of the earth that is extended for many miles into that ether?

The last possibility is the only one that appeals to the writer as adequately sufficient to explain the many phases of the whole question to one's complete satisfaction.

"Nature's Laboratory" does not remain confined simply to the earth; nor is there, in reality, any boundary lines to it within the ken of man. Neither is the ether a great void space, as the visits of meteors to us clearly prove.

On the contrary, all the great facts in astronomical history give unmistakable evidence that space is crowded with effete products of combustion, both in gaseous and solid form—with all their inherent tendencies to collect in masses by virtue of not only their intrinsic attractive forces, but also by the chemical natures with which they are endowed. And, furthermore, by virtue of these characteristics, both chemical—and, as a matter of course, electro-chemical—there is absolutely nothing lacking for the formation of innumerable varieties of entirely new chemical combinations, either non-organic or organic.

In this connection it might be well to recall the experiment of Mr. Crosse of Broomfield, England, as mentioned in Beard and Rockwell's Medical and Surgical Electricity, pp. 47, 48, of which the writer has spoken in previous articles.

Quoting from the work mentioned we find that:

"Electro-chemical action continued for weeks, months and years, as was done by that very laborious experimenter, Mr. Crosse, may produce as secondary results interesting minerals, such as quartz, aragonite, malachite. During these experiments in electro-crystallization, Mr. Crosse discovered that remarkable insect, the acarus, which appeared in electrized solutions of sulphate of iron, sulphate of zinc, and nitrate and sulphate of copper. * * * Mr. Weekes, of Sandwich in Kent, subsequently repeated the experiments of Crosse by passing electrical currents through silicate of potash in glass receivers over mercury. All possible care was taken to keep out foreign matter. After a constant action of a year insects appeared, entirely similar to those obtained by Mr. Crosse."

Comparing this experiment, carried out on an infinitessimally small scale comparatively, with the vastly more extensive operations carried on for ages in Nature's laboratory, should not the results be exactly similar, only with infinitely greater results?

And these operations are going on continually, not only in the depths of the earth, but also in the atmosphere that extends for many miles towards space.

We well know that this atmosphere is surcharged with electricity. We know also that, basing our knowledge upon Ehrenberg's discoveries, this atmosphere is laden, at times, with all the materials that make possible the creation of both inorganic and organic matter.

There are present similar chemicals, exactly as in the experiments above-mentioned, as likewise the electricity necessary for proper fusion, if one might call it so, prepared by the Creator, simply awaiting His word for the consummation of His wishes, the ultimate result consisting of the formation of organic or inorganic matter, altogether dependent upon the Creator's bestowal of or withholding of that inestimable gift called life.

The conclusion must force itself upon us that wherever the proper chemicals are present, and the proper welding force, if one might term the electricity that goes to make up an indispensable part of the operation, there can be, in the nature of things, but one result, a chemical combination, either inorganic or organic.

It is but a step from inorganic to organic being, just as *vice versa* it is but a step from life to death, and the experiments carried on in the laboratory by Mr. Crosse and Mr. Weekes, conducted under conditions insuring the utmost accuracy scientifically obtainable, prove beyond the question of a doubt that it is merely a matter of chemicals and electro-chemical action, by means of which, with the permission of the Creator of all things, these various transformations are brought about.

It will be recalled that in Mr. Crosse's experiments, it was whilst he was developing inorganic minerals, such as quartz, arragonite, malachite, etc., he accidentally discovered the organic chemicals called acari.

This would seem to indicate that in all such electro-crystallizations, both organic and inorganic chemical transformations go hand in hand.

In other words synthetical chemistry is not by any manner of means confined to the inorganic chemical world, but embraces in its scope the organic world besides.

The Great Omniscient simply utilized the chemical laws which He Himself had instituted, and after creating the earth, made man out of its slime (in a word, its chemicals), to enjoy it.

Now, it is not surprising to find that Professor Ehrenberg, in his researches above-mentioned, discovered organic as well as inorganic constituents of the dust and air.

There is ample justification for the theory that these organic constituents sprang into existence contemporaneously with the inorganic formations.

Numerous and intricate operations productive of innumerable effects must certainly be expected to be constantly transpiring in the atmosphere, as well as in the earth, and of these, organized materials, must, almost of necessity, be a part.

Now, it is a fact that the organic materials in the Crosse and Weekes' experiments developed from electrized solutions of sulphate of iron, sulphate of zinc, nitrate and sulphate of copper, as likewise, silicate of potash.

But, according to Professor Witthaus, as likewise Professor Ehrenberg, as already mentioned, and many other scientists, the air is laden with most diverse varieties of chemicals, among them the chemicals of the Crosse-Weekes' experiments. We are also aware of the presence of electricity, in greater or less quantity.

At different times this latter constituent is in far greater abundance than usual.

Now, if, for the sake of argument, it were admitted that these organic and inorganic materials found in the atmosphere sprang into existence from the union of various chemicals present therein, we would expect to find the process almost constantly transpiring, provided, of course, the chemicals were earth-born.

But history tells us that they are periodic in their visitations, consequently we must seek in space for the chemical ingredients that go to make up the complement, the earth doing its share towards the destined end.

Just as we have periodic visitations of meteors, and their spontaneous combustion in our atmosphere as they approach the earth, we must expect to have visitations of the gaseous chemical materials, coming to us through space from similar points or foci of combustion from which the meteors had their origin.

And similarly to these meteors, a chemical combination is formed with the

chemicals of our atmosphere, the result being extremely variable, increased amounts of electricity as one effect, formation of inorganic chemical combinations a second, and last, and most important of all, the formation of organic matter.

Just as the meteor, in its passage through our atmosphere, develops spontaneous combustion, so the various gases, products of the great conflagrations that have raged in past ages in space and still continue to rage, and which must be encountered by the earth, perform their part, an extremely varied one—so-called spontaneous development of life being the principal and most important.

One seems to be as much justified in considering that the great edict of the Creator's: "Let there be light," held good merely for some remote period of time, ages and ages ago, as the still greater command of "Let there be life."

We see fresh life springing up all around us, every day and every hour, and it certainly seems reasonable to expect to find (so-called) spontaneous generation eventuating wherever and whenever the materials necessary for its production are present.

Thus it is easy to see how, with the lightning flash (an example of spontaneous combustion), not alone are inorganic chemicals, such as nitric and nitrous acids in combination with ammonium produced, as likewise many other chemicals, but even organic chemicals are also produced.

We poor mortals are accustomed to speak of the creation as having happened in some remote time, ages ago, and as having been, ages ago, completed.

We forget that, with the Creator, it is one eternal day—always the everlasting present.

The creation was begun in what, to us, is past time, but it is also continuing in the present, and extends from the highest forms of life down to the lowest.

What might seem a miracle of the laboratory, in the Crosse-Weekes' experiments, is as nothing to the overwhelming miracles constantly permitted by the Creator to be witnessed by us at all times in Nature, new beings springing into existence always and ever.

Now, one might inquire, what connection, providing this is all true, exists between these organic and inorganic materials and influenza?

Simply this:

They serve to indicate the presence in the earth's atmosphere of chemicals inimical to higher forms of life, but extremely favorable to the development of the lowest forms.

There is an in-balance of the chemical and electro-chemical adjustment of the atmosphere altogether in favor of lowest life development, and *per contra*, productive of disturbed nutrition in the higher forms, hence epidemic disease—exactly like the in-balance of chemicals in the food supply that disturbs the nutrition of the tissues, and produces the disease known as scurvy.

Hence it is not the material products of this in-balance that are, in themselves, to be feared—althqugh, secondarily, they may, no doubt, cause trouble enough—it is the in-balance itself that works the mischief.

Where the lowest forms of life find easiest development, there higher forms can not thrive.

Rather than place the blame for disease engendered, for example: in the damp atmosphere of a cellar, upon the low forms of life developed in that cellar —whether those forms of life are worms or germs, it would seem far more logical to seek the cause in the chemical and electro-chemical in-balance that certainly prevails there, and that must be reckoned with, as justifiably as is the reckoning of the in-balance of the chemicals of our food.

An in-balance of the food chemicals produces disease, *e. g.*, scurvy, as noted. Where many are attacked at or about the same time it means an endemic or epidemic, as the case may be.

Similarly, an in-balance of the air chemicals also produces disease, which is usually endemic or epidemic.

Thus it is with influenza.

Clearly and unmistakably caused by the same in-balance of the earth's atmospheric chemicals, it is not at all surprising to find it accompanied, at times, by such formations of lowest organic materials

as make up the blood-rains, blood-dews, moulds, etc., spoken of in history.

There appears to be but one logical conclusion to be deduced with regard to these contemporary phenomena to influenza, viz.: That they are but companion effects.

A common cause for both exists and is to be found in the in-balance of the air chemicals.

Taking into consideration the periodicity of these phenomena as well, also, their unversality, we must seek in the earth movements through space for a cause.

Inasmuch as the earth must, in its career, run into huge volumes of gaseous chemicals, products of the great conflagrations of space, just as it runs, at times, into the more solid products, as evidenced by our meteoric displays, it seems logically certain that we must look to these gaseous chemicals as the causative factor in the chemical and electro-chemical in-balance that without a particle of doubt prevails.

All nature participates in this in-balance.

Witness the furious storms as recorded in history.

Note the great (natural) famines.

Observe the great increase in the lowest forms of life at the expense of the highest forms.

This development of lowest forms of life is not confined or restricted to any particular place or station.

It goes on in the air, on the earth, or in the waters of the earth. In the animal or in the plant—there also does this in-balance cause new development of lowest life. Wherever the chemicals can penetrate that, with the aid of their inherent electro-chemical action, produce this in-balance, there will new forms of life—call them germs or what you will—eventuate.

Thus, the germs found present in the body in influenza can no more be regarded as the cause of the disease than the blood of the blood-rains, or the strange moulds that have, at times, prevailed contemporaneously with the disease.

They are simply products of an in-balance in nature favorable to them, but wofully unfavorable to man.

The Bible and Morality.

BY R. C. CAVE,
St. Louis, Mo.

It is said by some that, if men were to lose faith in the Bible as a divinely-inspired revelation of truth and duty, the bulwark of morality would be gone, and society would be in a state of moral anarchy. They seem to think that, unless men regard the moral law as peculiarly divine in its origin, they will feel under no obligation to obey it, and will, forthwith, proceed to break every commandment in the Decalogue. But those who take this view of the matter will hardly admit that *they* would become liars, thieves, and libertines, if they were not restrained by commands given directly from heaven; and, if they can free themselves from the notion that they are made of superior clay, they may be able to see that such commands are not necessary to hold others in the paths of truth, honesty, and good conduct.

The history of mankind clearly shows that man is not dependent on the Bible for either the knowledge or the practice of morality. He is not indebted to any divinely-inspired book for his ideas of right and wrong. He gradually gathered knowledge of what is right and what is wrong from experience, and the knowledge thus gathered was written down in books which afterwards came to be regarded as divine. As far as it relates to morality, the Divine Book merely inculcates that conduct already shown by experience to be wise and good. And we find that men who knew nothing of our Bible gave precepts for the regulation of conduct which compare most favorably with the best teaching of Hebrew prophets and Christian apostles. Confucius taught, in other words, the golden rule, which Jesus declared to be "the law and the prophets." Those who have searched the records of ancient Egypt, tell us that, in the rules regulating the social life of that people, "none of the Christian virtues is forgotten." It has been said, and is probably true, that Moses, in giving the Decalogue, merely formulated principles learned from the Egyptians; and

every moral duty enjoined by the Decalogue is enjoined with equal clearness and force by the Buddhist scriptures. Pages of the BRIEF might be filled with quotations from the literature of people who never heard of our Bible, but who, nevertheless, had moral precepts of the highest order. Such quotations clearly show that man is not dependent on our Bible for moral instruction.

And history shows that faith in the Bible as a divinely-inspired revelation of truth and duty does not make men more moral in conduct. Other things being equal, those in "heathen darkness" have been no more immoral than those who have had the light of the Bible to guide them, and the authority of the Bible to restrain them from evil and impel them to good. If we may believe what their prophets say of them, the Jews, "unto whom were committed the oracles of God," were no better than their neighbors. Ezekiel mentions, among the sins of Jerusalem, the lack of respect and reverence for parents, the oppression of strangers, the "vexing" of widows and orphans, extortion, bribery, incest, and murder. Jeremiah said of his people: "They be all adulterers, an assembly of treacherous men, and they bend their tongues, like their bow, for lies. * * * Every brother will utterly supplant, and every neighbor will walk with slanders." The moral state of those who did not have the "oracles of God" could not possibly have been worse than that thus described. Turning to the history of Christians, we find that they can rightly claim no very great moral superiority over the adherents of other religions. The moral conduct of the disciples of Budda, Confucius, or Mohammed, could hardly ever have been worse than that of even the rulers of the church, in the tenth century, "who," as Mosheim tells us, "indulged themselves in the commission of the most odious crimes, and abandoned themselves to the lawless impulse of the most licentious passions, without reluctance or remorse; who confounded, in short, all differences between just and unjust, to satisfy their impious ambition; and whose spiritual empire was such a diversified scene of iniquity and violence as never was exhibited under any of those temporal tyrants who have been the scourges of mankind." And, since history thus shows that men with the Bible have been just as immoral as men without it, I fail to see how it can be rightly called the bulwark of morality.

And, even if faith in the Bible as a divinely-inspired revelation did make man more moral in conduct, it would not make him more moral in reality. True morality consists not in the conformity of the conduct to a rule of life commanded by some outward authority, but in the conformity of the character to righteousness, so that what is seen to be right will be done, whether an outward authority commands it or not. The man who would steal, if the Bible did not forbid theft, is a thief at heart. He is rotten at the core. And so, in every case, the morality which consists in obedience to the Bible as an authoritative revelation, and would cease to exist if the Bible were not so regarded, is spurious.

Race Suicide.

BY J. A. HOUSER, M. D.,

Author of "Is Marriage a Failure?" "Knocking at the Gates of Hell," "Beautiful Woman," "Zenda," "The Spirit of Life," etc., etc.
Indianapolis, Ind.

Race Suicide.—The human family had its origin, like all else of animal life, in cell structure, and developed upward to its present condition. What this condition is, as compared with the stages of the past, is not hard to decide, but what rank it may take when compared with the future, is a matter of conjecture that each must settle for himself.

The optimist can easily persuade himself that the race will go on to perfection, physically and morally. The spiritually-inclined can see it evolve into a race of immortals with the coming of the millenium, while a pessimist sees the human family on the down-grade toward its primitive state. Each of these views arises from sentiment rather than from a basis of physical facts. Any course, continued unchanged, that a traveler may take, will bring him to the place from which he started. This seems true,

also, of the forces of nature and all they govern. From this view of man we must conclude that he will return in his rounds to his origin.

The very fact of a beginning carries with it the evidence of an ending. That which is endless is without a beginning. To even permit the suggestion to enter the mind that man's sojourn on earth has its limitations, set by infinite forces, is a tragedy oppressive and awful. It takes the thinker to contemplate a voiceless and barren world. As unpleasant as such a conjecture is, it has at least two avenues by which it may come; one, the changing of the race until it will no longer reproduce its kind, and the other, the cooling processes of the earth until the temperature shall preclude all animal and vegetable life. In this case, the human family, with all other forms of life, will wrap the mantle of eternal snows about it and lie down to the slumber of an everlasting winter.

But it is my province to speak of the race as hastening its end by some act of its own rather than by the course of climatic events. The first act of life is to multiply, the next to enjoy, and the last to think, if we are content to divide it into three stages. Either of these carried beyond a certain, though not a well-defined, point, unbalances the conditions that give and maintain an equilibrium, and robs the others of their power.

This compensation is everywhere present in the constitution of matter. It is the way some infinite force has to shape the ends of nature. It may be God's way to retain His throne in the world of matter.

In every living organization, if any part receives more than its share of the vital power, it is at the expense of the rest. The oak tree will serve as an example in the vegetable kingdom. In the cleared field, where the solitary tree is spared by the destroying ax of the woodman, the sun stimulates the lower limbs to a greater growth. Their vigorous life soon drinks up all the sap, the blood and life of the tree. The topmost branches get little and less, become puny and wither, and death draws his line of demarcation just above the healthy bough, and all above that is dead.

In the human forest this analogy holds good. Many a man uses up all his life force in the development of his muscles, and, like the oak, dies at the top first. He is a great, strong animal, but so weak mentally that he has but a child's mind to direct his bodily exertions.

So the brain may be developed until it uses all the vitality belonging, by right, to the other parts of the body, and bring weakness, disease and death. Too great development of the brain and the nerve centers is at the expense of the vital forces, and especially the reproductive powers, and ranks as a cause of race suicide.

An example is found in the excessive development of one part of fruits. The apple, too greatly developed, has but rudimentary seeds, or none at all. So with the pear, strawberry, or any other fruit or vegetable unbalanced by over-development. But the apple, uncared for, goes back to the primitive seedling.

Man, developed mentally beyond a certain point, becomes barren. He is a semi-psychic, mentally-spiritualized being, but lacks the power to transmit his life. He is often exalted, transcendant, but not physically transmittal. He is seldom great, intellectually, but a few examples, scattered through the past, mark epochs in the history of the race. Charles Sumner and Wendell Phillips are illustrious types in our own country. They inherited great mental powers and patiently developed them until their lives were transformed into the spiritualization of humanity. Thoughts carried them above the tempest of the blood. They left the world the best of mind, but no reincarnation of themselves in the person of a child.

It is said that Wendell Phillips' wife sought him in marriage that she might have the honor and glory of bearing a child for the chief champion of human liberty, but she learned, later, that she had wedded a great soul who transmuted his animal life into the beatific glory of the mind, and had none left to transmit to another.

Had Charles Sumner been different in body and less in mind a certain Russian official, accredited to the United States, might not have been returned to St. Petersburg.

Below these illustrious examples of sterility, because of over-development of the mental organization, there are thousands whose chief point of mention is their inability to obey the first command the race received from the Creator. I speak of man, of course, in the generic sense, referring to the males first. But the education of the mental to the exclusion of the physical, shows far more effect upon the women than upon the men. For every sterile man there are six barren women. It is rarely they show any great mental genius, but rather lack of vitality. They are undeveloped as women. A few are masculine in their tastes, and coarse in their natures. But the great majority are refined to the point of unnatural sensibility. Pure, chaste, hysterical, spiritualized, delicate, weakly women; the prey of morbid hallucinations, dreamy, soulful fads. Early in life they are shocked at nature's processes, and are, later, irritated because humans are animals.

These women are undeveloped as women. Their sexual system is infantile. At eighteen or twenty they are children sexually. That influence on life from a healthy, vigorous generative system is absent, and the whole character is out of balance. They frequently form a sentimental attachment for girls, dolls, pictures, and certain books of a weak and sterile sentiment. They are never heroines; they lack the force and courage of gender. Though frequently married, they are never wives. They are wedded disappointments, but less so than their male counterparts.

The life and education of girls invite this cause of race suicide. Some reproduce, occasionally, through long-divided periods. The offspring of such have little to thank their mothers for, nor that little long, as their allotment of life soon runs through the hour-glass which contains it. The husbands of these weakly, undeveloped women are the unfortunates of disappointment and temptation. Though married, they have no wives, except in name, and are thus barred from other society and a more successful marriage. Foiled in the legal union, they seek illegally what they failed to find by law. They are met more than half way by the disappointed wife of another, who has found marriage a failure in providing her a home and support. If he does not find the suitable companionship in the wife of a failure as a husband, it will be in some single woman who ought to be married. She, weaker in mind than in gender, seeks to gain at least some of the pleasures, out of marriage, that every woman should have the opportunity to find in it—companionship and support.

It is very rarely that a manly man transgresses in marital affairs without some serious incompatibility at home. An honorable woman never does so. But when those who expected to find an Eden in marriage waken to the fact that they have gained only the possession of a barren desert, swept by the storms of discontent, it is quite likely that they will be tempted by forbidden fruit. As the starving seek food, the freezing fire, so the empty life seeks to fill the void.

But these mismated marriages swing open the doors of temptation and furnish a thousand causes for hypocrisy.

Love is the honest guide for the girl, the financial recourse for the widow, and the mask for the deceiver.

The storms of passion, unchecked, wreck more than the storms of the sea, and the flat of virility often taints one life to save another.

Birth gives every maiden the jewel of virtue, but her will and conscience must be the key to the casket.

When a girl is born the gods alone can foretell her destiny, but the fates may even fool them.

The love of the heart and the hope of the soul are only too often the slaves of the instincts of nature.

Schools should educate girls in a threefold way, physically, morally, and intellectually, and prepare them to be good wives and mothers.

A great nation must have a great mother.

Girls should attend schools for girls only, that the physiology pertaining to human life may be taught. In a mixed school Dan Cupid is usually master, and what he teaches is often indelicate and unprofitable.

Strong, healthy and sincere wives are the evangels to save the race by saving their husbands. They need not seek missionary work in foreign lands. They can marry and begin at home. God would hardly send a woman thousands of miles away to waste her energies on a helpless yellow Pagan, when a far better or worse man across the street needs her attention.

Prevention.—Limiting the number of offspring by artificial means, I am aware, is a delicate subject to write about, but as it has greatly to do with both the adults and the unborn, and many that should be and are not born, I shall defy the morbid sensibilities of those whose only virtues are found in feigned ignorance and assumed purity.

To discuss something of which everybody knows who has reached the age of puberty and reason, is revealing no painful facts. If anything is evil to the race, or hurtful to a number, the fact justifies the discussion of the subject.

It would be futile to say anything unnatural is harmless, and in this case incalulable harm may come, both physically and morally. But to say that everything that transcends what we usually consider the bounds of natural laws, is sure to bring death, or even harm, would be far from fact. Indeed, it is not an easy matter to say, definitely, where nature stops and art begins, in the conditions of human life. In the strictest sense of the term, there is no purely natural life lived by a human being, or even a domestic animal. Nor would the creature attempting it long survive. The natural man would be naked, live out of doors, and eat uncooked food; for all these things make up life of art protecting nature. So is the barn for the horse and cow, and other domestic animals. In short, life in this climate would not long survive without the aid of art. In a sense, this need not be unnatural or hurtful. So I will differentiate by saying only the hurtful is unnatural.

A person may live the simple life and still have the benefits of art, the house, clothing, cooking, and all else of civilization.

Many means resorted to in limiting the number of children are hurtful, as every physician must know and guard against. But the doctor's opinion is, usually, considered an argument for children, as he may get fifty dollars for an obstetric case.

The sermons on cheating nature are heard with reverence and silence by the laity, but, like most preachments in many directions, forgotten until heard again. Then the minister may have such a small family himself as to lessen the force of his argument. Sometimes the listeners do more thinking than the talker.

With all the talk on this subject, and without spoken opinion against it, the stork is shooed away, and when he obtrudes his presence with his gift, he is not always welcome.

Once, while on a lecture through the West, it was my lot to spend Sunday in a Missouri town. The landlord of the hotel asked me to accompany him to church in the evening. When we entered the church I saw, to my surprise, a congregation of colored people, and a fine specimen of darkest Africa in the pulpit. Seeing my surprise, my friend assured me he had made no mistake in seeking the place of worship.

"That old man," he said, "preaches tonight on President Roosevelt's pet theme, 'Race Suicide.'"

I was interested. During the sermon the sable orator hewed to the line and spared not. He said: "Dar am sumfin wrong wid dis hah church. Here am big, strong married folks, who have been married years, and not a pickanniny in de house. Why, look at yo' ol' hen. Ebery spring she hatches huh brood. Go thou and do likewise!" At this juncture an old colored mammy, noted for her children, that numbered in the 'teens, arose amid a dead calm, and said: "Mistah Johnsing; I wants to say a wo'd. I'se tried de hatchin' and advise against it. Dat ol' hen don' hab to tak' in washin' to get calico for huh yong 'uns."

If Brother Johnson could have insured support for the children, so they would not be a burden to the poor parents, his sermon would have been effective.

The question of children resolves itself into the phrase, "fewer and better." The

strength of the nation is not in numbers, but in kind. The parents who bring more children into the world than they can properly support, educate, and care for, are criminally unwise, if not cruel and barbarous. It is much like confining five sheep where there is pasturage for but two. Two live and three die. While the superfious children, born to parents who could properly support them, do not always die physically, want robs their little, growing bodies and filches from their minds the opportunities for mental life, while privations may lead them to moral death. Were it not for the pinch of poverty and claws of want, many a boy would not have contemplated the mistakes of life behind prison bars, nor his sister passed into the night of shame that has no dawn. Let the beasts thoughtlessly cast their young upon the bosom of nature, to struggle and succumb, but not man. He should think beyond the passions of the flesh, and not curse a child with misery to satisfy an animal instinct. The rule of the married should be to invite no guest until they can be entertained; no children until they can be cared for. To do otherwise is to confess the animal stronger than the human.

If a man toils with his two naked hands to support a wife and family, he fights the bravest battle that is waged on earth, the battle of love. No honor awaits him, no high office beckons him on. Bent, like a beast of burden with daily toil, he struggles to fill little mouths and shoe little feet. He is my hero, and, I think, the bravest and noblest of our kind.

But what must be his feelings when he realizes he is raising some little white slaves, to toil for masters as he has toiled? He struggles and multiplies, and gives his children to the insatiable jaws of greed.

No state is civilized which permits a condition that gives one man as a slave to another. The combinations of incorporated business have robbed the child of his birthright before he was born, and doomed him to servitude. These combines have taken the necessities of the world, the coal, timber and metals, and finally are getting the lands, and, aided by unjust laws, command the State to enforce their edicts of slavery. This is done, largely, by the aid of the United States Senate, whose members often grow fabulously rich through the graft of corporations and trusts.

If the prisons had their dues the Senate would likely fail to act for want of a quorum.

During the last financial panic I happened one day to be in a dining-car where there was a millionaire Senator, reputed to be the friend of railroads and express companies. The dinner cost a dollar. It was a rainy, cold day. Looking out of the window I saw the section hands rush to the track to work as soon as the train passed. These poorly-clad, wet and cold men received ninety cents a day for labor. Slaves on the steppes of starvation, whose day's wage was less than a meal cost on the train. They, doubtless, were raising boys to be slaves of the same corporation. And yet, we say, "the land of the free!" And then, in the same breath, ask the Lord to forgive us for lying.

When I contemplate the condition of the daily toiler, I do not wonder at his fear of a large family, nor do I blame him for limiting it to the conditions of his income. Let the children of the toiling men and women be few in number and free in body. If toilers, parents, lack the necessary knowledge in this direction, they should consult the "smart set" on Easy street.

Abortion.—Abortion is the most widely-spread and frequently-committed form of murder in civilization. It is the unchristian way that Christian people have of limiting the human output. Bad as this mode of child-murder is, it is at least less shocking than the former means of the Pagans and heathens of India and China had to reach the same end. I think most of us, if we had to choose between prenatal death and a meal for a crocodile of the Ganges, or the baby tower of China, we would not be long in favoring the first. If Western civilization succeeds in persuading the heathens of the Orient to turn from their ghastly and heartless social economy, it will, at least, save the public's feelings. But for every child given by these strange snuffers of infantile candles hundreds, possibly thousands,

at an earlier stage of existence yield up their lives to the instruments or drugs of abortionists. If the United States census could give the number of abortions, the figures would be so appalling that they would make the people doubt their civilization, and question their conscience.

The figures of prenatal murder would, doubtless, surpass the birth-rate. The records of thirty-five women, scattered through the Middle West, as my history shows, gave birth to seventy-four children, while there were eighty-nine abortions.

Though in every community and practiced by all classes, abortion is not the crime of the poor as much as of the rich. Nor is every woman guilty in every class, but such a great number are that it may be called universal throughout the civilized world.

The women guilty of having their children murdered before birth have committed a great crime. They seem to think, or at least assume, that the earlier stages of embryonic and fetal life do not represent human life as at birth, or even after the fourth month of gestation. With some religious people there is a belief that the child has no soul prior to a certain undefined period, and to destroy its life is not, therefore, murder. When religion, as in this case, does not square with science, it leaves its votaries in a maze of superstition, and not always capable of choosing right.

Unfortunately for many of us, the ignorance of youth frequently becomes the faith of maturer years, and when the strength of reason is most needed we have but the timidity of doubt, and the weakness of superstition to lean upon.

By far the greater number of abortions are committed upon married women, possibly ninety-five out of each one hundred. This is because of their still greater predominance in numbers. It is also true that nearly all the illegitimate pregnancies are aborted, while in the neighborhood of half the legitimate gestations are permitted to take their natural course.

While married women have less reason for turning murderers than the unfortunate, wanton or deceived girl, the almost certainty that the affair will remain a sacred secret with the doctor, and all interested parties, leaves little to fear from the law.

This same assurance gives the morally-depraved medical man a chance for a good fee, with the danger attending illegal practice removed. Even if his patient die, she would not be permitted to make an *ante-mortem* statement, and the husband has too much at stake to permit awakening of conscience at such a late hour. It is these conditions that so hedge about the crime when committed at home by the married that gives immunity to abortionists, and defies conviction.

There are families, and not so widely scattered either, in which a physician can not hold the practice if he refuses to commit infantile murder. Be it said to the everlasting honor of one of the world's greatest professions, that the number of abortionists among physicians is much less than is commonly supposed, though greater than it should be. Indeed, one abortionist in the more than one hundred and thirty thousand physicians in America would be one too many.

Many of the laity seem to think that all physicians are abortionists, and readily commit murder for the asking. This view arises mostly, I think, from the opinion, before referred to, that it is no crime, early in gestation.

It is nothing uncommon for some verdant, but unfortunate, female, alone, or with a male companion, to make the round of doctors' offices in a city, looking for a man willing to commit a murder for almost any price, and very much surprised when met with a positive refusal at most places. They seem to think the doctor has a cheap "hand-me-down" lot of abortions, ready for sale at cut-rates.

Country people share this misconception of city physicians' lack of morals to an astonishing degree. Perhaps this is in companionship with their neighbors' opinion about city people in general.

A young woman recently made the rounds of doctors' offices in this city, and was astonished at being refused what seemed to her such a small request as performing an abortion.

Once, when asked by a married woman what I would charge to abort her, I

frankly replied, "three million dollars." "Heavens!" she exclaimed, "Dr. (giving his name) has done the work for me three times, and charged me only ten dollars the first and second times, and five dollars the last time. I thought that pretty steep, but," she continued, "he belongs to our church and wanted to do what was right in prices." I assured her the price I asked was as cheap as I could afford for a life sentence in the penitentiary, and a much longer term in hell after that. She informed me that she did not believe there was any wrong in abortion, and was confident that any doctor would do the work if he were not a coward, and then flounced out of my office.

Left to meditation, I concluded that I would rather be called a coward by a simple, morally lop-sided "female creature" than to be pronounced a murderer by twelve "good men and true" in a jury box.

Surgery and Race Suicide.—The surgeon's knife has done its share in lessening the birth-rate in this country and Europe, France having suffered, perhaps, more than any other European country. Whether this country is surpassed, in this respect, by its sister republic across the sea, is open to debate, since we have no reliable statistics on the subject, as the French have. It is claimed that within the fourteen years, ending with 1900, five hundred thousand French women were rendered barren by the surgeon's knife. This number, if correct, carries with it evidence of heartless and reckless butchery. Perhaps not more than one-half of this number needed the operation, and a considerable number died from the effects.

Of all European physicians, the French doctors are the most daring and reckless. They often cut for the love of cutting. If the women operated upon had attained an average age of thirty years, they would lose fifteen years of productive life. At the rate of three children each, from the time of operation until forty-five, the usual time for menstrual cessation, there would be a loss of one million five hundred thousand babies that were never born. Though this is but a very crude estimate, as many of the women subjected to the knife were, in all probability, incapable of bearing children, it still accounts for a sufficient falling off in the birth-rate to help explain why the death-rate in France has passed the birth-rate, making a greater demand for coffins than cradles.

In America, surgery has run riot for twenty years, and outstripped the world in recklessness and daring. This is the age of ripping women up. It is the discovery of a supposed incurable female disease, then chloroform, the knife, and the coffin. Some years ago it was a neck-and-neck race between the divorce courts and numerous sanitariums as to which would relieve the most women of husbands, or the need of them, with Dakota and Chicago in the lead, pushed hard by New York, while Philadelphia brought up the rear, with the only awakening since the cracking of the Liberty Bell. Accompanying this tripod of destinies shaping human ends, and separating the quick and the dead, are a number of lesser satellites which claim attention. But long since the operating table has outstripped the bench, leaving society more physical than matrimonial wrecks.

While these operations are often needed, it is patent to all physicians that they are resorted to entirely too often. Perhaps the fees accompanying them are potent arbiters in influencing the use of the knife.

The thousands and thousands of deovulations mean a proportionately less number of births.

Since the great majority of women who undergo this operation are of the socially better classes, in education and wealth, the decrease in the number of children is largely from homes where they could be best cared for. Other parents, whose opportunities for the proper rearing of their offspring are not so good, will continue to produce the usual number. This class, from the respectable poor to the slum element, dominating society, must, necessarily, have a great influence, and that not of the best. The only agreeable side of this problem may be found in the fact that the vigorous classes, many of foreign birth, will have most of the children, insuring a strong, healthy population for future years.

The weakly, sickly women, whose inert childhoods retarded development of the vital powers necessary to womanhood and motherhood, failing to produce their quota of children, withhold just that much of weakness and disease from the assets of the sum total of American citizenship.

Life, Atomic.—The life of a living body is one part of it, and drawn from the great world of life, the body is taken from the world of matter. This is not obvious to the senses, but real to the understanding.

I can not get away from the belief that life is an atomic substance. Shall I say some form of matter we do not understand, since we can not see, weigh, nor measure it? It has intelligence, motion, and the quality of sensation used in matter. It bodies itself forth in organization. It has the power and wisdom to build itself a house out of coarser matter. It first makes but one little machine, a cell; then multiplies itself and multiplies its little machines, the cells. This it does by adding another life atom and then dividing the parent cell into two cells. Thus it draws both the spirit and matter from two worlds and builds them into a living house. It is the spirit life we receive that shapes, forms and directs all life's actions. This obtains in the first cell, built by the little spark of atomic intelligence, to the full stature of man. The beginning of human life, in its embryonic form, is when two spirit specks unite and begin building up a form to body forth another life.

Billions and billions of these forms of cell-life are produced by the living male and female bodies that never unite, and, like other disengaged atoms, take their place in their own world. It seems probable that all space is alive with life-atoms, ever flowing out from the great center of all life.

As the amount of energy is always the same, though ever changing, and all comes from the same source, the sun, so, probably, the amount of life is fixed by as immutable laws as those governing energy, and comes from a definite, fixed source. So a human more or a human less means nothing except to himself, his joys or sufferings, and the effect upon those about him. If the matter of his body had never been held in a living form, just a little more would have been somewhere else, as it will be when chemical force gains the mastery over vital force, and the "wheel of life stands still."

So with the spirit-matter that fills our earthly bodies. Had it not tarried in this form it would be part of the infinite measure somewhere, as it may be soon. Yet a little while and what we are will be what we were a little while ago. But, it may be; I want to believe, I do believe, that the association of the life quantity we have becomes personified, individualized, and maintains its personal identity forever. If this be true in physical change, the two forms of life, those which are, and those which have passed beyond, will converge until they meet on a common plane. This is but the suggestion evolution would make for life. To thus complete the journey would not be so marvelous as the journey already taken. It would only be a world with all it contains, evolving from the terrestrial to the celestial. Perhaps more than half this journey is already finished.

From a lifeless, pulseless night, the whispering voice of creation awakened the world to life and its onward march. In the recorded pages of creation we trace the footprints of life upward from the depths of slime and ooze to the glory of humanity.

But yesterday, in geologic time, the beautiful, feathered songster of the air was a serpent, and man a beast. The space between them now and then is less than the measures that reach on to touching of hands, and to hearing songs from other lips tuned first like our own; who knows?

After all, life is a little of the infinite spirit working in clay. After awhile it may not need the vessel.

To view life, its beginning and ending in matter, is to give creation no credit for intelligence, and to presume a Creator working without design.

(To be continued.)

[Written for the MEDICAL BRIEF.]

Poison Oak or Ivy.

BY SILAS HUBBARD, M. D.,
East Aurora, N. Y.

A California subscriber requests that some one will write on the above subject. I agree with said subscriber that there is considerable poison ivy in the mountains of California, which I saw three years ago and also heard a number complaining that they had been poisoned, though I saw none of the poison vine in the valleys; I suppose on account of the valleys being so dry, and needing irrigation. Poison oak and poison ivy are two different things in appearance. The poison oak is a shrub—maximum height from ten to fifteen feet; the green berries on it mature in the fall, and remain green upon it all winter. It resembles, in leaves and bark, an ash sapling, and grows in swamps. By contact with it, it communicates the same kind of poison that the three-leaved ivy does. The cure for both is the same. Prevention is the best cure. Every person ought to be instructed to recognize both, and beware never to come in contact with either. The poison ivy is far more abundant than the poison oak, and therefore is far more dangerous. Both of them grow in every State of the Union. In a semitropical climate like Southern California, they are more poisonous and dangerous than in more northern States. In breaking the stems or leaves of the poison ivy a milky juice issues out, which is the most concentrated part of the poison. The tincture of the green leaves is the part used for medicine. A drop of it rubbed on the back of the hand will there produce dermatitis. A drop of the tincture, well diluted, taken three times per day, sometimes cures rheumatism, also some kinds of cutaneous eruptions, etc. When a person has been poisoned by coming in contact with poison oak or poison ivy, the poison does not manifest itself short of fifteen or twenty hours; then a violent epidermatitis sets in, with swelling and redness, and great tormenting itching, especially between the fingers and toes, and wherever the skin is the thinnest. One writer on the Pacific Coast said the poison oak and poison vine had microscopic thorns which penetrated the skin of the victim to produce the poisonous effects. I do not believe it. I believe the poison is an oily acid substance, and to get rid of the oily acid substance I advise the patient to bathe and wash much and long in hot water, as hot as he can well bear, which liquefies the oil and enables the patient to get rid of it much better than to use cold applications recommended by some; for cold applications and lead congeal the poisonous oil, and thereby retards the cure. A hot infusion of sweet clover with a little sulphate of zinc or bicarbonate of soda in it would be better than pure hot water alone to bathe in, for the soda would saponify and neutralize the poisonous acid oil, and help mightily to get rid of it; or to bathe much and long in hot non-irritating soap water would be an excellent cure. I find by these modes of cure the worst cases are cured within a week.

Some people are immune to the effects of the poison. Some people are poisoned if they go in the field where it is, even though they touch it not. I suppose the poison is conveyed to them by insects which infest the vines and shrubs. I wish every State would pass laws compelling their people to exterminate the poison oak and poison ivy.

BY S. C. MITCHELL, M. D.,
Sedalia, Mo.

Tell your California subscriber to try crystallized carbolic acid, one drachm, and add sweet oil enough to make three ounces. Mix and apply three or four times a day. This is also a good application for erysipelas or small-pox.

BY S. J. SMITH, M. D.,
Lincoln, Neb.

Your "California subscriber" will find hydrochlorate of ammonia, one or two drachms in a pint of water, effectual, cleanly and odorless in ivy poisoning. Apply freely.

After testing many things I find this superior to any other remedy.

322 W. Nineteenth St., University Place Sta.

BY R. W. BOWER, M. D.,
Sheridan, Ill.

In the October number of the BRIEF a California subscriber asks for best treatment for ivy poisoning. In its first stages I use sweet spirits nitre and sugar of lead.

℞ Spts. Ætheris Nit. Dol. .....2 ounces.
Plumbi Acetas.....2 grains.
M. Sig.: Apply freely over affected surface with soft cloth every hour or two till itching and burning sensation ceases.

If poisoning has run on for some hours, or even days, before seen, I advise:

℞ Pure Soft Water.....1 pint.
Fl. Ext. Grindelia Robusta .....4 drachms.
M. Sig.: Apply with soft cloth all over affected surface, and when arms or face are sorely erupted, keep parts covered with same.

BY HARRY BROOKS,
Los Angeles, Cal.

In the BRIEF, page 760, a California subscriber wants a cure for ivy poisoning, and I wish to present to your readers a preventive. A couple of years ago, in Northern California, my wife rubbed some of the following over her face, but omitted the ears; the next day the ears swelled up, but the face was uninjured. The preparation used was as follows: Take a level teaspoonful of concentrated lye and a quart of boiling water. After it cools, bottle it for use. Rub over all exposed portions of the body before going where you are likely to be infected, and repeat on returning home. The ivy is only poisonous when it is in the flowering stage, and when the wind blows towards you, carrying the minute spores into pores that are open through perspiration.

BY J. BOMMER, M. D.,
Rolling Fork, Miss.

I find an article in the October BRIEF headed: "Poison Oak or Ivy." A California doctor wishes to know a treatment for poison oak. This plant grows almost on every stump in the Mississippi delta. It seems to affect some people more or less, while some are not affected at all, and causes an inflammation of the skin, with swelling, and breaks into a running and scabby sore. It affects animals the same way, as they are very fond of eating it in the spring. I have treated it for twenty-five years in the following way: Take a teaspoonful of ipecac, put in a teacup, add boiling water to one-third cupful. Let steep like tea. When cool, apply with a feather or mop every four hours. In most cases, in twenty-four hours it is cured. It takes out the swelling and itching, dries up, and heals quickly. In animals I make the tea stronger, and add a few grains of bluestone, and use mop. When the lips of the animal are swollen, stiff and scabby, they can not eat. After a few applications the swelling begins to soften, and the animal will go to eating, and get well in three days. I mention this about animals so the poor animal can get relief as well as human beings. As this is a burning, itching affection, and sometimes becomes very serious, I would be glad if the doctor would report on this treatment after trying it, and let the readers of the BRIEF put the remedy to good use.

BY A. CLEMENT SHUTE, M. D.,
Pottstown, Pa.

The most common cause of poison likely to be called to treat; however, quite a different poison from that of sumach or of weeds.

For poison ivy the internal administration of the 30 x dilution of rhus toxicodendron, as prepared by any reliable homeopathic pharmacy, in drop doses, or the equivalent in pellets, repeated from one to three hours, is certainly curative in the large majority of patients; in fact, in quite nine out of ten, but the occasional case, with severe idiosyncracy, think this remedy will not reach; will respond but slowly to any other one remedy; it may be there is a general blood condition in these patients that is the cause, and no remedy will do more for such a general defective blood condition than echinacea. Use it in five-drop doses of tincture every two to four hours.

Locally, to relieve the intense itching, sweet spirits of nitre does most good.

Recently a native of India stated that if any one susceptible to ivy poison

would bite off part of a leaf and chew and swallow it, he would never again contract poison from that plant.

This I have not proven, but would like to hear results. The sumach poison, I admit, is a hard one to meet, but the poison from weeds which appears on feet and hands of children in suburbs running among the weeds where there are distinct blebs, form with crusts which gradually enlarge to the size of a dime or even a quarter, and are especially likely to be near the nails, I have found the remedy to be hura brasiliensis, 30 x dilution, as prepared homeopathically, in same dose as rhus toxicodendron for ivy poison, and it has never yet failed to speedily cure.

BY FRANK S. ALEXANDER, M. D.,
St. Louis, Mo.

I read in October issue, on page 760, of a brother doctor who wants to know how to cure ivy poisoning or oak poisoning. Well, there is no difference at all.

In practice we often have to deal with a most troublesome affection of the skin, caused by coming in contact with a vine commonly known as poison ivy, or poison oak, as it is called by most persons in different sections of the country. It causes a violent erythema, with much swelling; intense burning and itching. Here is a prescription which, in my hands, has worked like magic, only a few applications being necessary for a complete cure. I have seen some very severe cases relieved by two or three applications. This simple prescription, which I have used with unvarying success, is as follows:

℞ Plumbi Acetate .....1 drachm.
Spt. Nitrosi Ætheris.....6 ounces.
M. Sig.: Apply on parts affected.

This simple prescription has been so successful in my hands that I hope it will benefit those physicians who have heretofore been unsuccessful in their treatment of this simple affection, as I have found that it is in the treatment of these simple affections that our text-books have given us little satisfaction.

[Written for the MEDICAL BRIEF.]

Some Points Regarding "Appendicitis;" Really a Misnomer—Proper Treatment for Pelvic Inflammations.

BY CHARLES E. PAGE, M. D.,
Boston, Mass.

Another new way of accounting for the greater frequency of appendicitis, of late years, is going the rounds of the lay press just now. "It is said" to be steel-rolled flour, in which minute particles of steel from the rollers are found. The fact of the matter is, the disorder is hardly more common than it has been for ages, and the new name is altogether misleading. It is more properly called by the old name, "inflammation of the bowels," the seat of the trouble being in the colon, and is the result of dyspepsia. The victim is usually one who has been troubled with intestinal indigestion for months, sometimes years, constipation having, in most cases, been in evidence and treated by purgative medicines.

Still another way of explaining the frequency of "appendicitis" is, that the surgeons need the money! One very eminent German physician, in an article in a very regular medical journal, explains the "Craze for Cutting," which has been running riot of late years, attributing it to "the lust for surgery and for big fees;" and no less a light in the medical and surgical world than Sir Henry Burdett, M. D., F. R. S. P., etc., of England, on a visit to this country last year, said some very strong things about "the craze for operations." "What we want," he declared before a meeting of medical men, "in every country, is a voice in the mouth of every great surgeon who, with the wisdom to be conservative, has the courage to protest against this ever-growing tendency to put a knife into everybody on the smallest possible pretext."

As for the alleged uselessness of the vermiform appendix, every bed-rock student of hygiene and physiology scouts the notion. A few years ago a thoughtful physician out in Pennsylvania expressed himself pretty plainly in opposing the prevailing idea that the appendix, if it ever had a function, had outgrown it, so

to say. He insisted that it was a useful organ, and he called it "the little oil can of the colon;" and the eminent Sir Wm. McEwen, M. D., professor of surgery of the University of Glasgow, approves of the appendix, and has set his face against appendectomy. He explains that the cecum is an important digestive organ, and that it and the appendix are thickly lined with glands which secrete a digestive fluid of great value, when in combination with other intestinal juices. The appendix, he says, also pours into the ceeum large amounts of mucus highly useful in lubricating the alimentary bolus, and at the same time repressing the development of injurious bacteria. Dr. McEwen calls attention to the almost universal pre-existence of indigestion in cases of "appendicitis," and also to the fact that those who have lost the appendix are, as a rule, thenceforth subject to ill-conditioned bowels, either chronic constipation or diarrhea.

Speaking generally, appendectomy is, in my opinion, about as absurd, though vastly more mischievous, as cutting off the little toe in a case of hip disease. Many fatalities result (though not always so recorded) from a peritonitis caused or increased by the cutting.

Inflammation of the appendix very rarely, to say the least of it, occurs as a primary disorder; the beginning of the inflammation is in the colon, in almost every instance. It may and does often spread to the appendix, and in cases in which the colitis and peritonitis are not properly treated, an abscess may form in the appendix. Something like fifteen years ago, the late Senator Cutler, of Morristown, N. J., became ill with violent abdominal pains, and all the alleged symptoms of appendicitis, and an operation was decided upon. A prominent New York surgeon was called in and the patient was put in condition, and the abdomen opened up, and a search was made for the appendix, but, curiously enough, no such thing could be found. He had none! The only possible explanation of the fact was that in a previous attack of peritonitis, two years before, the appendix had sloughed off, and the wound healed safely. Mr. Cutler ever after that chuckled, so goes the newspaper account, whenever appendicitis was mentioned. "I read of a Boston man," he said, "who took the precautionary step, which I think I shall follow. He is said to wear a card pinned to his undershirt, bearing the inscription, 'My appendix has been cut out!' He says he does this to keep the doctors from operating on him for appendicitis in case he is picked up in a fainting condition on the street some day. I think I'll do the same." At the time it was remarked that Mr. Cutler was "enjoying rather a grim joke at the expense of the medical fraternity;" but the really grim joke was at the expense of the victim that paid the big fee for the needless, harmful, and very dangerous operation. It is not at all unlikely that had he been operated on during his earlier attack, and the appendix removed by the surgeon, instead of by the organism itself, that illness would have been fatal.

One moral may be learned from the foregoing, viz., the removal of the appendix, even when done by nature, does not prevent, but really renders more likely, pelvic inflammations, for reasons indicated in Professor McEwen's explanation as to the function of the appendix.

As to the appropriate treatment for all pelvic inflammations, there is but one, as it seems to me, and that is about as follows: Therapeutic fasting is demanded, as is true of all acute diseases, until convalescence is fully established; then, and then only, is food anything but a drug, and an ugly drug at that, since only indigestion and blood-poisoning from the absorption of putrescence from the alimentary tract, can result from ingesting even the most wholesome food into a stomach which is, for the time being, absolutely incapacitated for digesting anything; water being the sole nutriment demanded. It is well to have the patient take a small half-cupful of moderately hot water as often as every hour or two during the daytime, in order to maintain proper fluidity of the blood, which otherwise can not do its normal work of healing. The cold compress over the whole region of the abdomen is just the right thing, and is deliciously soothing when rightly managed, as follows: Two folds of coarse

towel wrung tightly from cold water (usually, ice water, especially after a few applications of the compress wrung from cold water), and placed over the entire abdomen, the damp folds to be freshened as often as they get hot, and long before any approach to dryness is observed. In some cases the changes will at first be made as often as every ten minutes, and at lengthening intervals, as the inflammation subsides. Over the damp folds as many folds of dry towel are placed in every instance. The use of ice directly to the skin is brutal and mischievous, but only good can come from the cold compress, as above indicated. The same treatment is indicated in all pelvic inflammations, whether the disease be puerperal fever, peritonitis, ovaritis, or *n'importe* the name. All pelvic inflammations are thereby readily reduced, if managed skillfully at any early period of the disease.

Years ago, I found that stimulants and all forms of drugging were against me in treating these cases. Patients, seemingly, improving under the prevailing treatment only too often suffer a relapse and go down to death, stimulants and forced-feeding being the chief enemies turning the tide against a recovery. In September, 1903, I received a telegram from a young man at Turin, N. Y., describing the case of his sister, twenty-two, attacked with appendicitis, as diagnosed by the family physician and consulting surgeon, and asking me to wire directions for treatment, as it had about been decided to operate on the following day, unless I could accept the responsibility of the case. I at once wired definite instructions for treatment, and there were several exchanges of telegrams, and all confirmed by letter, and the patient was rather speedily convalescent, and her recovery came in due time. In the course of the correspondence I explained certain exciting causes of pelvic inflammations, and directed a wholesome regimen all around, and there has been no recurrence of the trouble, and the young woman's health has been markedly better than it had been for years before the attack. She was a frail person, and two of her sisters had died of consumption, and her friends felt much reason for fearing that her fate would be like that of the others. Certain it is that in her delicate state the contemplated operation would have given her a very close call, aside from the question of the loss of a very useful, and, generally speaking, perfectly inoffensive organ.

120 Tremont Street.

Dianism.

BY J. WATERLOO DINSDALE, M. D.,
Prescott, Ariz.

The teachings of this article apply to all who desire to have sexual health and manly vigor, whether married or single. The facts stated and deduced will certainly prove helpful and instructive to each careful reader.

If possible, before attempting to read or study this treatise, settle it in your own mind that creative functions are a part of the divine plan, and that wisely used, they are in no sense unclean. Resolve to keep them sacred, and to ever treat the subject with reverence. This is a vital step toward health and holiness.

Marriage is the union of two persons of opposite sex, in mutual obligation to each other, to their fellow men and to God; to live in accord with highest convictions of right and duty. True marriage involves a mutual, controlling love.

The success of marriage depends upon the wise, intelligent, loving association and harmonious relations of husband and wife in all duties and pleasures that pertain to life.

Obedience to the laws of sex and to the laws of love will make marriage a true union of physical and spiritual natures, and dispose of the query: "Is marriage a failure?"

It is not too much to say that there is a rapidly growing sentiment in favor of wise self-control and the conservation of vitality by the observance of chastity and continence.

The question arises and has arisen in almost every married person's mind: Why is marriage so unsatisfactory when courtship was so delightful? Can the beautiful, lover-love of courtship be taken into and preserved through married life?

The doctrine of physical necessity and the subjection of woman to man's desires are a part of the gospel with some people. That the former is a delusion, and the latter an injustice, it ought to be easy to prove.

The following declaration seems to indicate that the dangers from a chaste life are purely imaginary—without any real foundation:

"In view of the widespread suffering, physical disease, deplorable hereditary results, and moral deterioration inseparable from unchaste living we the undersigned members of the medical profession of New York and vicinity, unite in declaring it as our opinion that *chastity—a pure continent life for both sexes—is consonant with the best conditions of physical, mental and moral health.*" (Signed by leading physicians of New York City and vicinity.)

Sex desires are natural to the normal individual, but unless offspring is wisely designed, and wished for, sex desires must be controlled and directed. It is a scientific fact that the natural productions of the sex functions, stimulated by desire, and not wasted in indulgence, are reabsorbed into the system, through the circulation of the blood, and surprisingly strengthen the physical, mental and spiritual natures. On the other hand, their loss, through whatever source or cause, has a decidedly weakening and depressing effect.

Another evidence that seems conclusive against the "physical necessity" claim, is the practical agreement of all reputable writers and thinkers that up to the marriageable age there should be purity of life, abstinence from all physical sexual excitement. If this universal view is well founded, it is probably one of the strongest arguments in favor of marital continence and against "physical necessity" that it is possible to deduce.

From the age of puberty boys and girls are uniformly expected to live continently until marriage. This requires an average of at least ten years of abstinence in each life, at a time when habits are being formed, and when, for the uninstructed, abstinence is most difficult. If the demand is a just one, and the young folks can maintain virtuous lives during this most trying period, it is clear that the doctrine of "physical necessity" is an erroneous one.

Up to the years of puberty the organs of sex are undeveloped and inactive. Soon after this phase of development occurs, a marked transformation takes place throughout the entire physical organism. The voice changes from the shrill treble to the manly bass or musical tenor; hair appears on the face and body, the muscles become firmer, the form more angular, and the skin, which has been delicately soft, assumes a coarser, stronger appearance. Even "the mind acts with new vim and brightness." "And all this because the testicles develop normally and secrete fertile semen, which, being again *reabsorbed* (not lost or wasted) into the general system, and by reason of its reflex stimulating influence over the *entire* system, enables a youth to stand up like a creature of God." (Dr. Sperry.)

The principles of the Golden Rule, and the law of love taught in the Scriptures, clearly prove that the subjection of woman is an injustice. That maternity should, on any pretext, be forced upon her, is an intolerable injustice. If woman, the person most directly concerned, is not allowed to decide this matter, it is very certain that no man has a right to determine it for her. What man, with a spark of liberty in his breast, would submit, were it possible, to having maternity, with all it implies, forced upon him? How, then, can any manly man, with the Golden Rule in view, advocate the subjection of woman?

If these conclusions are correct, and the exercise of procreative faculties is confined to the times when offspring is mutually desired, what is to be done with the imperative demand of the physical nature? Crucify it, starve it, kill it, have been some of the answers of the past, but the effects have been similar to destroying the will of a child—little worth saving is left. What is the true method?

As sexual attraction begins in early childhood, before procreation is possible, and, as in courtship, brings satisfaction without any physical contact, it is evident that there is at least another mode of sexual satisfaction besides the procreative. Indeed, the higher functions of sex are

mental and spiritual, and the procreative should never be used except with the free, full approval of the two higher.

That all excesses and perversions are abnormal is a self-evident truth. Excessive generative desire is a product of *incontinence in thought or life.* It is greatest when there has not been time for over-accumulation; and the longer the period of continuence is maintained the less will be the abnormal desire.

The satisfaction derived from intimate and pure sexual association, dispels the generative desire; while the repression of either creates a demand for the other. The physical remedy, therefore, for sexual incontinence is to be found in the full satisfaction of the affectional function, in pure and intimate association; and for those who have not the privilege of sex companionship, in directing sex forces into mental channels of activity, always exercise the affectional function mentally in preference to the generative.

Sexual satisfaction is to be obtained in all degrees of loving, harmonious association—even from affectional thoughts, personal presence, and each form of personal contact up to the including generation. As mental and spiritual enjoyment of sexual companionship is superior to physical pleasures, as it is also more lasting, elevating and ennobling, it should be the object of the married pair to live as chaste lovers.

Humanity, being the culmination of all past generations, it is impossible to decide upon an exact dividing line between normal and abnormal tendencies. Thus the desire for sexual companionship, that is pure and natural, and needs only mental friendship to satisfy it, may, through misunderstanding or erroneous teaching, be diverted into feelings and desires which are the opposite of love. One who has perverted his faculties to sensual, selfish purposes, has thereby dulled his sense of equity, and is not in condition to appreciate the higher enjoyments that come from noble living.

It is most important to recognize the sacred character of sex in each of its normal relations. Failure to realize satisfaction in purity generally arises from ignoring the affectional functions of sex. In order to live purely men and women have thought it necessary to deprive themselves of sexual association and companionship. They have thus given this important part of themselves no opportunity for normal exercise or development. This abnormal state has a tendency to make virtue difficult, and results, usually, after a season of restraint, in some form of excessive sensuality. Such people are ready to declare that purity is an impossibility, when the simple truth is, they have been living abnormally. The remedy is to be found in the exercise of the affectional principle of the sexual nature in pure and sympathetic companionship.

What is it that distinguishes a thief from an honest man? One has accustomed his mind to covetous thought—to look upon the property of others with an intention to possess it unlawfully. The other maintains an opposite state of mind. The difference, therefore, is narrowed to that of the habitual mental state of each toward the property of others. What is it that distinguishes the normal man sexually from the sensualist? It is evidently the habitual mental state of each respecting the opposite sex. The normal man looks upon woman as a gift, and equal, a companion for highest soul communion, for sexual satisfaction through the affectional nature, and when wisdom, love and mutual judgment dictate, as possible and honored mother. The sensualist being ignorant of the law of life and the dual functions of sex—the affectional and the generative—looks upon woman as a means for mere physical gratification.

Men and women have only to constantly endeavor to entertain these ideal (true) thoughts concerning the opposite sex to reach the truest and most lasting happiness that can come from the association of the sexes. As they undertake to do this they will find that other thoughts will occur to them with less and less frequency. Indeed, new brain-cells will be formed, and the true lover-love developed in all its divineness.

Physical contact without spiritual harmony is always very unsatisfactory. This is doubtless the reason for many very unhappy lives—the insistence upon marital right—that of spiritual companionship, and the satisfaction of the affec-

tional functions of the sexual nature—is entirely overlooked. The continuance of such a course means the destruction of love. Indeed, the preservation and conservation of true love in married life requires that *neither shall insist upon what the other can not willingly grant.* This is one of the rules observed by Mr. Gladstone and wife, and to it he attributed, in large degree, their happy married life. The principle is especially pertinent in all that concern sex relations.

Those who do not understand the turning of passion into affectional currents, will find purity of thought and life impossible.

The law of sex, when properly understood, means the elevation of the individual and the truest happiness in the married state. Those who imagine that the law will deprive them of pleasure should understand that new, truer pleasures result from keeping the law than can possibly come from breaking it.

One of the most frequent objections to a continent life is that it deprives the married pair of the love manifestations which accompany physical union. Every person who has practical knowledge must admit that the highest form of love experience does not depend upon the culmination of physical union. That love is not an essential element of physical union is abundantly proved by the almost utter lack of love in what are termed illegal relations.

All the real love manifestations are intensified by the wholesome methods herein advocated, so that the reverse of the objection is true.

Many advocates of continence depreciate the importance of the sexual nature, and look upon it as something of which to be ashamed; but this erroneous view is by no means a general one. Wise continence is not a depreciation, but rather an exaltation of all that properly pertains to the sexual nature. As in all the lower forms of animal life this faculty is restricted to the purpose of reproduction, so, in the human economy it should be held sacred to its clearly-defined uses. It should be plain to those who fail to find satisfaction in abnormal practices that something is wrong. Why, then, should they not turn to the course indicated by nature, science and religion?

The principles herein advocated do not forbid the exercise and use of the sexual nature in normal—the affectional, and the building up of mental and spiritual forces—but the waste of vital elements through abnormal and perverted practices, both mental and physical.

A potent reason for abstinence from the generative function is the fact that during pregnancy and lactation the normal woman has little or no desire for creative association, while her nature demands, and the best interests of the child require, the loving, sympathetic and careful attention of the husband and father. These attentions, in the right-minded, will not tempt to mere sensual indulgence, but will lead to the higher, nobler, spiritual and harmonious relations—elevating, inspiring and thoroughly helpful.

It is asserted quite generally now, that woman should always be free to determine when she shall accept the parental office. It is not amiss to say that desire for parentage should be perfectly mutual, and justice demands that so important an office should not be thrust upon any one.

"Always should the deep, pure instincts of woman guard the door of the temple of God when He causeth the beginning of a young immortal to arise." (J. H. Jones, in "Perfect Good in Wedlock.")

These considerations put a decided premium upon self-control, and clearly indicate that the sex feelings should not assume the creative condition except when parentage is mutually desired. Until this time sex force should be directed into affectional and other uses.

It has been taught by some that through wise continence the vital fluids are transmitted into brain and muscle, giving new energy to the body and keen, clear perception to the mind, and it is safe to conclude that the methods herein advocated lead directly to these desirable results.

The fear of impotency from lack of procreative use is a groundless one. Most eminent physicians have positively asserted that they never knew a single case of impotency to result from continence, but all were the result of perversion, excess and waste. The seminal secretions

are analogous to the tears, being secreted and expelled only on occasion, and losing nothing from abstinence. Besides, there is always ample opportunity for the normal exercise of the affectional functions of sex to preserve a healthy and vigorous condition.

Many pages of Noirot's works are devoted to showing that continence prolongs life, while incontinence hastens old age.

"The canary, if permitted to raise offspring yearly, lives not more than eight or ten years, while the celibate bird has survived twenty-two years." (Hervieux.)

Persons who have accustomed themselves to wasting their sexual secretions in any way, will find the return path to normal life a more or less difficult one, according to the strength of the habit and the impairment of the will which always results from the waste of sex vitality.

To remain continent, to turn the current of life inward instead of wasting it, to direct its beneficent force in channels of affection, and use it to build up and enrich the entire system, will, until the mechanism of the body recovers its normal condition, cause more or less effort and inconvenience. But the result will be worth infinitely more than the cost—victory over enslaving appetite, perfect self-mastery.

Medical Treatment of Sterility.

BY ELI G. JONES, M. D.,
New Brunswick, N. J.

About one woman out of ten is sterile, two-thirds of the cases of sterility we meet with are caused by displacements.

Not long since I read an article on treatment of sterility, where some thirty or forty different remedies were recommended. All this is confusing to the busy practitioner. A good mechanic only needs a few tools. I shall mention just a few remedies I have used in nearly forty years' practice.

To make this a practical article I will illustrate it by some cases I have treated successfully:

One evening, after my office work was over, a gentleman and lady from New York City called to see me. They were quite wealthy and they both longed for children. Various remedies had been tried, and different means used to accomplish the result, but conception did not take place. Upon making a vaginal examination I found a profuse leucorrhea. We know that the natural secretion of the vagina is slightly acid. In this case the blue litmus paper dipped in the discharge showed a deep pink color, showing an excess of acid, enough to kill the spermatozoon after each connection.

This, then, was the cause of the sterility. I had a tampon made of soft linen cloth, wet with one drachm of phosphate soda in one ounce of glycerin, placed this in the vagina once a day for three days, then let the husband have intercourse with his wife. In two months from that time I heard from her husband that they had reason to believe that conception had taken place. Later on, she gave birth to a healthy child.

Another lady had become pregnant three different times, but she always lost it within two or three months after conception. I found, upon examination, an induration of the neck of the uterus. In such cases sterility nearly always exists. I used tampons of ammonium sulpho-ichthiolate and glycerine, equal parts, placed up in the vagina against the mouth of the uterus, once in twelve hours. Gave her arum. mur. nat. third decimal (chloride of gold and sodium), three grains one hour after each meal.

With the above treatment I removed the induration, and she became pregnant in about three months after commencing the treatment.

In another case the couple never had had any children. The wife complained that she took no pleasure in the sexual act, had no desire whatever for her husband's embrace. The editor of one of our journals, writing on this subject, made the statement that enjoyment of the act of sexual intercourse has nothing to do with conception. I beg to differ with him, for I know, by many years' experience, that the most passionate women are the most apt to conceive. In the above case I found no induration of os uteri, no menstrual discharge from the

vagina. Just a plain case of frigidity. I prescribed fluid extract of saw palmetto, twenty drops in water, three times a day. Then told her husband not to offer to have intercourse with her for a month, on the last day of her monthly period to have connection with her. After the act have her lie perfectly still and cross her legs, elevating the hips. In a month's time, under the saw palmetto, she was ready to welcome the husband's embrace, and, as he followed my instructions, she did not menstruate again, for conception took place, and, later on, she presented her husband with a boy.

Still another case of a lady who had never had any children, though married several years. She complained that her husband did not satisfy her in the sexual embrace, and she had become very much disgusted with her married life.

A further investigation of the matter developed the fact that as she was quite fleshy and her husband's penis a short one, the head of it did not reach the os uteri, and conception could not take place. I then advised the couple to change positions during the sexual act, and to have connections on the third, fifth and seventh day after the monthly period. In three months time she reported herself pregnant, and later on, gave birth to a child.

In one case of ante-version of the uterus, I advised sexual intercourse standing up on their feet, and conception took place.

In the case of a lady with an *irritable* clitoris, excessively passionate, I prescribed monobromate camphor, two grains three times a day, to overcome the irritability of her clitoris. In a month's treatment she reported herself very much better, and a few months afterwards she became pregnant.

As a tonic for a woman when her sexual passion is weak, I like the saw palmetto. It is an *ideal* sexual tonic.. A careful study of our *materia medica* will discover valuable remedies having a positive action upon the uterus, and with them we can cure the different forms of displacement of the uterus without the aid of pessaries, supporters, or any operation. I know this to be a fact, for I have cured such cases "many a time," but that is "another story," and must be told in another article.

When you have a case of sterility, try to find the cause of it, and remember that a large proportion of such cases may be cured by a little medicine and good common sense.

Man.

BY E. E. GILMORE, M. D.,
Adrian, Mo.

The essential study for us is man. In order to properly qualify a physician to follow his chosen profession, he should be made thoroughly acquainted with man, and the vital laws that govern his construction from the union of the atoms in the female womb to his death; not only his size, form, motor and intellectual forces, but his origin, development and final destination. He should be able to count the elements, simple and compound, which are essential to his construction, and the vital force that arranges them into his beautiful, intricate and wonderful body. Like all other organic bodies, he is constructed out of material elements by the biol or ethereal force that permeates the universe. That force is not a compound, but a unit simple, and is the power that constructs every organic body that exists. Every material body, solid, semi-solid, or liquid, that exists in space, was brought into existence by that simple force uniting the original simple elements and condensing them into bodies. The manifestation of that simple unit force is seen in the revolving worlds, as they roll in magnificent splendor through space, as well as in every organic body, from the starch granule to man, and it, by some, is called God, whose cosmogony ceased at the end of the sixth period.

When the first period began and the sixth period ended, I do not know, yet we know that things exist as they do now, and must have had a beginning. We recognize man as the highest type of organic beings that occupy this sphere of existence. There may be germs hidden in ether that have not yet been brought by

natural force into the essential environments to generate the constructive force to start up the metabolic changes of the essential atoms holding in potentiality the central essence which, when initiated, might develop a different and higher being than man. Perhaps, away down in the future periods to be counted by the revolutions of the earth, a different class of animals may occupy this land of ours, and a higher and nobler race of people rule where we are now supreme.

Our most important study is self; for a thorough knowledge of our organism, its synergists and incompatibles, is the essential equipment of the physician, which will enable him to fill his place in life honorably and with dignity.

Man, as a being, is a unit in the universe, yet in his construction he is a universe in himself. Our organism is built up with cells. The soft tissues, muscles, bones, the enamel of the teeth, are builded out of cells. Each cell is an independent unit, and has a specific duty to perform. One group builds the muscles, one the bone, and one for every department of the structures of the body. Each group of cells is equipped, prepared and endowed with the essential skill to enable it to construct out of certain material a definite structure. Therefore, we have a brigade of cells to build the nerve structure, one for the muscular system, one for the osseous tissue, and one for each distinct tissue of the body. They are mechanics, each qualified to do a certain part of the body-building. The brigade that builds the nerve can not construct the skin, muscle, tendon, bone, or any other part of the body, except its own.

The cells are divided into three brigades, the carriers, the mechanics, and the scavengers. The blood cells are the carriers, and number nearly seventy-five billions. They receive the material and convey it to every part of the body, to every organ, and also gather up the rubbish, waste material such as can not be used, and carry it back to the outlets, and it is dumped as garbage. The little mechanics take from the blood just such material as they need for the structure that it builds, and reject all the rest. The scavengers are the police, who guard the inner parts of the body, standing guard over the blood cells and the mechanics, ready to arrest any intruder that enters; and, when the bacteria, or any foreign life unit, enters the circulation, they immediately move out and attack them, destroy them, and their dead remains are carried out of the system by the blood. Should the invading germs outnumber, and be stronger than the phagocytes, they will conquer, and death to the organism results, but if the phagocytes are in the ascendancy, they conquer, and the organism assumes a normal condition, and life continues.

What a grand scene to contemplate, when you stand and look at man, in the full vigor of life, and contemplate in your mind his wonderful structure; take him apart, look at his muscles, bones, nerves, glands, all separately in your mind; you look at him as a unit, then view in your mind the seventy-five billion of unit blood cells, and at least one trillion five hundred billions of the little unit cells at work building and repairing that human unit, each of which never ceases work, never rests, but are constantly on the move! Each of these cells is a unit life, and they are just as essential to the universe as man. Then watch the phagocytes every day, perhaps, as they march out to attack an invading enemy, watch him pounce upon the enemy and strangle him. Many of these conflicts, unseen by us, are grander than the battles of Sebastopol, Antietam, Lookout Mountain, or any battle fought by man. Were it not for these little cell-life units, the human family would be exterminated, and all the grandeur and splendor of arrogant man would go out.

Then, the essential study of the physician is man. This embraces anatomy, physiology, pathology, and therapeutics. Anatomy is the basis of his knowledge; for no one is capable of taking care of a machinery without being familiar with its intricate structure.

Then comes physiology, which teaches the function of each part and structure. Then physiology is an essential study for the physician.

Then, when the physician becomes thoroughly acquainted with anatomy and

physiology, he is ready to study pathology, which means the condition of the organism in every deviation from a normal state. In the study of pathology, it includes bacteriology; for, if we discover an abnormal state, we should know the cause of the change in the organism. Then the study of bacteriology is one of the very essential studies of the doctor; for a knowledge of bacteriology is essential to the proper knowledge of pathology.

Therapeutics is also an essential study for the physician, because no physician should ever give a dose of medicine without knowing its effect upon the human system. If he does, and gives it not knowing why he does, he is a fraud. Chemistry is one department of therapeutics, and when we speak of a physician's studying therapeutics, we mean that he should also study chemistry.

The knowledge the physician wants is that which will qualify him to superintend the human being in health, direct and instruct him how to avoid disease, and, if sick, he should be able to recognize the conditions and its cause, and then apply the proper remedy to restore him to health. The physician stands on a higher plane of honor and dignity than to be a money-grafter at the expense of the sick mortal, and administer to him solutions and compounds, of which he is ignorant, and has no conception of their effect upon the individual. It is theft to do it.

Then the proper field of study for the physician is anatomy, physiology, pathology, and therapeutics. Theology, astronomy, geometry, trigonometry, Latin, German, French, or any other language, except the English, is of no use to him, for every scientific fact known to man can be learned in the English language. In fact, the English-speaking people lead the world in every department of science, and I do not think that the American youth who wants to study medicine should be required to waste his time over these languages, especially the Latin language. How degrading to our race to see a little ten-year-old child in our common schools with a little Latin grammar in his hand. It is an insult to the American student and to our race, to force it on any American youth.

Medicine rests upon a scientific basis, and is governed by natural laws, immutable and inviolable. We have medicines that will stimulate functional activity, and others that will decrease it. Certain substances will increase the motor force of the heart, and others will diminish it. One medicine will increase the action of the kidneys, and others diminish it. So it is with every function of the body. We know that we have medicines that will increase or diminish the action of every organ in the body, and there is another point just here that is vital: a medicine that will increase the motor force of an organ will not decrease it. Then, it is very evident that no one medicine or compound will act as a rémedy in all conditions of the organ. These patent compounds, which are advertised to cure heart, kidney or liver troubles, are frauds, for the term "troubles" does not mean anything. Every patented compound should be banished from society, and these advertising "fakes" should be driven out of the country, and let common sense and intelligence rule supreme. Let man come to know himself, and with the scepter of that knowledge he can sway and rule the world with a reign of wisdom brighter than yet dreamed, and more glorious than yet imagined.

Can Tuberculosis be Cured by Electricity?

BY NELLIE M. JOHNSON, M. D.,
Perry, Iowa.

What is our therapeutic mission in tuberculosis? To enhance the vitality, to arouse the resisting capacity of the patient, and render the organism immune to the onslaughts of the bacillus.

Exercise is a much valued element of bringing about these results. What is to be done in acute cases? The patient is put to bed; we direct good nursing, diet, and baths; exercise is out of the question. Until we obtain an antitoxin which will destroy the tubercle bacillus, we must endeavor to do the next best thing, viz., en-

hance the resisting capacity of the patient. Static electricity has revolutionized the treatment of these cases. This method, of course, includes climate, rest or exercise, diet, bathing and feeding.

When seen in the early stages and under favorable conditions, it has been the writer's experience that very much, constitutionally, may be done for consumption.

But if the case has advanced to any considerable degree, and the patient is compelled, by circumstances, to remain shut up a better part of the time over sewing, or over a desk, the conditions are very unfavorable to any form of treatment. Little can be expected, except in a change of climate.

Events transpiring during the past year have awakened a new interest in the employment of electricity in medicine. The publication of the successful employment of electricity in the treatment of many conditions has caused many to give it consideration who have, heretofore, absolutely ignored the fact that electricity, in any form, was of therapeutic value, except as they would recommend it in hopeless cases.

When the patient's diet, work and exercise can be controlled by the physician, and, if too much destruction of lung tissue has not already taken place, the author has been led to believe, by the successful treatment of three cases, treated by electricity, that even in this climate, cases of consumption can be cured by daily treatment.

Treatment.—Go over surface of chest daily, for a time, with the high frequency, not over twenty minutes' duration, followed by thirty minutes' insulation.

The patient shows improvement, first by coughing less, night sweats diminish and finally cease, appetite improves, color and strength gradually return, and the patient will soon volunteer the information that he is improving.

In addition, it may be truly said that few measures in the armamentarium, medical or physical, offer so great possibilities for the relief of human suffering as static electricity scientifically applied.

Its application is limited to no specialty, and no specialty is complete without its addition as a means of relief.

Producing, as it does, the X-ray, with all its possibilities as a therapeutic agent, added to the therapeutic effects of the various static modalities, makes the static indispensable to the up-to-date physician and surgeon.

A Rational Treatment of Senile Endometritis.

BY ERWIN REISSMAN, M. D.,

Assistant to the Department of Surgery, Good Samaritan Dispensary, New York. Newark, N. J.

The presumption that women past the menopause are not prone to uterine inflammations is erroneous, but this seems to be a fixed belief with the laity, and some medical men. The belief, also, that chronic uterine inflammations are past cure is equally wrong, and such belief is largely due to ineffective attempts in dealing with them.

A very prevalent affection of women past the climacteric, is senile endometritis, and the practitioner who will appreciate the importance and gravity of this uterine inflammation will soon discover enough evidence upon examination to warrant his looking for an effective remedy.

It is well known that women in general only reluctantly consent to vaginal examinations, and particularly is this so with women who, in their younger days, have not suffered with uterine disorders. In such cases it is well to have in mind conclusive and convincing argument to impress them with the necessity for examination and treatment. I believe that in many cases the unpleasant as well as painful symptoms will materially aid in obtaining the required consent.

Some three years ago, while assistant in the gynecological department of the New York School of Clinical Medicine (Dr. A. H. Goelet's service), I observed many cases of senile endometritis which were effectively cured by a simple method, first employed and described by Dr. Goelet. Since then I have had the satisfaction of relieving a number of patients of this troublesome disorder by this very method.

The etiology of this chronic inflammation may be a neglected endometritis during the menstrual life, but it undoubtedly is the result of the atrophic changes which the uterus undergoes during the menopause.

A deteriorated condition of the general system also plays an important part.

Pathologically, we find an altered condition of the glandular structure and the secretions, a complete change in the character of the epithelium of the mucous membrane, and at times a complete disappearance of the latter.

There is a general contraction of the uterus, a narrowing of the cervical canal, with an eventual obstruction or obliteration. I have seen cases where the mucous membrane was entirely destroyed, in places, by the acrid discharge, and the result was the formation of cicatricial bands, not only involving the cervix, but attacking the vagina, and so narrowing the vaginal vault as to entirely obliterate the cervix.

In appearance the vagina is particularly characteristic. The surface is pale, almost white and glistening, in some spots there are red papillæ, consisting of capillary vessels, demonstrating destroyed epithelium. Sometimes the vagina appears inflamed and covered with muco-purulent discharge, intensely acrid, causing a vulvitis extending to the thighs and rectal regions.

The discharge varies in character from muco-purulent to sero-purulent, according to the duration of the disease.

The symptoms of this condition are variable.

The patient will complain of headache, simulating a burning on the top of the head; a burning in the lumbar and sacral region, rectal tenesmus, and vesical tenesmus, the latter more frequent.

At times there is a chronic cystitis and urethritis, with a urethral discharge.

Impairment of digestion, with evidence of malnutrition, is a frequent complication.

The general health is poor, the skin is dry, there may be nervousness, sleeplessness, and mental depression.

In women past the climacteric, manifesting the above symptoms, a diagnosis of endometritis can be safely made, and an examination should be insisted upon.

Treatment.—Dilatation of the cervical canal, with the consequent promotion of free drainage, is the simplest and most effective method of treatment. How to accomplish this without doing injury is the most important point.

Forcible dilatation of the canal with steel instruments may result in rupture of the cervical tissue, as the cicatricial bands will not yield. Curettage of the uterine cavity is not called for, if the mucous membrane has already been destroyed by the acrid secretion. The same applies to caustics and irritants. In the early stage of senile endometritis, a short time after the menopause, the above methods, if carefully done, are very useful, but later they are injurious and useless.

But still the requirements for a cure are the same, and in order to maintain a canal sufficiently dilated to obtain free drainage, and to admit of repeated irrigation, necessary for an aseptic condition, some plan must be adopted which will favor this result.

In such cases, the negative pole of the galvanic current, inserted in the uterine cavity through conical electrodes of gradually increasing size, is one of the most satisfactory methods of treating this most persistent and chronic gynecological disorder.

By using a moderate strength of current, five mm., a possible destruction of the tissue is obviated. When the proper degree of dilatation is accomplished at each sitting the uterine cavity should be irrigated with a weak alkaline solution.

This dilatation and irrigation must be repeated every two or three days at first, then at longer intervals, as improvement takes place. It is important that the entire vulva and vagina be kept in an absolute state of cleanliness, which is easily done by instructing the patient to irrigate the vagina daily with soap and water, and a fountain syringe.

While these cases require weeks of tedious treatment, which might become burdensome to both the patient and the physician, nevertheless the result produced will fully recompense them both for the time and labor expended.

39 Wright Street.

Human Perfection.

BY D. W. LOREE, M. D.,
Ridgeway, Mich.

While but few have any adequate conception of what constitutes a perfect man, it is pleasing to the average mind to believe that man is the noblest work of God, that he is fearfully and wonderfully made, that he is an image of Him who presides at the Supreme Court of the Universe; and especially pleasing to believe that he has capabilities and powers of endowment which qualify him for an endless advancement in knowledge and happiness, with opportunity to profit by his ever-increasing store. While this may be true, it would seem not to be of universal application. As we look abroad we behold on every hand scenes of suffering, misery and degeneracy, sometimes without even a mark of nobility, and with the divine image so blurred and defaced as to give no hope under present conditions of servitude to death. Even after six thousand years of human history, there is not a man upon earth, in his right mind, who for himself would claim either physical, mental or moral perfection.

Perfection implies perfect human nature, with mind and heart in full harmony with principles of righteousness and the golden rule, with capacity to reason rightly, wisely in respect to the laws of that perfect life, and with an obedient heart up to the full measure of a perfect man's ability. But so long as the world of mankind are on the toboggan slide of death because of sin and selfishness, wherein shall we center hope for the ultimate attainment of, or restitution to, perfection of life?

Its attainment implies a return from this deathward sweep, upon a plane of increasing sliminess, from this dying condition of sin and selfishness, up to full perfection of life here upon earth. With this view of the situation, and with a full appreciation of the term "human perfection," all must agree that death must be abolished before the goal can be reached. Is there a member of the race who can hope to reach that high estate without some further demonstration of divine power than the world has yet known? And can that demonstration be anything less than such a shaking of human institutions and sifting of human philosophies as will bring the world of Christendom upon bended knees, with all tongues confessing to the glory of God, for the perfection of His character, in wisdom, justice, love and power?

Perfection of nature, physical, mental and moral, is a possibility for the great majority of mankind, while not a certainty for any; because its attainment will require a reign and rule of righteousness in mind and heart, as well as a right use of every reasoning faculty, and wisdom from a source beyond that which nature can supply. He who claims nature for his only God has a God without sentiment, and fails to reason rightly. He reads the book of nature imperfectly who fails to catch a glimpse of nature's God, from whom alone cometh the "spirit of a sound mind." Soundness of mind, as exemplified in the right use of reason, is one of the first steps towards perfection.

But the man must have such an appreciation of the prize as will lead him to desire it, and to put forth an effort to obtain it, by a hearty submission to all requirements necessary to enter the race.

It is well to remember that because of prevailing and long-continued human *imperfection*, and the unhappiness of mankind, that the world is yet very much in darkness as to the ultimate outcome.

Civilization's high degree of development, through discovery and human research in bringing the elements and principles of nature into use is so wonderful, so amazing, as to blind the eyes of the understanding of the busy world in respect to that "true light" which is yet only as "a light shining in a dark place," "a lamp to the feet, a lantern to the pathway." Some one has truly said that the world of mankind—"the groaning creation"—are like children crying in the night time, waiting, watching, hoping for the coming of a new day.

We have abiding faith in the teaching that the first man came into being as a "Prince of God," in full perfection of life, capable of living everlastingly upon condition of daily receiving a supply of life-

sustaining elements, and continued obedience to the law of his life, the will of God, with whom he had communion and fellowship and instruction, which qualified him to discern as between right and wrong in their application to himself and others; that he was made acquainted with the baneful results of evil, and of the blessed results of righteousness; that he had freedom of choice, or will, in regard to his own conduct, though, practically, without experience in the affairs of life.

It is not to be supposed that the progenitor of the race had all the intellectual grace and moral refinement here and there exhibited among men to-day, but that he was perfectly endowed, perfectly adapted to a complete performance of all the purposes of his being, of all the requirements of his day and generation.

It is but a reasonable proposition that the first man had, of necessity, to be put upon trial for a continuance of his high estate, his perfect life, his high endowments, his dominion of earth, his rulership over all the living forms about him; reasonable, also, that his Author, God, would be equal to the emergency of failure resulting from that trial—at the same time it is but reasonable to believe that that first man, who failed when the world of mankind were in his loins, will, after his awakening, have another trial with full opportunity under more favorable conditions, and that he will be abundantly qualified to profit by his former experience of nine hundred and thirty years in the pit of death.

It is in harmony with all the various doctrines of all the various books of the Bible that no member of the family of Adam will attain to perfection of life, either upon the spiritual or upon the human plane, without trial in judgment. Failure to recognize the truth that Christians only were on trial has led the nominal church into many confusing errors, while her failure to differentiate as between everlasting life, though liable to death, and that condition of life termed immortality—inherent life—is an unmistakable evidence that she is not shedding forth the true light of the knowledge of God in His complete and perfect plan for the development and salvation of mankind.

Although it may seem to be contradictory to the foregoing statement, yet it is profoundly true that the nominal church, through sectarianism, is now and has been during the past, grandly, though blindly, filling up all the divine purposes of her being, while rapidly approaching the end of her career. Orthodox theology, so-called, teaches nothing, knows nothing, in respect to human perfection, having lost sight of the "faith once delivered to the saints." The foundation of that faith includes the sure knowledge of the coming "earthly phase of the kingdom of God" for the special purpose of blessing unto perfection "all the families of the earth," by and through the right hand of power from on high.

This teaching is in harmony with the voice of Him who speaks from heaven through His Word, in harmony with the teaching of the "Church of the Living God," "the Church of the First Born," "the pillar and ground of truth," not man made, nor man ruled. It is the teaching of them of "no sect in religion," of whom the most widely-known living exponent of divine Truth is Chas. T. Russell, Allegheny, Pa.

Why Do Medical Incomes Decline?

BY H. SPEIER, M. D.,
Rochester, Minn.

A friend, a leading practitioner in a city of seventy-five thousand inhabitants, speaking, in a private letter, of an evident decline of medical incomes in that city, finds a reason in the fact that so many of the best families, who used to supply an appreciable portion of the annual income, have been lost, having become Christian Scientists. This is, undoubtedly, a correct idea, and will be subscribed to by many physicians in all parts of the country, for everywhere has a certain shrinkage in incomes become apparent. But why is it that so many of the most intelligent people among the laity turn from rational medicine and take up irrational facts? The medical profession itself is largely to blame for it.

For one thing, we have gone mad on surgery, and are going madder and madder every year. The great technical advances growing out of asepticism, the many cures accomplished by modern surgery, the great financial returns obtained, and enviable reputations built up by surgeons in all parts of the world—all have combined to raise surgery to the highest pedestal and make it appear as the crowning glory of the healing art.

No one who has not, as the writer has had the opportunity of doing during the last two years, traveled over considerable territory, visited physicians and studied the conditions of medical life and practice, can realize to what extent the profession worships surgery and the surgeon. Every young man, fit or unfit, aspires to be a surgeon, and can see in his patients only surgical "cases." You must have, at least, a dozen appendices, a bottle full of gall-stones, and a few extirpated uteri to show before you can ask to be heard, just as the young Indian warrior could have no voice in the councils of his tribe until he had a number of scalps at his girdle. Ask what kind of a man is Dr. J., in the neighboring town, and most likely you will be told, "Oh, he does not amount to much, he does no surgery at all."

Once a physician was valued by his confreres in proportion to his general wisdom and knowledge of therapeutics; now it is boldness and mere manual skill which give him high standing. The spirit has been imbibed by a large part of the general public; but many, and those the most intelligent, shrink from the blind worship of surgery and its dangers, and turn to other, milder methods of healing, such as osteopathy, Christian Science, etc. About six million people have thus ceased to contribute to the support of the medical profession.

Close kin to this over-valuation of surgery is the contempt of therapeutics which the present medical generation affects. Not a mere affectation, either; it is inbred through defective college training. The charge that they neglect the teaching of therapeutics and fail to give students a proper knowledge of drugs and their uses, has been brought against our medical colleges so frequently, and from so many sides, that it is needless to dwell on it now. The result is painfully apparent in daily practice. Hear these younger men discourse learnedly to their patients on the germs infecting them, minute pathological changes, toxins, the opsonic index, etc. But when it comes to the question of treatment they dismiss it with an off-hand, "Oh, you may take a dose or two of quinine, or a little calomel," or this, that, or the other, conveying by their manner the impression that treatment is of no consequence or interest whatever. But to every sick person it is of cardinal importance. His physician's indifference drives him to where, at least, a show is being made of caring for him to the osteopath, Christian Scientist, or others. This is one of the blessings brought to us by the therapeutic nihilism which dominates medical education to-day, and the chief apostle of which is Professor Osler.

Diagnosis is the thing, anybody can apply the treatment, is the frequently heard confession of faith of the followers of Osler's teaching. Diagnosis, to them, is chiefly the laboratory variety. The microscope, blood count, bacteriological test, all the new instruments of precision are very valuable additional helps, but the modern American physician puts too much dependence on them. He has come to look upon them as infallible, placing the pathologist and laboratory worker on an exalted plane, at the expense of the other diagnostic methods of percussion, auscultation, and purely clinical bedside observation. Their place can be taken by nothing else. Laboratory diagnosis is tending towards mechanical, machine-like accuracy. But, as yet, it retains too many elements of uncertainty and possibilities of error. The best men are recognizing this. Dr. Richard Cabot, of Boston, has, in some widely-discussed papers, pointed out the fallacies of the clinical examination of urine. James B. Herrick, of Chicago, in the oration on medicine before the last meeting of the A. M. A., calls attention to, and warns against over-reliance on laboratory diagnosis. Strimpell and Van Noorden, in Germany, in recent lectures, emphasize the need of more thorough teaching and application of the methods of physical examination, and a

professor of the University of Berlin, lately returned from a visit to our country, criticises us for making a fetish of laboratory diagnosis. This super-scientific craze leaves the young physician less ready to meet the demands of ordinary, everyday practice, and helps to drive his patients away.

The encroachment on medical incomes by badly-managed medical charities, has been and still is a favorite topic of discussion in medical journals and societies. It is a serious evil. No relief has, as yet, been afforded, and none need be looked for, until social conditions in general have been remodeled.

Another cause, equally well understood and, apparently, equally hopeless, is the unnecessarily large number of medical colleges and never-ceasing over-supply of physicians they send out annually. It was thought that raising the standard of admission to medical schools, lengthening the course of study, increasing materially the cost of it, and requiring additional State examinations, would force out superfluous schools and limit the number of students, but no such result has followed. While the cake is getting smaller, the number of partakers is not lessening. Who can suggest the remedy?

Social advances of recent times are chiefly in the field of sanitary improvements, such as the better housing of the poor, furnishing wholesome milk for infants, purifying the water supply of cities, organizing the fight against tuberculosis; in short, removing the cause of disease. All these movements have been originated by physicians, and carried onward by them, often against bitter opposition from those most benefited, giving freely to the public from their special knowledge, and creating an entirely new science, that of preventive medicine. The medical profession occupies, in this respect, an unique and anomalous position. No other calling shows such an unselfish, genuinely altruistic spirit. For this work, upon which we unite our best efforts, the prevention of disease, must make, in the end, the present-day physician altogether unnecessary. We are cheerfully digging our own graves.

A number of factors contribute to reduce the average income of the average physician, and make his existence more and more precarious. Some are avoidable and remediable, being founded on misconceptions; others are not, being manifestations of universal social tendencies.

[Written for the MEDICAL BRIEF.]

Entero-Colitis—Enteritis.

BY EDWARD C. ROTHROCK, M. D.,
Ex-Surgeon of the Confederacy.
Palestine, Texas.

Modern writers have divided the alimentary canal below the stomach into three sections in relation to inflammation and designated that affection as it occurs in those different sections by the following terms: Duodenitis, for inflammation of the duodenum; enteritis, for inflammation of the jejunum and ileum; colitis, or dysentery, for inflammation of the large intestines. The first of these, the duodenum, I shall not discuss separately, as the duodenum is seldom diseased alone, and if it is, no indications of treatment differ from that pertaining to the affections where the stomach and intestines are involved. Therefore we shall apply the term enteritis to inflammation of any portion of the mucous membrane of the small intestines. The inflammation of which this paper will notice is most frequently located in the ileum, and by some writers denominated enteritis, by others ileo-colitis, entero-colitis, etc. As the colon is apt to be more or less involved when the ileum is inflamed any length of time, extending by continuous sympathy to other portions of the mucous surface of the tube, hence inflammation of the small intestines, and especially of the ileum, is most always in protracted cases. extended to the colon, with the diagnostic symptoms. The two extremities of the small intestines, the duodenum and ileum, are more liable to inflammation than the jejunum, the duodenum is in more direct association with the stomach and liver, and more liable to be sympathetically affected when they are diseased, the ileum being in a position which will account for its liability

to irritation and inflammation. The diminished caliber of the ileum, at its lower part, and especially at its entrance into the cecum through the ileo-cecal valve, is calculated to retard the process of the intestinal contents, holding them longer in contact with the mucous surface, and thus subject it more to the action of an irritating substance that may be present than in the upper portion of the intestinal tube.

Inflammation of the mucous membrane of the small intestines usually commences with uneasiness, often obscure in the commencement, but gradually increasing, until pains of a griping character, more or less constant, is felt about the center of the abdomen. The most severe pain will be felt in paroxysm, with sensation of distress between them. The griping is so severe in children sometimes as to cause convulsions, and in adults the suffering is often very great. In mild cases there is but little pain; again, the pain, instead of commencing gradually, is violent at first; the pain is felt about the center of the abdomen, or umbilical region; depending in some measure, on the locality of the attack. If it is in the duodenum, or first portion of the jejenum, the pain will be felt higher, more deep-seated; perhaps referred to the back; whereas, if the ileum is the part affected, especially the lower portion of it, the pain will be in the hypogastric, extending also into the right iliac region, and frequently pronounced by some over-wise surgeons, who wish to carve, "appendicitis." There is more or less tenderness under pressure, corresponding in measure to amount of pain experienced, and this serves better than any other in fixing the location of the inflammatory lesion. Diarrhea is a common symptom of enteritis, and rarely absent, unless in cases where the disease is caused by obstruction. If this symptom has not appeared, it may at any time be easily produced by even mild purgatives, which should be used with great care and judgment. The evacuations are peculiar, and their character should receive attention. If the disease is confined to the small intestines, they will be watery, and of a dirty yellow color, containing but little mucus, but if the colon is involved, there will be more mucus, and often mixed with blood in the discharges; an extension of inflammation into the colon will also be marked by tenesmus, and more severe bearing-down pain, or dysentery, in addition to the griping, twisting and cutting pains of enteritis. At first the stools will be fecal, mixed with matter, but when it passes off they will assume the sero-mucous type. In some cases the stools are decidedly bilious during the progress of the disease, indicating that the liver has taken on a sympathetic action, and is more apt to be the case where the duodenum is involved in the inflammation, or becomes highly irritated. Commonly there is a deficiency of bile in the evacuations. When bile is present it is apt to be charged, and impart a greenish color to the dejections. It is, therefore, important to give special attention to the character of the evacuations, as much is to be learned respecting the real condition of the patient, the amount of bile, its character and other peculiarities of the stools in disease of the bowels, and will serve as a basis of a true diagnosis. The bowels are not usually bloated or distended with gas, to the extent of producing tympanitic symptoms, but occasionally, and especially in children, and in protracted cases of adults, this symptom is present; generally at first the abdomen is in a collapsed, or sunken condition. The bile symptoms are present in all cases of enteritis, and it is common to find the fever exhibiting the remitting type, assuming the initiatory symptoms of "bilious fever," presenting, more or less, marked remissions. This complication of enteritis, with periodic fever, is especially frequent in malarial locations. If such is the condition, there should be no hesitancy as to the course to pursue. Arrest the periodic fever before anything else, with antiperiodics, and the inflammation will yield at once. Diarrhea, depending upon the mere debility of the bowels, local irritation, or atony of the intestines, in which there is no fever, or very little, is not included in this paper. The febrile symptoms in enteritis are not as intense as in many other cases of inflammatory disease. The pulse is some-

what accelerated, but open and full; very unlike the rapid, quick pulse characteristic of peritoneal inflammation. The skin will be more or less hot and dry, the tongue moist and slightly coated, and the urine scanty and highly colored. The febrile symptoms sometimes precede those of local disease, in which cases they are usually more prominent, as the reaction is apt to be much greater. As a general thing the character of the disease is mild, and prognosis favorable, where there is little pain, diarrhea, or fever, and it usually terminates in health in a short time without, or with very little treatment—rest, diet and good nursing. Where the symptoms are severe, it will generally yield readily to simple and appropriate treatment. Whether the inflammation is primary attack, or secondary one, resulting from fever, and some cases of the latter description, especially under improper management in the beginning, assume a grave, untoward condition. Where this is the case, and, indeed, where from any cause the disease assumes an unfavorable aspect, the symptoms become aggravated, the pain increases as the inflammation extends; the discharges become more offensive; the colon becomes involved, with all the symptoms of dysentery, or the stomach becomes implicated, as manifested by nausea, vomiting, pain and tenderness in the epigastrium; the skin and eyes become yellow, indicating involvement of the liver, or closure of the bile-ducts; the tongue becomes red and dry; the brain and nervous system are affected; delirium, perhaps, appears; the pulse is frequent and feeble, and the patient gradually sinks from exhaustion, or suddenly dies, owing, it may be, to perforation of the intestines, or to mortification. If the case does not prove fatal, it may run into the chronic form of inflammation, or the patient may recover after a tedious and prudently-managed convalescence. The causes of enteritis are numerous and various. A very common cause is exposure to cold; "taking cold," getting wet in a shower, the sudden vicissitude of temperature which destroys the equilibrium of the system, and develops disease at the weak point; another cause is the sudden recession of eruptions from the surface. This is especially frequent with children that have any of the exanthematous diseases, or the eruption commonly called "rash"—which is, itself, dependent on gastric and intestinal derangement. It is said to result from metastasis of gout and rheumatism, which is not at all improbable. It may result, also, from the suppression of accustomed discharges. Another frequent cause of enteric diseases is the presence of irritating substances, indigestible articles of food, which, having resisted the action of the stomach, have passed in a crude or slightly altered form, into the small intestines, where they irritate the mucous membrane until inflammation is developed. Acid or morbid secretions, especially vitiated bile, are doubtless often the cause of inflammation of the bowels. Accumulation and induration of the ordinary contents may occur from inactivity of the bowels and produce inflammation. Relaxation, resulting in intussusception, or imagination and strangulation from hernia, etc., are also causes of inflammation of the small intestines. Enteritis is a frequent attendant on other affections, general or local, as fevers, whether malarial or contagious; consumption, gastritis, hepatitis, etc. The specific tinctures are used in all cases, and dose is for adults in this paper. Indications for treatment is rest, diet and good nursing. If fever is high, spec. tinct. aconite one drop every half-hour, or every hour. Use it frequently thus: spec. tinct. aconite twenty drops, aqua four ounces; teaspoonful, as above, until fever is reduced, then every two or three hours. Aconite will antagonize the fever process, and is a valuable drug in fever produced by inflammation. Its power over the circulation, respiration and transpiration is marvelous, when rightly used, in small doses. It is prompt, and sure to reduce fever, relieve pain. In high fever, a resisting pulse, hot, dry skin, frequent discharges from the bowels, we give this frequently with success: Spec. tinct. aconite one drop, gelsemium eight to ten drops, every two or three hours, or every hour until the effects of the aconite are felt upon the frequency of the pulse, and ef-

fect of the gelsemium are seen upon the eyes, then give it at longer intervals. If the case has not been seen at first, and the symptoms are grave, violent colic-like pains, great tenesmus, and the discharges frequent, offensive, ill-smelling, with little mucus, antiseptics are used. Baptisia three to five drops every three hours, until the stools cease to be offensive. If the colon is implicated, manifested by passage of large amount of blood—dysentery—hamamelis tinc., in doses of ten drops, should be given every hour or two until the hemorrhage ceases. Geranii—crane's bill—is also a nice remedy, and has a pleasant taste, therefore suitable for children. If there is nausea and vomiting, with or without bloody evacuations, and tenesmus, small doses of ipecac tinc., and podophyllum, two drops, each every hour, or half-hour, will check it. We have frequently used arsenite of copper 1/100 grain, water four ounces; a teaspoonful every twenty or thirty minutes, and it acts like a charm. If the upper intestines are bound up, a mild aperient, as cream of tartar, epsom salts, or rochelle salts, are used in small doses. The phosphate of sodium is efficient. Aromat. syrup rhubarb is a fine remedy, particularly for children; dose for which is ten to thirty drops; adults teaspoonful; small doses should be given once or thrice a day, as indicated, and should be used every day or two to keep up action of the upper bowels, which will materially aid in the cure. Aconite and bryonia-alba will reduce fever, tenesmus and pain. So will gelsemium. If there is evidence of periodicity in the fever, then quinine and other appropriate remedies must be used, as these malarial properties that frequently maintain and perpetuate the disease must be aborted at once, then the disease is easy to control. Where the bowels are distended with gas—tympanitic—dioscorea—bile, tinct. twenty-five drops, mint water four ounces, teaspoonful every one or two hours, will relieve. Warm poultice of flaxseed meal, or corn meal spread thin, so as not to be heavy, will give comfort and great relief. Turpentine, sprinkled here and there on the poultice, will enhance their effect greatly. Diet should be light and easy to digest; liquid or semi-liquid food should be used; fresh milk which contains in itself all that is required for the wants of the organism. There is in it fat, nitrogenized matter, sugar and salts. It is palatable when fresh, and relished by most persons. In conditions of great debility, and in early convalescence, milk is the food par excellence; it supplies nutriment, both plastic and respiratory. Milk may be thickened with corn flour, then an egg beaten up with it; sugar added. This is excellent in gastric-catarrh. When indicated, alcohol may be added to milk—a punch, as the famous "rum and milk" preparations. Buttermilk is an agreeable beverage to most persons. The milk—sugar has been broken up into lactic acid, soft-boiled eggs, soups, light-bread and fresh butter; light-bread milk toast, as a change. Beef tea, with sago, or arrowroot, is a good diet. Biscuit powder, or fine bread crumbs, and a little fresh butter, with pepper and salt to taste, or fine bread crumbs added to beef tea, is nutritious. A pleasant diet is rice water, the well-known "cungee-pawnee," boiled rice and milk, beef and chicken soups, mutton broth, are suitable in most cases. Tea and coffee may often be used to advantage. Coffee is a useful stimulant in affections of children. Wine whey is of great use, and very nourishing.

The administration of stimulants, alcoholic or nitrogenized, should always be in proportion to the reserve fund of the system, and the urgency of the emergency.

[Written for the MEDICAL BRIEF.]

Toxins and Antitoxins.

BY G. A. PERSSON, M. D.,
Mt. Clemens, Mich.

The kind invitation to contribute a paper for your esteemed journal was an unexpected honor, and I take great pleasure in complying with your request.

The subject which to-day is occupying the mind of the medical men, perhaps, more than any other subject, in medicine, is that of Toxins and Antitoxins.

Recognizing the fact that germs do bear a causal relation to some diseases, the question arises, How do these organisms produce disease? In what way does the

Kleb's-Löeffler's bacillus, for instance, induce the symptoms of diphtheria and death? Many answers to this question have been offered. Some of the most important ones are as follows:

Bollinger has suggested that it was due to the deoxidation of the blood by the micro-organisms, and another theory would have us believe that the germs consumed the proteids of the body, and thus deprived it of sustenance. The proteids are known to be necessary for the building up of cells, and it is also known that germs feed on proteids. Still another theory, which has been offered, is that the bacteria destroys the blood corpuscles, or lead to their rapid disintegration.

Seeing the vital deficiencies of the above theories, and being impressed by the results obtained by the chemic study of putrefaction, bacteriologists have been led to inquire into the possibility of the symptoms of infectious diseases being due to chemic poisons. In investigating this theory three possibilities suggest themselves.

1. The micro-organisms themselves may be poisonous, or the poison may be an integral part of them. Nelson advocated this theory at one time, thus accounting for the appearance and increase in violence of the symptoms as the germs increased in number. In order for the conditions of this theory to be fulfilled, the germs must be present in the blood before the symptoms appear, but we find, in many of the infectious diseases that the micro-organisms which induce this disease are not found in the blood at any time. It has also been proven, experimentally, by Hoffa, and others, that injection of a large quantity of anthrax bacilli, directly into the blood, is followed by no symptoms for from twenty-four to seventy-four hours; while, if this theory was true, we would naturally conclude that symptoms of the disease would follow immediately, and death would be speedy.

2. The micro-organisms may be intimately associated with, or may produce a soluble ferment, which, by its action on the body, produces the symptoms of the disease, and death. This theory formerly had many ardent supporters, among whom may be mentioned the eminent scientist, DeBary. But Pasteur proved the theory false when he filtered anthrax blood through earthen cylinders, innoculated animals with the filtrate, and failed to produce any effect.

3. Poisons may be produced by the cellular activity of the bacteria, much in the same way as morphine is formed in the poppy. This theory finds, in the first place, strong support in the well-known fact that many of the putrefactive germs produce highly-poisonous bodies; and, in the second place, the formation of the chemic poison will account for the appearance of the symptoms of the disease when the living micro-organisms never find their way into the blood.

The correctness of this theory has been tested by a large number of investigators, and with the result that its truth has been firmly established.

An infectious disease arises when a specific, pathogenic micro-organism, having gained admittance to the body and having found the conditions favorable, grows and multiplies, and in so doing elaborates a chemic poison called toxin, which induces the characteristic effects.

What are these effects? They produce the development of clinical symptoms which we have learned to arrange into groups, and from the peculiar arrangement of these symptoms we diagnose the disease, and build our hypothetical prognosis.

The cardinal symptom in all acute infectious diseases is the temperature, and no other one symptom is watched with such close attention by the attending physician. It may, for this reason, not come amiss if we here briefly consider what relation the toxins bear to the temperature.

Pyrotoxin is found in all kinds of bacteria, both pathogenic and nonpathogenic, and there seems to be no relation between the quantity of this substance contained in the bacterial cell and the pathogenic action of the living germ. Pyrotoxin is a constituent of the bacterial cell proper, and not a split product formed by analytic action of the bacterium on constituent of medium, in which it grows. Pyrotoxin, when prepared from a fresh culture, is a

grayish-white substance that appears under the microscope in form of fine granules. It is very hydroscopic and decomposes after a short exposure to the air. It is soluble in water of neutral, feebly alkaline to feebly acid reaction. Pyrotoxin causes the elevation of temperature, and induces the complex of symptoms included under the term of fever.

The special toxins formed by the specific germs, which now are regarded to be the cause of many of our prevalent diseases, have been extracted from these micro-organisms, but space does not here permit me to give even an outline of this instructive and interesting subject. Fraenkel has been successful in extracting from the Kleb's-Löffler bacillus a poisonous albumose, of which 0.15 gram was sufficient to kill a guinea pig within eight minutes. Pfeiffer finds that the toxin in typhoid fever is contained in the bacterial cell. He has, from culture of the Eberth bacillus, extracted a poisonous proteid. With this poison animals can be rendered immune to the Eberth bacillus, but not the bacillus colicommunis. This typhoid antitoxin is also present in the blood in persons convalescing from typhoid fever.

When it became known that some of the specific pathogenic germs elaborated poisonous substances which were the direct cause of many diseases, the energy of many honest toilers in the laboratories of science was bent upon the discovery of some antidote for these toxins.

The brilliant success of Jenner with vaccination against small-pox, and the great achievements of Pasteur in hydrophobia, have given ground for the hope that like results may be secured in protecting man from other diseases.

To establish immunity against such deadly infectious diseases as tetanus, typhoid fever, pneumonia, diphtheria, cholera and tuberculosis, or to abort an attack of these diseases by the administration of suitable antitoxins, are complexing problems with which the student of scientific medicine does to-day busy himself.

In order to properly understand the action of antitoxins, we will consider, for a minute, the subject of immunity.

We are all well familiar with the Metchnikoff's phagocyte theory. The term "phagocyte" implies any cell which is capable of incorporating bacteria, and destroying them by a process of digestion. Bullock states that thousands of facts points to the conclusion that our leucocytic-forming tissues are our great defensive organs against parasitic invasion, but that the mystery is how the microbes are destroyed.

The view that the serum was endowed with bactericidal powers has been ably defended by Pfeiffer, von Foder, and others. Their labor led to the doctrine of which the late Professor Hans Buchner is the main exponent. Both he and Hankin isolated substances which they termed alexins, and to these bodies they ascribed the power to confer immunity. They were also thought, by Buchner, to be derived from the leucocytes, the oxyphil, and kindred cells. Gruber was led by a large number of experiments to conclude that the actual destruction of bacteria, in all animals, whether actively or passively immunized, was due to the Buchner's alexins, and that the alexins were general protective substances, entirely without specific action. According to Gruber, the bacterial cell was first made adhesive by the blood's agglutinans, and thus made vulnerable to the destructive action of the alexins.

In 1897 Ehrlich advanced a theory, called the Ehrlich's side-chain theory, which aims to harmonize the results so far reached in the study of natural and artificial immunity, and particularly the formation and mode of action of the immunizing constituents of the blood serum. Reduced to its simplest expression, Ehrlich's theory is not, on the whole, a complex one, and it is based on recognized biologic and chemical principles.

The body, being composed of colonies of cells, which differ from one another in their functional attributes, nerve-cells, muscle-cells, gland-cells, etc., we speak of the specific action of drugs. Thus, the cerebro-spinal motor cells have affinity for strychnine, the cardiac muscle cells for digitalis, the sweat and salivary, jaborandi, etc. Now toxins differ in no way from remedies in this particular; they are specific, owing to their cellular affinities, toxin being also taken up by specific

cells. This specific action of toxins represents the foundation upon which Ehrlich's theory is poised.

The theory itself is based upon the mechanism of cell nutrition in its relation to its mode of production of specific antitoxins, bactericidal and antitoxic sera.

The complexity of cellular protoplasm is well known to biologists. Ehrlich assumes that each cell contains an active central nucleus, and a group of molecules or side chains. The outside, or extranuclear group, constitute the cardinal feature of the entire scheme, since each of them has for its function to receive (hence the term receptor) the molecules of foodstuff, which perpetuate the cell existence. These molecules Ehrlich calls heptophores, owing to their identity as extrinsic carriers. A cell nutrition is thus carried on through the affinity its receptors, or side chains, have for its heptophores. Unfortunately, the receptors do not combine with these nutrient substances only; their affinity extends to substances which are, in measure, their chemical analogues, and which may include harmful bodies. Thus a poison, a toxin, or a venom, may contain the same elements, and the same number of them as a nutrient molecule, or heptophore, the only difference between the latter and the pathogenic molecule being a different arrangement of their respective atoms (isorism). The formula of turpentine, for instance, is C_{10} H_{16}, while that of oil of lemons is also C_{10} H_{16}, and yet their properties are quite dissimilar. The same may be said of ethyl formate, methyl acetate and propreonic acid, all of which have a molecular weight of seventy-four, and the same formula, C_3 H_6 O_2. This makes it possible for a cell to take up (combine with its nutrient heptophore) any number of isomeric non-nutritious bodies, and when one of these happens to be toxic, thus forming what Ehrlich calls a toxophore, the latter combines with the cell, and, if sufficiently active, qualitatively and quantitatively, may act destructively upon it.

If the toxin is not sufficiently active to destroy the cell or inhibit its functions, the latter seeks not only to rid itself of the poison, but also to protect itself against further aggression from this poison and its isomers.

Intoxication being due to toxins, for instance, the toxin group of hepthophoric molecule attaches itself to the receptors, and then reacts actively upon the cell proper. The receptors themselves being destroyed, the cell not only replaces them by reproduction, but the process is so active that many more receptors are created than are required by the cell itself, and they accumulate in the blood and lymph. These surplus receptors preserve their affinity for their specific heptophores, and, therefore, for any isomeric toxin that may combine with it. The receptors thus become the cell's protectors, since they capture and hold, as it were, the toxin before it can at all reach the cell proper, thus immunizing the latter against the poison.

Diphtheria toxin, for instance, by exciting the cells for which it has specific affinity, causes these cells to liberate receptors in large quantities; these, by at once combining with the rest of the toxin in the blood stream, curtails its morbid effect. Antitoxin, therefore, owes its curative properties to the receptors it contains.

Less this paper be burdensome by its length, I will close by recalling to your memory the commercial preparation of antitoxins.

It is, of course, common knowledge that an antitoxin is the blood serum of an animal after the latter has been rendered highly immune by repeated injection of appropriate toxin.

The horse is chosen for immunization because of its marked ability to yield antitoxins, because of its size withstanding much loss of blood, and because of the readiness with which it submits to manipulation.

Manufacturing plants which produce antitoxins and other antiserums on a large scale, have splendidly-equipped stables which are kept in a maximum hygienic condition, and from which rats are particularly vigorously excluded. The horses are carefully groomed and fed, and given such exercise as will keep them in healthy condition.

The toxins in solution are injected subcutaneously. Grave and even fatal results may follow the first injection if the toxins have been given in too large doses, or in too concentrated solution.

It is of great importance to establish, first, what the Germans call grundimmunitat, which means primary immunity in the animal itself, so that the immunization may then be pushed *vigorously*, until the blood contains antitoxins of high concentration. For this purpose it has been found necessary to weaken the first toxins injected. This may be done by heating the toxin for about an hour at 70° F. Gradually, the virulence and the amount of antitoxin may be increased until, finally, the full virulent toxin is given in large doses. The increase in dosage must be gradual. Eventually, as much as a liter or more of the diphtheria toxin can be tolerated.

Following each injection a reaction occurs. With diphtheria the local swelling may be great, and sloughing may occur. Following an injection of tetanus toxin, the tetanic symptoms may appear. In either case, there is some loss of weight, and often fever. The next injection is not given till the fever has subsided, and the original weight is restored. This interval is, usually, from eight to fourteen days.

From two to three (and sometimes more) months of such treatment are usually sufficient to produce antitoxin of high concentration. At the end of this time blood is drawn from the jugular vein by means of a large trocar, to which a rubber tube is attached. The tube leads to a tall glass cylinder, holding from one to two liters, and into this the blood is allowed to flow. Six liters may be safely drawn from a horse of average size. The most rigid asepsis is, of course, observed in collecting the blood. The glass cylinders, appropriately covered to prevent contamination, are then set aside in a cool and dark place, and, after the serum has separated from the clot, samples are taken to be tested for their antitoxic value.

The necessity of standardizing antitoxin, so that the dosage may be controlled accurately, is self-evident. To meet this need the antitoxin unit, familiar in practice, was devised. It was necessary to decide, first, on some arbitrary unit of measure. The only way there is to estimate the value of antitoxin is its ability to neutralize its corresponding toxin. Consequently, to standardize antitoxin it was necessary to first devise some unit of measure for the toxin itself. For this purpose the Behring's toxin unit is generally used. A diphtheria toxin was designated normal when it was such strength that 0.01 cubic centimeter would kill a guinea pig weighing two hundred and fifty grams, in four days.

Measuring the antitoxin on the basis of the toxin unit, it has been determined to consider an antitoxin of normal strength when 0.1 cubic centimeter will protect a guinea pig of two hundred and fifty grams against a one hundred fatal dose of diphtheria toxin. This value is called antitoxin unit.

The indications for the use of antitoxins, and the technic for the administration, together with the correct dose in each case, are facts which every practitioner should be perfect masters of.

I will not detain you with the details thereof, because I know you are all familiar with them.

If I have, in some way, been successful in presenting to you a few of the many interesting facts which go to make up this important subject, the purpose of this paper has been accomplished.

[Written for the MEDICAL BRIEF.]

That Old, Too-Well-Trod, Beaten Road.

BY E. B. SILVERS, M. D.,
Rahway, N. J.

Our profession is too much given to keep, like a locomotive, on the same old track. If some physician or surgeon of Vienna, Paris, Germany, or some other foreign country of note, sends forth some new theory, the prestige of their name often attracts enough to insure a trial, too often futile. But if an intelligent country practitioner, of careful observation, recommends, after careful trial, some new theory tried to the extent of many successful issues, it falls flat, as the

source is not appreciated; yet the most successful results in the arts and mechanics have risen from such obscure sources.

The writer, many years ago, tried successfully sulphite of calcium to saturation as a prophylactic, as well as a modifier of measles when established. The experiment was well tested among adults, where this disease is most virulent. Well-authenticated cases were proven of its efficacy and also of its modifying effects in small-pox, preventing pitting, externally using an ointment of one drachm calamine, one ounce basilicon ointment, four drops of carbolic (pure) acid. But it comes from an obscure country doctor, and, consequently, attracted no special attention, and my belief is that in all eruptive diseases this is a reliable remedial agent. Next, that salycilate of soda, in five-grain doses, four times a day, will dissolve gall-stones and prevent hepatic colic. I go further and state that this same agent will dissolve some forms of stones in kidney and bladder, but who will try them, when the source of the discovery is traced to non-celebrated sources? In a practice of fifty-four years, of careful observation of means to a successful ending, I claim that all mature physicians must have struck some valuable curative means of service to the profession. I do not suffer the diffidence which controls so many.

[Written for the MEDICAL BRIEF.]

My Front Door Key.

BY B. E. DAWSON, M. D.,
Belton, Mo.

One morning, recently, when I arrived at my office door, I had to search through a small bunch of keys to find the one I needed, on account of its diminutive size. This reminded me, by contrast, of the key to my father's factory door, in use more than forty years ago. The key to my office door weighs one drachm, and is less than two inches in length. The key of my youthful days was a large, complicated, club-like piece of iron, that weighed three or four ounces. I remember that each business house in the village had a key similar in size.

In those days we thought protection was in proportion to the size of the key, but we have learned better. My office door is heavier, the bolt larger, and the lock more difficult to pick, than were those of my father's.

This line of thought was followed into the various fields of the then and now, until I was overwhelmed and charmed with the beauty, the utility and the potency of the little key to the large front door. Some of us are slow to learn, but many are beginning to use the little key to accomplish great things in the different departments of life. Like Elijah, we must learn that God's power was not in the tempest, nor the earthquake, nor the sheets of fire, but in the still, small voice. In olden times, God thundered from Sinai, "Thou shalt," and "Thou shalt not;" but now he says, in the still voice of the Gospel, "Blessed are they that do his commandments."

The bells, springs and cords have given place to the delicate push button, so that with the tip of the finger we can arouse the occupants of a large building. The President, in Washington, may turn the little switch-key, and start the wheels of ponderous machinery in a distant city. The little child's delicate finger may touch a key and blow up Hell Gate.

When we enter the realm of our profession we also observe the efficiency of the small key. Blacksmith tools are not used to repair a gold watch. The machinery of the human body is far more delicate and nicely poised than any chronometer; its repair usually requires small tools and delicate touch, or irreparable damage may result.

My first observance of the science (?) of medicine and surgery was the large dose of calomel, and the big clumsy turn-key, or twister, for extracting teeth. It seemed to me, if I stubbed my toe, or had the stomachache, the headache, or hives, my father gave me nearly a teaspoonful of calomel. The way he got teeth out with his elevators and turn-keys, and bled patients, was a sight long to be remembered, if one could bear to look to the completion of the fearful ordeal.

When we look back on memory's page at the large, nauseating doses of pow-

dered Peruvian bark, rhubarb, iron, calomel, etc., some of us, with a retching, resisting or puking personal experience, we are favorably impressed with the more pleasant and potent power of the little key. When we are shown (only as a relic, I trust) the dental, surgical and obstetrical instruments used a few decades back, we are at once convinced of the superior utility of the smaller instruments of the present day.

I believe in the platform, "The smallest possible quantity of the best obtainable means to produce a desired therapeutic result," to be safe and efficient. We get better results, more safely and pleasantly, with one-tenth-grain doses of calomel, repeated to effect, than did our fathers with heroic doses. We do neater and more efficient work with the small instruments than did our predecessors with what they used.

Another observation about my small key: It must fit the lock accurately. A key with very slight variations, in shape or size, will not answer. So it is with our therapeutic means; they must meet the indications. Ipecac will stop vomiting when indicated by persistent irritation of the mucous membranes, pale, relaxed, and white coated. Otherwise it will fail—is the wrong key. If the tongue is flabby, broad and indented by the teeth, small doses of nux vomica will be the key to throw this bolt, and securely close the door of egress. And so through the entire list of pathological conditions; we must study closely each symptom, to be enabled to select the indicated remedy.

Next in importance to results, in the demand of the age, is the pleasant and agreeable manner of obtaining results. I have seen (and *experienced*) cases where the patient was prostrated in bed for several days as a result of vigorous medication, that, with proper treatment, need not have been in bed a single day.

The physician should be preëminently a close observer. He should enter the sick room, or approach a patient, with all of his five senses alert, and each one bristling with interrogation points. Otherwise, he may not be able to select the proper little key, so greatly needed at that time.

[Written for the MEDICAL BRIEF.]

Lithium Benzoate.

BY J. A. BURNETT, M. D.,
Auburn, Ark.

While lithium benzoate does not have a very wide range of action, it is a remedy that fills some places with very good success. In my opinion, the most valuable effect of it is in what is commonly called "burning urine," that is, there is a burning sensation while urinating, with no specific affection. I have treated many cases of "burning urine," and was never successful until I learned to use this remedy.

In all cases of "burning urine" I test the urine, and if it is hyperacid I use lithium benzoate, five grains, three times a day. If I find it alkaline I use ammonium benzoate, same way. In most all cases it will be found hyperacid. Such a large per cent is hyperacid that I often prescribe the remedy without testing the urine.

I cured a man, about fifty years old, of "burning urine," with lithium benzoate, that had tried every doctor in his reach without being benefited in the least. I cured a married lady, aged eighteen, of the same complaint, that had been in such condition ever since she could remember. Upon examination I found her urethra irritated. The trouble was so bad that she could scarcely walk or stand at times.

I relieved a four-year-old girl that had been bothered with "burning urine" nearly all her life. At times was so bad that she could hardly stand it. I found the urethra irritated in this case, which proves that the remedy influences the urethra.

These cases all had hyperacid urine.

Most all of my cases of "burning urine" have been women and girl children, which is worthy of mention.

Lithium benzoate is useful in rheumatism, and is considered an intestinal antiseptic. It is beneficial in acute laryngitis when there is hoarseness. It is an expectorant, and can be used in some cases of chronic bronchitis. The dose

ranges from one to thirty grains. The average dose given by the new United States Pharmacopeia is fifteen grains, but this is too much. I consider five grains an average dose.

[Written for the MEDICAL BRIEF.]

The Prognosis and Treatment of Burns.

BY MILTON P. CREEL, M. D.,

Surgeon L. & N. Railway: Member American Medical Association; Ex-Vice President Kentucky State Medical Association; Referee for Muhlenberg County for the Kentucky State Board of Health; Secretary Muhlenberg County Board of Health; Member United States Board Pension Examiners; Surgeon I. C. R. R., Etc.
Central City, Ky.

There is, I am persuaded, much misapprehension in the minds of a great many physicians and surgeons regarding the prognosis of burns. This is due to the fact that the text-books on surgery are defective on this point. These works, as a rule, are full and accurate on all other facts pertaining to burns, but in many great surgical treatises no mention is made of the prognosis. This, to my mind, is a serious omission, and to it I can attribute some lamentable errors of prognosis.

It is a fact never to be lost sight of that the danger that comes to a patient from a burn is not in direct proportion to its depth, or to the tissue-destruction. It is the amount of surface injured rather than any other point, unless, of course, some vital organ is irreparably affected by the heat, that renders burns dangerous. By this is meant that a slight burn affecting a large area of the body is more dangerous than a severe one which destroys a small part of the economy. A burn which is so slight that it would produce but little inconvenience, if only a small area was affected, will prove mortal if a considerable portion of the body is so attacked. A patient may suffer a burn that will destroy a good portion of his arm, and recover—yet, if lightly burned on the chest or abdomen, he will be hopeless, if the area is large. The extent of burned area is a vital point in the prognosis of burns. It has been reduced to very accurate principles by correct observers. It is said, and this is borne out by the most accurate European and American observers, that if one-seventh of the surface of the body is burned, the prognosis is grave—if more than this is affected, the result is uniformly fatal. This is a rule of prognosis that is held in England and on the continent of Europe, and in my experience in twenty-five years' practice I have never known one exception to it. I have always, in my consultations and my private practice, found this an invariable rule of prognosis. It is, I believe, the wise course to advise the friends or parents of the gravity of what seems very slight burns. In other words, we must instruct them that danger lurks in the extent of the surface burned. This will save many physicians from the deep mortification that must come to one who misleads his patient or his friends by giving voice to a false prognosis.

In the treatment of burns, one of the first demands is to relieve the shock. Shock is responsible for many deaths in burns. In fact, many patients succumb to the shock. When the patient is seen in the article of shock, or is threatened with it, he should be put in a bath of 105° F., and an injection in the subcutaneous tissue should be made of normal salt solution. He should have an hypodermic injection of strychnine, and hot brandy and milk and water should be administered per os if the patient is able to take them. We should keep the patient well covered, and see that none of his strength is wasted in supporting his body, or in any other way. The application to the burned surface of that old familiar dressing-lint soaked in a mixture composed of equal parts of linseed oil and lime water, has done good surface to many physicians in all the years that it has been known, but that we have a better way of answering the demands in a case of this kind there is, to my mind, no doubt. This old-style dressing is most disgusting in its odor; in fact, it is highly repulsive. Again, oily dressings absorb nothing, and they mix with none of the discharges of the burned surface, and, therefore, are open to objections. They may, I think, greatly aid in the septic infection, in the manner outlined, and this is to be as much avoided

as possible, because I think that the self-infection is one of the principal sources of danger, and to it we can logically look for an explanation of the large percentage of mortality.

The dressing which I now rely upon consists in the application of absorbent lint which has been soaked in a saturated solution of boric acid. I apply this wet, being sure, however, never to apply the dressing which is cold. I use a tepid solution of boric acid. Just here let me say that before applying this dressing I open the blisters, drain off the liquid and sprinkle some boric acid on the exposed surface. The lint is put entirely over the burned surface, and over this is put covering made of wider cloths that can be easily removed. I do not approve of the removal of the dressing so long as the patient is comfortable and the temperature normal. If there is considerable discharge from the burned area the lint can be covered with boric acid from time to time. This exerts a proper influence on the burn. The outer cloth advised can be removed without trouble, and this will aid in removing much odor and discharge.

When a burn affects the hand or foot it will often require much ingenuity to prevent deformity. Very often it is a good idea to keep the hand in a splint, and to watch it very carefully in order to avoid deformities that very often ensue.

In the treatment of burns I have often called the attention of physicians I saw in consultations to the fact that anemia was slowly developing. This is the outcome of lack of feeding. These patients are to be fed adequately and systematically. If given his own way one of these patients—one with a considerable burn—will consume an amount of food altogether inadequate to the needs of the system. If this is necessary, I resort to forced feeding. It is a good idea to give concentrated foods, and to get our patient to eat whether he feels so disposed or not. I am morally sure the outlet of death from burns would be less if nutrition was maintained better than it is often done. I find it highly important to begin to look after this from my first visit.

[Written for the MEDICAL BRIEF.]

Venesection as a Remedy for the Premonitory Symptoms of Puerperal Convulsions.

BY H. J. PARKER, M. D.,
Clayton, Ill.

According to the old authors, Churchill, Mendenhall, etc., venesection is the only reliable remedy for puerperal convulsions, and should be resorted to as a preventive measure on the appearance of the premonitory symptoms of headache, buzzing in the ears, and giddiness.

At the present time and in the person of my present wife, I have the first case where I have resorted to the remedy as a preventive. The patient is a primipara, aged thirty-six, and, being a large, fleshy blonde, when she became enceinte, I said to her, "You are a good subject for puerperal convulsions," yet I told her none of the symptoms, preferring that she mention them as they might arise.

At the sixth month urine became scanty and albuminous, feet swollen. Laxatives, diuretics, spare diet.

At six and one-half months, headaches.

At seven months, ringing and fullness of ears.

I now began to grow uneasy, and to watch for developments.

At seven and one-half months, she felt very dizzy-headed on attempting to rise one morning. She lay down a little while, and on attempting to rise again the symptom returned.

I now took a quart of blood from her arm. The giddiness disappeared at once, and though it returned slightly a few times during the day, it, together with the headaches and buzzing in the ears, gradually vanished.

The patient went on to within one week of full term, and was delivered of a living child. Mother and child doing well. Had the symptoms returned I would have bled again. The treatment is according to the old authors. Modern authors advocate abortion and various medicines for puerperal convulsions. I have seen all plans fail save venesection, and that has never failed me.

Book Notices.

GRUNDZÜGE DER PSYCHIATRIE (Fundamental Features of Psychiatry.)—By Franz C. R. Eschle, M. D., Director of the Pflegeanstalt of the Heidelberg District at Sinsheim a/E. Berlin and Vienna. VII. 297 pp. Large 8vo.

This book has been written with scientific thoroughness, and at the same elementary clearness for the use of physicians and jurists, psychologists and pedagogues. In the preface the author emphasizes the fact that his presentation of the subject is from a more general point of view than that of one-sided specialists, that he continually points to the coherence of all branches of medicine, at the same time taking into account both the efforts at unification in medicine and the stupendous changes that have taken place during the last decade in the field treated of, and establishing the connection between antiquated and modern psychiatry. Eschle's work starts chiefly from the practical point of view, prognosis and therapy occupying a relatively large space. The clinical part is preceded by a section on nature and development of insanity, which treats of general conditions, and, in three chapters of elementary psychic derangements, which are classified as distinctive, effective and (originary) appetitive insufficiencies. The second section comprises the pathological pictures of insanity. The third section, which is of especially practical value, deals with the forensic importance of dubious states of the mind. The oftener one is in a position to pass judgment on the anomalies of psychic life, not only from a clinical, but also forensic point of view, the more readily will he recognize the peculiar difficulties of this task, and the more thankful will he be for the councils here tendered under the guiding influence of a jurisconsult, and constructed on a foundation of vast experience, at the same time taking the literature into critical consideration. As regards the relations of syphilis to nervous derangements, Eschle adopts Rosenbach's position, whereas otherwise nomenclature and conception correspond with Krepelin's axioms.

The work is built up on broad viewpoints, and is written throughout with essential preciseness, always giving reliable information to both physician and jurist. An English translation would, no doubt, be highly appreciated.

THE OPERATION, CARE AND REPAIR OF AUTOMOBILES. Edited from the files of the *Horseless Age*, by Albert L. Clough. New York: The Horseless Age, Publishers. Price, $1.10.

The owner of an automobile should be posted in regard to its mechanism and care and repair, even though he has an experienced man to run it; he should understand the construction and mode of action of the various parts, and have a working knowledge of the cardinal principles of electricity and magnetism, and be able to stand at the helm and govern. It will not only be satisfactory for the owner to know the elementary principles, but to go deeper into the construction and vital principles of the machine, so as to be able to make minor repairs, and thus save much in repair of maintenance. So many physicians are now owners of machines that this work will appeal to them. The automobile is yet an intricate machine, and should be treated accordingly; therefore, any work that gives definite information should be secured by all who have or desire an automobile.

DIAGNOSTICS OF THE DISEASES OF CHILDREN. By Le Grand Kerr, M. D., Professor of the Diseases of Children in the Brooklyn Post-Graduate Medical School. Pediatrist to the Swedish Hospital in Brooklyn, Attending Pediatrist to the Williamsburg Hospital, Brooklyn. Fully illustrated. Philadelphia and London: W. B. Saunders Company. Price, cloth, $5.00; half morocco, $6.50.

Diagnosis in diseases of children is a pretty intricate problem. There are so many difficulties, owing, at times, to the fact that the child is too young to locate even the trouble, and then the statements of an anxious mother or nurse are misleading. It is the correct thing to read all one can gain in relation to child life, and a thorough knowledge of previous condition of father and mother to thoroughly give the child a "square deal" in its troubles. Symptoms, at times, are the only guide, and even this is a guess. This work is full of ideas, and should be read by every family physician.

AMERICAN PRACTICE OF SURGERY. A Complete System of the Science and Art of Surgery, by Representative Surgeons of the United States and Canada. Editors: Joseph D. Bryant, M. D., LL. D., and Albert H. Buck, M. D., of New York City. Complete in eight volumes. Profusely illustrated. Volume III. New York: William Wood & Co. Price, per volume, extra muslin, $7.00; brown leather, $8.00; morocco, $9.00.

As we have stated in a previous review, this work is purely American, and no nation can produce the equal of an American surgeon in daring and successful results. Our most successful operators had their beginning in the crossroads of this great and progressive country. The contributors of this volume bear the names of the men who have made surgery a science. It contains such names as Duncan Eve, John Shelton Horsley, Charles Field Mason, John Chadwick Oliver, Charles Fairbank Painter, Roswell Park, George A. Peters, Alexander Primrose, George Gibier Rambaud, Channing Chamberlain Simmons and T. Turner Thomas. Such names as above noted gives a prestige that can not be surpassed by any volume on surgical subjects. This work is purely American, and as such, should have the prestige among American surgeons. The rapid sale accorded it shows the appreciation in which it is held, not only in America but among our foreign friends who appreciate good work.

DISEASES OF THE RECTUM. Their consequences and Non-Surgical Treatment. By W. C. Brinkerhoff, M. D. Chicago: Orban Publishing Co. Price, $2.00.

Often diseases peculiar to the rectum are but casually diagnosed and treated, while a thorough examination should be made, and the case treated in a scientific manner, for if this is not done properly the whole system is deranged, and complications arise. In making operations for rectal troubles great care should be taken lest you injure some muscles that may weaken the parts almost irreparably. Where surgery is not absolutely necessary the injection method, as used by the author, is all that is necessary. "There probably is no organ of the human body wherein normal conditions are so essential to local comfort and good general health; no organ that, when diseased, gives rise to symptoms so acute, so pronounced and so severe; no organ that produces more serious, more remote and more misleading reflex symptoms, and, at the same time, no organ that can be so seriously and dangerously diseased, without arousing suspicions of the patient or physician, as the rectum." It will prove interesting to practitioner and student to read this work.

MANUAL OF DISEASES OF THE EYE. For Students and General Practitioners. By Chares H. May, M. D., Chief of Clinic and Instructor in Ophthalmology, College of Physicians and Surgeons, Medical Department, Columbia University, New York, 1890-1903; Ophthalmic Surgeon to the City Hospitals, Randall's Island, New York; Consulting Ophthalmologist to the French Hospital, to the Governeur Hospital, and to the Red Cross Hospital, New York; Adjunct Ophthalmic Surgeon to Mt. Sinai Hospital, New York, etc. Fifth edition, revised. With three hundred and sixty-two original illustrations, including twenty-two plates, with sixty-two colored figures. New York: William Wood & Co. Price, $2.00.

The general practitioner, as well as the student, will find in this work a concise, practical and systematic treatise that will give the foundation for diagnosis and treatment, especially of the minor ailments, before it is found necessary to place in charge of the specialist. This is such a delicate member that great care should be taken in treating it, therefore the practitioner should be thoroughly posted.

SURGICAL DISEASES OF THE CHEST. By Carl Beck, M. D., Professor of Surgery in the New York Post-Graduate School and Hospital, etc. With sixteen colored and one hundred and sixty-two other illustrations. Philadelphia: P. Blakiston's Son & Co. Price, $5.00.

This is a very important field in surgery, and the literature on this subject is meager, therefore this work, by the eminent gentleman—Dr. Carl Beck—comes to us fraught with much usefulness, especially as great stress has been laid on diagnostic points, and the elegant illustrations are so suggestive of an intelligent reading, and useful application. Not only surgeons but practitioners should be interested in such a work, as they all know the value of a thorough diagnosis before the actual surgical operation is found necessary.

Editorial.

Vale!

The Editor, Publisher and Proprietor of THE MEDICAL BRIEF has reached the time when he is compelled, by advancing age and certain physical disabilities following in its train, to bid adieu to the thousands of friends—subscribers and advertisers alike—whose support and encouragement he has enjoyed, and he hopes, deserved, throughout the thirty-five years the BRIEF has been published.

The writer is in his seventy-second year. He has been an active worker throughout his life; and since his early manhood almost his entire energies have been monopolized by the responsibilities which the editing and publishing of the BRIEF have imposed.

He was born with an independent mind. He has always had opinions of his own, and his nature is such that for these opinions he can not help from fighting, at whatever expenditure of money or physical effort. But the time has come when he feels that he would like to rest—to get away from all turmoil and strife, and for the remainder of his years to pursue the even tenor of his way "along the cool, sequestered vale of life." Consequently he has sold the BRIEF, and has retired from all business of every kind. He believes he has earned the rest he now covets and proposes to take, and that his thousands of friends among the physicians of the country will not begrudge it to him.

The BRIEF has always been his *Benjamin*—his best beloved! Into its pages he has put his best thought and intellectual effort. Its editorials, particularly, have been the very coinages of his brain. He has loved this journal with all the affection a devoted parent can bestow upon a favorite child. And he parts from it now with a feeling of sadness which is only assuaged by the knowledge that it is all for the best. The comforting thought, too, comes to him that it will not die. Mr. Henry R. Strong, to whom he has sold it, he has known for many years.

He is an able and honorable gentleman, and has abundant capital. He is, besides, a very successful publisher in another line, and the writer, therefore, believes that the future of the BRIEF is safe in his hands. And he asks for him the same hearty support and encouragement that he himself has so long enjoyed. And if he did not believe he would deserve it, he would never have sold it to him.

Over the future destiny of the BRIEF its founder and present editor will have no control. Nor can he be held responsible for any policy it may hereafter pursue. But he has no fear that it will deteriorate in standing, quality or influence. He hopes, rather, that the younger and more active hands into which it falls will improve on his efforts, and make the BRIEF better and more influential than it ever was.

And now, once more, he begs to make his grateful acknowledgments to the friends and subscribers who have been with him all these many years. For each and every one of them he wishes the blessings of health, long life and prosperity. May all the good things of this world be theirs; and, finally, when the end shall come, as come it must to all of us, may the Great Author of our being take them into His kind and gentle care.

And now, dear friends, I bid you good bye. J. J. LAWRENCE.

And Now for the Future!

Beginning with the January issue, THE MEDICAL BRIEF passes into new hands.

It is not without some feelings of diffidence that the new owner assumes responsibility for its future destiny.

The journal has had so long and so eventful a career, and the personality of its distinguished founder and editor has shone out so conspicuously in its pages, that his retirement can not fail to be noticed and to occasion regret among the thousands of physicians who have read after him these many years.

And yet, the future proprietor hopes, by a considerable broadening of its scope, by the introduction of new features already in contemplation but not fully matured, and by the aid of the best contributors in America and Europe, ultimately to so improve the paper in every way that it shall be of more real and substantial use to its subscribers than it has even been in the past.

The constant purpose shall be to make the BRIEF strictly a medical paper, and while the highest degree of scientific merit will be aimed at, this shall always have a practical setting. And in this endeavor to make the paper the best of its kind published, no amount of capital or effort will be spared.

The new proprietor hopes, also, that, wide as its circle of readers has always been, it will be extended in the future, and that, with the broadening of its field, the BRIEF shall be an influence for good, and shall be an ever-present help to the busy practitioner, for whom it is intended. And he asks the indulgence of all old patrons until such a time as his promises can be tested by accomplished results. HENRY R. STRONG.

Natural Religion.

Mankind is very slow to learn what is nevertheless an inexorable truth, that not one of God's laws can be violated without provoking the natural penalty attached to such violation. No physical, intellectual, moral, spiritual, or other law can be violated with impunity. The penalty is as inevitable as the rising and the setting of the sun. We do not always see the sun rise and set, nor are we always able to trace our sufferings to the broken law. It is there just the same, for they are inseparable.

It makes no difference whether an offender sins in ignorance or wilfully. Nature takes no cognizance of intention. Her laws operate inflexibly without regard to the circumstances. The man who takes a lethal dose of strychnine, whether he does so knowingly or by mistake, dies.

Unfortunately, the Church has always taught that forgiveness removes the penalty of wrong-doing. In this way she has been a stumbling-block in the path of men by preventing them from learning their lesson as easily and quickly as they otherwise would. In the very nature of things it is impossible that forgiveness should take away the penalty of broken law. Yet people are anxious to believe it; and the Church encourages them in

doing so. Hence we continue to grope and stumble instead of laying hold of and being governed by the knowledge of the workings of natural law.

Every sane man knows intuitively what is right and wrong; if he does not he has one great precept to which he can refer his course for guidance. "Do unto others as ye would have them do unto you." If he holds steadfastly to this and looks facts courageously in the face, he can not go far wrong. Anyhow, he will have to accept the result of his deeds, whatever their nature. The sooner mankind learns that there can be no juggling, no shirking, but that we must pay the price in every single instance, the sooner we will begin to reap the harvests of our knowledge.

It is true we sometimes reap what we don't sow, but we always reap what we do. The man who does that which injures his self-respect becomes more callous to just that extent. The delicate, inner promptings are less true in their workings. The fine mechanism of the conscience becomes disordered. Then the man is like a ship whose rudder has been injured.

Natural religion is so simple that few are able to accept it. The majority of people do as they wish and shut their eyes to the consequences. Some scapegoat can be found. This knowledge is of more importance to doctors than to any other class of people, since to them is entrusted the life, health and happiness of their patients. The few principles involved in natural religion will sometimes do more to restore the sick to health and usefulness than drugs, for, important as they are, the relief they afford is but a detail.

The Church, like many other institutions, has been led astray by the temptation to establish man's dependence on her. She has been unwilling to see him self-reliant, lest he cut the apron-strings. When a man knows positively that his course in life is hedged all about by invisible natural laws, the breaking of which must be followed by suffering and scars, then will he elect to follow the right cheerfully, joyously. The great work of Christ for civilization will be nearing its accomplishment. The truth will set us free.

Inefficiency.

Nearly every day we read in the newspapers of some horrible railroad accident. These accidents occur with such frequency people are getting afraid to travel. Every one is asking why there are so many accidents. The reason may be summed up in one word, inefficiency. Railroad employes do not attend to their business properly.

The popular idea nowadays seems to be for each man to do as little work as he can and still hold his job. These dreadful accidents would not happen if railroad employes would concentrate their minds on their duties. The popular idea of doing as little as possible for the money one receives is all wrong. The correct idea is to earn all one is paid and more, and directly he will be getting more.

Careful attention to one's individual duties would prevent the thousand and one accidents which almost daily shock us. Each man is benefited by the other man's doing his duty properly. Seldom does an accident occur which does not reveal stupidity or carelessness at the bottom. The ease with which these horrors could have been averted in most cases incenses people.

Much of this state of affairs has been brought about by the yellow newspapers. Whenever a man, by hard thought and close attention to business, becomes prosperous, they begin harping about his money, without stopping to think that he is precisely the man who employs others. The man who is industrious, economical and accumulates money is the one who starts enterprises and provides opportunities for other people. Work and wages are necessities of our civilization, and the man who makes them possible is entitled to our respect and regard.

This preaching of discontent is the principal cause of so much inefficiency. It is a bad thing for the individual and a bad thing for the people. The individual loses sight of the fact that merit is the basis of promotion, and the public suffers through his half-hearted work. The great secret of life, after all, is paying for what you get. The man who gives better service than he is paid for is never in debt to any one and is preparing for a better job.

The motto of the world should be: Do your duty and get others to do the same. Mutual benefit is the result, and the individual can feel assured that he is building better than he knows. He can well afford to trust the future for the outcome if he lives up to the principles involved in a successful career.

Those who criticize and abuse successful people in order to create prejudice do not advance their own selfish interests in any way and do not greatly injure the successful person, but they do do a great deal of harm to society at large in arousing evil passions and inculcating false ideas.

The Jap.

You have, of course, noticed that California is opposed to unrestricted immigration from Japan. We already know that she is opposed to Chinese immigration, and when we come to know as much about the Jap as about the Chinese, we will be obliged to feel that the yellow peril is not a bugaboo, but a real menace.

California can not afford to ignore the problem of the Jap. We already know that the Jap, like the Chinese, quickly learns to do the white man's work, and will take a job at much less than the white man can live on. The Jap in his own country is selfish and intolerant of the white man, except as a buyer of curios. Industrially, the white man is never welcome.

The prevailing idea that the Jap is a charming little fellow is based on superficial observation. That he is clever, all acknowledge; but that he is correspondingly lacking in moral sense, a number of instances of their dealings, of which the following is a typical example, clearly prove.

Several years ago a Japanese, with several assistants, went to St. Petersburg and opened a tea house which, cleverly managed, prospered greatly, and the proprietor and his assistants made friends among the patrons. At length, the Japs expressed a desire to become naturalized Russians, members of the orthodox Church, and to marry and settle down in the country of their adoption. The Russians were flattered by this preference for their country and institutions. Accordingly they aided and abetted the Japs until all their wishes were accomplished. All went well until the breaking out of war, when suddenly the Japs were missing, having abandoned home and families. It transpired that these men were officers in the Japanese army, who took with them to headquarters all the information and confidence gathered during those years spent in the heart of the enemy.

Treachery such as this is very revolting to the Anglo-Saxon. No cleverness, no success, can redeem it. A race which is at once thoroughly unscrupulous and clever is bound to obtain a certain amount of success and recognition, but the Anglo-Saxon can never dwell in peace, side by side, with a people who are both ambitious and lacking in moral sense.

People living on the Pacific Coast, who have had practical dealings with the Japs, assert that they are given to trickery, that they are dishonest, untruthful, and generally unreliable, under a fair seeming of tact and politeness. The Chinese, on the other hand, while not so pleasing in manner, are honest, truthful and generally dependable.

A conservative estimate of the number of Japanese in the United States today places the number at one hundred thousand, and immigration is constantly increasing. As the Jap does not assimilate, and can work cheaper than the white man, this increasing stream of immigration constitutes a real Pacific Coast problem.

Before taking sides with the Japs or condemning our friends on the Pacific coast for the stand they have taken in this matter, we ought to know more about it. At least, we ought not to jump to conclusions based on long-range observations or sentimental considerations.

Better to Be a Man Than a Peg.

In this day of organizations, combines and trusts, the rights of the individual are lost sight of. The average man who joins an organization is simply a peg, to be moved around to suit the notions of a few.

There are men in organizations who are not pegs, simply because they do not

submit to organization rule, but continue to hold their own course, regardless of what others may say or think. Many men can not do this, however, and are hopelessly submerged, their liberty lost, their rights infringed, until they are mere pegs, to be moved here and there, at the dictation of a few ruling spirits.

Such a man, if left to himself, thrown upon his own resources, compelled to grapple with circumstances, to think, plan, execute independently, develops and strengthens his character, and becomes a capable man, a power for good, and does all within his limitations that a man can accomplish.

The same man, in the grip of organization control, becomes narrower, feebler, until he is nothing but an automaton—stunted, wretched, and useful only to be moved about in another's game.

The organization might be a good thing, if it carried out the designs for which it was formed, but it invariably degenerates into a machine, controlled by the few, and used to suit their purposes. A few do the thinking and the majority submit to their dictation, without realizing that they are wronging themselves and the cause of progress.

The natural love of independent research and discovery suffers when a man is hedged all around by restrictions and prohibitions—that is, it would, if he were to submit to such treatment. Fortunately, the American doctor does not take kindly to leading strings.

The American doctor is going to do what suits *him*.

The MEDICAL BRIEF believes that the individual doctor is able to make his own way without being incessantly told what to do. All this guiding and protecting is gratuitous. It is the outgrowth of abnormal egotism. Give the doctor food for thought, present the other side of all questions for his consideration, stimulate him to do and dare, to struggle and thirst after knowledge, give him the fullest liberty and opportunity, then let him alone and he will arrive all right.

If the average doctor could appreciate his true worth, if he realized what self-reliance and liberty have done and are doing for him, if he could get an outside view of the courage, the strength, the self-confidence, the resourcefulness, the perseverance in the face of difficulties, the many fine qualities that have been bred in him by independence, the proposition to subordinate his individuality—to reduce him to the level of a peg in a machine, would awaken a revolt commensurate with the danger which threatens him.

No man can ever amount to anything who is pulled this way and that to serve somebody else's ends.

Too Much Law.

In the early days of the Republic, men sought to have as few laws as possible beyond those needed to secure the individual in peaceful possession of the fruits of his labor and to settle disputes which the parties, themselves, were unable to settle. All questions relating to a man's health, his conscience, freedom of opinion, etc., were left to his own common-sense and discretion.

This policy made the United States what it is today. Men's energies were unhampered. The incentive to individual thought and action was strong. A man found his level sooner. Experience kept school and great things were accomplished.

Gradually a change has come about. Nowadays, the tendency is to make a law to remedy every evil that crops up, regardless of the fact that it is only by education that we make any real progress. Evils tend to correct themselves if left alone, but no law can legislate a fool into a wise man.

The doctor is in a position to extend a helping hand to mankind by educating them to have proper standards of judgment. But as an educated man, himself, he is consistently opposed to laws which, under the pretense of protecting people, really stifle those instincts and energies which would otherwise develop and broaden people, and consequently make for progress.

The decision in the Bishop case, of a year or two ago, that parents are not legally obliged to call in a physician to a sick child is probably correct. Of course, it seems hard that a child should die without medical attendance, yet the

parents might have called in a man who had a diploma, yet whose practice was equivalent to doing nothing. If people can be legally compelled to employ a doctor, it is easy to go a step further and declare that they must select a particular pathy. Laws which encroach upon individual liberty always work more harm than good. Better freedom with its mistakes and occasional tragedies than the iron compulsion of law which leaves no room for choice and teaches no lesson.

There is more danger in too much law than in too little. Laws passed to regulate people are easily turned into a source of blackmail. We should never forget that the best governed country is also the least governed. Fewer laws, of a fundamental character, and those enforced, is sound social policy. Let us not endanger the magnificent growth and prosperity of the United States by retrograding to the old monarchical idea of having the government do too much, instead of relying on our own powers. Let us safeguard our country while there is time by a vigorous opposition to all laws which hamper the individual under whatsoever specious plea they may be presented.

Intuition.

Doctor, did you ever stop to ask yourself what intuition is? Is there really such a thing? It has been denominated the sixth sense. It is a spiritual sense and can not be located. Its existence can only be proved by its findings. It can not be called "unconscious cerebration," since it seems to need no facts to go on, yet the results it arrives at are real.

For instance, dogs and babies always know their friends by intuition. A dog can divine a man's moods and has his own way of showing sympathetic comprehension of joy and sadness. If two men go out for a walk and are joined by a dog, the dog will instantly choose one of the men to follow, and it will always be the one who likes dogs.

No doctor should choose diseases of children as his specialty unless he really loves children. Love is a close observer and a fine manager. If the baby stretches out its arms to be taken when the doctor enters the room, then you can be sure he will do well in that line of practice. Sympathy is absolutely necessary to a good understanding of a patient's condition, more than ever so in the case of children when the doctor must make his diagnosis unaided by any subjective information.

Don't flatter yourself that you can deceive a baby by any amount of art. If you are not really interested in children, the baby will know it instantly. The averted face and wail of protest will brand you as a fraud instantly.

By the way, love of one's work is the secret of success in most callings. If you love your work, you are sure to be steadfast, persistent, progressive, and these are the conditions which lead to success.

All our knowledge of religion is based on intuition. Religion is a series of convictions based on the experience of life. How we get them we do not know. We sense them spiritually, and intuition is the word we use to denote the process; but while we can not explain, we feel just as sure as if we were talking demonstrated certainties instead of faith.

People used to think religion was a matter of profession. Terrible cruelties were committed in the name of religion because of this misunderstanding. As humanity has deepened and broadened and mellowed under the workings of the leaven of Christ, our conception of religion has steadily risen. We now know that while all religion is fundamentally the same, every man has his own individual brand, differing only in minor particulars.

We know, too, that no sect has any proof to offer us of man's future estate. There is no such thing as revealed religion, except what can be gotten from analogy and the observance of Nature's laws. Our knowledge of religion is purely intuitive. All races and all ages have had it. It has been perverted and obscured at times, but it is and always has been an innate part of man. Right living makes it shine out ever clearer.

Whatever material science may have to say about it, there is such a thing as intuition, and in its apprehension of facts it is quicker and more correct than reason.

THE MEDICAL BRIEF

J. J. LAWRENCE, A. M., M. D.,
EDITOR AND PROPRIETOR,
NINTH AND OLIVE STREETS,
ST. LOUIS, MO.
NEW YORK OFFICE, ASTOR COURT BLDG.
FOREIGN OFFICE:

These rates include postage.
Advertising rates sent on application.

All subscriptions will be discontinued at expiration unless renewed.
The Medical Brief will not be sent unless paid for in advance.
One Dollar per year in advance.

Write *only on one side* of the paper.
See how *short* and *plain* you can write.
Write articles intended for publication, and matter for editor, *on separate pieces of paper.*
Articles sent for publication in the MEDICAL BRIEF *must not contain more than seven hundred words.* Short, practical, *brief items* always wanted.
The MEDICAL BRIEF is mailed on the first of each month. If a number fails to reach you we will supply it, provided we are notified within a month.

☞ The Editor is not responsible for the articles of contributors. The MEDICAL BRIEF aims to publish articles on both sides of a question.

The MEDICAL BRIEF has the largest paid circulation of any medical journal published anywhere.

[Written for the MEDICAL BRIEF.]

Adrenal Tumor of Vagina Secondary to Malignant Hypernephroma of the Kidney.

BY ALBAN DORAN, F. R., C. S.,
Surgeon to the Samaritan Free Hospital; Past President of the Obstetrical Society of London.
London, England.

Dwelling as much as possible on matters of clinical interest, and avoiding deep pathological subtleties, I will relate a remarkable case in my own practice where a malignant tumor developed in the vagina of a middle-aged woman, subject to enlarged kidney. I removed the kidney, and it was afterwards found that the renal growth was a hypernephroma, a malignant tumor originating in adrenal tissue in that organ, while the vaginal growth was not a coincident primary sarcoma, but a secondary adrenal tumor. A very similar case, as I will explain, was under observation in London at the same time as my own.

My patient was a very sallow-complexioned married woman, aged forty, who called in her doctor on account of an attack of shivering, sweating and fever, early last autumn. A tumor was detected in the vagina, a racemose body attached by a well-defined pedicle to the lower part of the anterior vaginal wall. There were also three sessile growths in the posterior wall, one being jugulated. A small, movable tumor occupied the right iliac fossa. The lobules of the pedunculated growth were shed from time to time, and I sent them to Mr. Shattock, of the Royal College of Surgeons, and to my colleague, Dr. Cathbert Lockyer for examination. In November, 1906, I removed the abdominal tumor. It was a typical malignant adrenal growth in the lower part of the right kidney, which had become twisted in its pedicle so that the tumor lay uppermost, touching the liver, whilst the upper pole of the kidney lay downwards, rotated on the lower part of the lumbar spine. As there was considerable shock, I postponed the removal of the original growths. The patient survived the nephrectomy three months, after declining to allow a second operation for the removal of the polypus and the sessile tumors in the vagina. Until her death, lobules continued to come away from the vagina, and symptoms of pulmonory complication were observed. At the *post-mortem* secondary deposits were found in the liver, lungs and intestines. Under the microscope it was found that the vaginal polypus and the omental and visceral deposits were histologically identical with the renal tumor, a malignant adrenal growth, which was declared by the pathologists above mentioned to be an adrenal carcinoma, and not sarcomatous.

Just before I brought forward my case at a meeting of the Obstetrical Society of London, I mentioned it to Dr. Beckett-Avery, who, to my surprise, informed me that he had recently been in-

vestigating another, most striking for its similarity with my own, excepting that one clinical feature, sloughing and general septic infection, was absent. Beckett-Avery's patient was fifty-five years of age, alarmed on account of vaginal hemorrhage. A polypoid mass was found attached to the anterior vaginal wall. It was removed, and appeared, on microscopic examination, to be a very vascular sarcoma. A large tumor, occupying the right side of the abdomen, was detected when the patient was in the hospital. The vaginal growth recurred in its former site, and was removed within two months of the first operation. The patient died a month later. The tumor in the abdomen was a hypernephroma of the right kidney; the right suprarenal capsule was normal, but numerous secondary growths, some of large size, were found in the liver and lungs, and on comparing sections of these growths with sections from the vaginal tumors, there could be no doubt that they were all of the adrenal type, secondary to the renal growth.

Dr. Beckett-Avery read brief notes of the above case when my own was brought forward at the Obstetrical Society. In the discussion Dr. Cathbert-Lockyer related how he had watched for nearly ten years a woman subject to uterine fibroid; during the last six months a renal tumor had developed. He had operated on the patient, fifty-seven years of age, a few hours before the discussion was held, removing the diseased kidney, the uterus and also a parovarian cyst. Frozen sections showed the renal tumor to be a benign hypernephroma, an adenoma derived from adrenal "rests" in the kidney. Since this discussion Dr. Lockyer informs me the uterine tumor has been examined, and was found to be a fibro-myoma, including a sarcomatous patch quite free from any adrenal elements, benign or malignant. The third tumor with which this patient was afflicted, the parovarian cyst showed no evidence of malignancy of any type.

Adrenal Tumors—Much has been written during the past twenty years, both in Europe and America, about "hypernephroma" and "adrenal" tumors. The literature of the subject is now very voluminous and hard to study. We must be careful to avoid confusing these new growths with malignant tumors of the suprarenal capsule itself, usually associated with abnormal growths of hair, and sometimes with insanity (Knowsley Thornton). In "hypernephroma," tissue resembling that which makes up part of the suprarenal capsule takes on more or less malignant action. This tissue forms the so-called adrenal "rests" in the substance of the kidney. Hypernephroma has been found in patients of almost every age. Dr. William S. Cheesman, of Auburn, N. Y., reported in the "Annals of Surgery," for January, 1907, a case where he removed a hypernephroma weighing four and a quarter pounds from an infant twenty months of age. This disease of the kidney seems very malignant; secondary deposits in the lungs and liver developing early. The suprarenal capsules themselves do not appear to be involved.

In the cases which I have related there can be no doubt that the vaginal growths were secondary to the renal tumors, unless we accept a theory suggested to me by Mr. Bland-Sutton that the disease in my patient's case was a general "lighting up" of malignant change in "rests" already present in the vagina as well as in the kidney; he even expressed an opinion that the vaginal growth might have been congenital, and also the primary seat of that change. We will assume, however, that in the cases under consideration the vaginal tumor was secondary.

The existence of new growths of the same type higher up the genital tract, has been recognized for some time. Dr. Eastwood's important monograph on the occurrence in the pelvis of malignant tumors originating from adrenal remnants, published five years ago in the fifty-third volume of the "Transactions of the Pathological Society of London," remains the best summary of the subject. Excluding instances of adrenal tumors in the male genital tract, we may note Marchand's case of adenoma of an accessory adrenal in the forward ligament of a woman aged fifty. Eastwood himself furnishes medical literature with the original report of an adrenal tumor connected with the uterus. The patient was a sterile woman, aged forty-eight, who had married when

thirty-eight years of age, the menopause occurring at as early an age as forty. For fifteen months the patient had been troubled with sacral and hypogastric pains, associated with irregular, dark-brown, and sometimes offensive, vaginal discharge. A solid tumor, movable and dull on percussion, reached midway to the umbilicus. Hyperectomy was performed. At the operation the presenting part of the tumor was found to be cystic, and two pints of yellowish fluid had to be drained off before the solid part of the new growth could be delivered through the abdominal wound. The tumor appeared to spring from the uterus, which was amputated through the top of the cervix, where the tissues appeared perfectly healthy. Both ovaries were removed at the same time, and found to be natural. No other abnormalities were detected. When examined one year later there was no evidence of recurrence, and no other sign of disease. Such was the original report, and it seems clear that neither kidney was the seat of a new growth. Dr. Eastwood has recently informed me that the patient, shortly after the above-noted examination, began to ail again, and clear evidence of general dissemination was detected. At the time of her death she was not under Dr. Eastwood's observation, and it appears that, unfortunately, there was no *post-mortem* examination.

Two cases of alleged adrenal tumor of the ovaries are included in Dr. Eastwood's monograph. The first was recorded by Neham. A suprarenal "rest" developed in the neighborhood of a cystic ovary, and invaded the cyst wall. The second, originally described by Weiss, occurred in a girl aged seventeen. A tumor developed in a suprarenal "rest," situated between the layers of the broad ligament. It first invaded the hilum of the ovary, and ultimately came to lie upon the fundus uteri. The enlarged and partially infiltrated ovary formed an excrescence on its upper aspect. Such was Weiss' interpretation of the pathology of his case, but he himself admits that the histological characters of the tumor differed much from those of a pure adrenal "rest." Eastwood, therefore, "can not think that Weiss has successfully excluded the possibility of his case being really an angiosarcoma commencing about the hilum of the ovary, and subsequently invading the broad ligament."

In dismissing the subject of adrenal tumors in the upper part of the female genital tract, let us bear in mind this uncertainty about angiosarcoma and adrenal tumor. The tissues of the latter type of new growth are often extremely vascular. Such was the case both in my own specimen and in Dr. Beckett-Avery's, where the vagina was the seat of the secondary growth, but I shall presently refer to Klien's case of vaginal sarcoma, which was described as an angio-endothelioma. If Weiss took a malignant angioma for an adrenal tumor, Klien may have made the reverse error. Perhaps both these writers were correct; yet, if so, it does not follow that others may have not fallen into an error of the kind above suggested. In other words, adrenal tumors of the vagina may have been misinterpreted and recorded under wrong titles.

Hitherto, however, whilst we see that adrenal tumors of the upper portion of the genital tract have been already reported, the two cases which I relate are the first in which that class of new growth has been recognized in the vagina.

Solid Vaginal Tumors—As in my case and Dr. Beckett-Avery's, the principal vaginal tumor was pedunculated. Theirs simulated a connective tissue tumor of the vagina which, whether innocent or malignant, is frequently attached to the vaginal mucous membrane by a more or less distinct stalk. Primary cancer of the vagina usually appears as a deep ulcer with a hard base, or before ulcerating it may spread superficially over the surface of the vagina, converting it into a rigid tube. Pedunculation seemed practically unknown in this class of new growth until Macnaughton Jones and Lockyer reported, at a meeting of the British Gynecological Society in March, 1907, an instance of primary carcinoma of the vagina, where the new growth was hotryoidal in character, and the deeper part was pedunculated." The patient was a widow, aged sixty-five. This case was exceptional, and therefore we may dismiss carcinoma altogether.

We are bound, on the other hand, to devote some attention to fibroma of the vagina on account of its clinical resemblance to primary sarcoma of the vagina in the adult, and to the secondary adrenal tumor, the subject of this communication. This type of new growth is practically inseparable from myoma.

The best monograph on fibro-myomatous tumors of the vagina is that prepared by Dr. Richard R. Smith, of Grand Rapids, Mich., and published in the forty-fifth volume of the *American Journal of Obstetrics*. He collected one hundred and one cases. In only two was the new growth multiple, a feature of importance, for in sarcoma, as in my adrenal tumor, multiplicity is rare. In twenty-seven cases the tumor was designated as sessile, and in thirty-nine as pedunculated, and although there remain thirty-five cases where no statement is made as to this point, it remains clear that pedunculation is very common.

We must bear in mind Dr. R. H. Smith's important statement that his statistics prove how there is a marked tendency in fibro-myoma of the vagina to undergo necrosis. The same change, as has long been known, is frequent in primary sarcoma of the vagina, and in my own case it gave rise to constitutional symptoms which led to the detection of a tumor. Dr. R. H. Smith's evidence shows that sloughing is not in itself a proof of malignancy.

There remains the type of primary tumors of the vagina which the adrenal new growth in my own case most resembled. That type is specifically known as "primary sarcoma of the vagina in the adult," so as to distinguish it from a yet more malignant type which appears in infancy and childhood. By "primary sarcoma," I understand the adult type. Many authors, such as Veit and Gow, have written on primary sarcoma. Perhaps the best monograph on the subject is that prepared by Jellett and Earl, of Dublin, and published in the fifth volume of the "*Journal of Obstetrics and Gynæcology of the British Empire.*" They tabulated thirty-nine cases where malignancy was undoubted, but the histology of many of these cases remains open to doubt. Thus, seventeen were reported as "spindle-celled," but the authors suspect that at least six out the seventeen were probably endotheliomata. Veit, himself the author of an earlier work on primary sarcoma, warns us therein not to be too hasty in defining the histology of malignant growths in the vagina, or in concluding that they are primary. Klien's case, of which I have already made some mention, is doubtful. Veit suspects that it was a carcinoma. Klien himself classifies it as a lymphangio-endothelioma cavernosum hæmorrhagicum. The new growth appeared as two friable, pedunculated, tuberous, elastic tumors. It was found, under the microscope, to be reticular in structure, with its meshes filled with blood. Now, when we turn to Neusser's treatise on diseases of the suprarenal capsules in Nothnagel's encyclopedia, we find that pathologists have noted how adrenal "rests" in the kidney and elsewhere tend to become malignant. One prominent feature of this degeneration is extreme vascularity, so that the tumor appears almost telangiectatic. Klien's patient suffered from recurrence, but, though watched for a time, she seems to have passed away from his observation, after refusing to return to the hospital. There is, moreover, no mention of any examination of the abdomen during the time that she was being watched. Hence I can not help suspecting that Klien's tumors might have been of adrenal origin, and if not, I must repeat that in other reported cases the adrenal nature of the "primary sarcoma" might have been overlooked, for adrenal tissue is unfamiliar to the gynecologist.

In comparing primary sarcoma with my case of vaginal tumor three other features deserve consideration, namely: Pedunculation, pigmentation and sloughing. Pedunculation is very frequent in primary sarcoma, but it represents a later stage of the sessile tumor, both stages being observed in my adrenal tumor where the growths, as is often the case in primary sarcoma, were multiple. Multiplicity almost proves malignancy, for, as we have seen, Richard H. Smith has shown that not two per cent of fibro-myomas of the vagina are otherwise than single.

Pigmentation is a most interesting feature in primary sarcoma of the vagina, and one of the sessile growths in my own case was pigmented. Boldt, of New York, reported a case before the New York Obstetrical Society last year. The patient was a multipara aged thirty-seven; the tumor, figured in the *American Journal of Obstetrics*, October, 1906, was made up of small, round cells, the deeper being laden with dark pigment. Horn and Moreston, on the Continent of Europe, have both reported instances of pigmentation, but both trace the pigment in the cells to the blood, so that the tumor was only "pseudo-melanotic." Such appeared to be the case in the sessile adrenal growth which I have described above.

Sloughing is very frequently observed in cases of primary sarcoma; indeed, it is probably constant in the later stages. Howard Kelly dwells on this complication which, as he observes, may be the direct cause of death. My experience shows that an adrenal tumor of the vagina tends to slough. When decomposition began in the case which I have related, rigors and fever set in, and not till then was the vaginal tumor discovered. Before death all the vaginal growths had undergone very extensive sloughing.

In two authentic cases of primary sarcoma of the vagina secondary deposits developed in the lungs. During convalescence from the nephrectomy, as I have above stated, symptoms of that complication developed in my own patient. Bearing in mind the two cases, I was therefore led to suspect that the primary seat of the pulmonary deposits was the vaginal growth, but the microscope showed that both were secondary to the renal tumor.

Conclusion—These cases teach us the great importance of careful microscopic research, especially in respect to prognosis, in all cases of connective tissue tumors of the vagina. The fact that a vaginal tumor is histologically of the adrenal type is, as we see from the above cases, highly unfavorable. Its association with a primary hypernephroma of the kidney is particularly grave, as secondary deposits in the viscera, often impossible to diagnose, are usually present at the same time. In my case the tersion and consequent invertion of the affected kidney was a feature of interest to the general surgeon. Nephrectomy for hypernephroma is fairly satisfactory as to ultimate results, provided that no secondary deposits are present. Unfortunately, that was not the case with my patient.

An Investigation into the Modes of Action of the Group of Antiseptics.

BY C. D. F. PHILLIPS, M. D., LL. D. (EDIN.), LL. D. (ABERDEEN), F. R. C. S. (EDIN.), M. R. C. P. (LOND.).

Late Lecturer on Materia Medica at Westminster Hospital, London, and Examiner in the University of Aberdeen, Glasgow and Edinburgh.
London, England.

No. II.

In continuation of this subject I may point out that De la Croix, Miguel and others have followed the line of observation laid down by Koch, and, as they have experimented with the same chemicals, but with a different micro-organism (viz., the non-specific bacterium termo cultivated in meat infusion), a comparison of the results thus gained is interesting:

TABLE II.

	Koch.	De la Croix.	Miguel.
Sublimate Solution.	1:300,000	1:90,208	1:14,300
Oil of Mustard	1: 33,000	1: 3,353	.....
Iodine	.....	1: 5,020	1: 4,000
Salicylic Acid	1: 1,500	1: 1,008	1: 1,000
Boracic Acid	1: 900	1: ——	1: 130
Carbolic Acid	1: 800	1: 669	1: 313
Alcohol	1: 12.5	1: 21	1: 105

Klein, in an elaborate and exhaustive inquiry into the antiseptic properties of phenylproprionic and phenylacetic acid, has, in a yet more striking manner, shown that any generalization from results of the germicide action of one chemical agent on one form of micro-organism to its action upon another is not admissible.

For instance, he finds that a non-specific micrococcus and bacterium termo requires one to two hundred phenylpropionic acid to destroy its vitality, whereas bacillus anthracis requires a solution of one to eight hundred only, both being exposed for the same length of time, and under similar conditions; and, again, the virus of tubercular matter requires to be exposed to a solution of one to two hundred

for ninety-six hours before it loses its activity, whereas that of swine plague is destroyed by being exposed to one to eight hundred for twenty minutes.

Marteris, Weeks, Yerson, and others have compiled long series of tables as to the results gained by exposing various micro-organisms to the action of different antiseptics for variable lengths of time, but our ignorance of many of the fundamental laws which govern the growth and development of these germs, and their adaptability to altered conditions, must make us very cautious in accepting observations which differ so widely from each other, though performed apparently under similar conditions.

In such experiments the chief sources of possible inaccuracy appear to be due to:

1. The fact that some forms of micro-organisms appear to be more virulent than others, though both are of the same species. As an illustration of this may be quoted the fact, that if a healthy mouse be inoculated with the blood of a sheep suffering from anthrax, death results in the course of twenty-four to thirty-six hours, but the converse proposition does not hold good; to a healthy sheep, which is inoculated with the blood of a mouse affected by anthrax, the disease is not communicated from the mouse.

2. The *spores* of those organisms which produce them are much less vulnerable than the *bacilli;* and

3. The bacillus of cultivations is not so well calculated to resist the action of the antiseptic, though equally well able to reproduce the disease. For this reason, therefore, it is most desirable that the micro-organisms thus experimented with, if of a specific character, should be passed from time to time through an animal that is capable of inoculation by the disease, in order to increase and refresh their power and virulence.

Much valuable knowledge may be gained from perusing these results, which distinctly indicate the great service germicides are able to render when direct application is possible to those sites where the septic or zymogen processes are taking place; through their deterrent effect the process may be checked or entirely arrested, either by placing the organisms under such untoward circumstances as to render their further life impossible, or by poisoning the nourishing media, so as to kill the microbes completely.

But these are not the only factors to be taken into consideration, even in regard to the external application of antiseptics, and highly important is the following problem, viz.:

4. What is known regarding the action of germicides on the tissues of the body?

The local action of many of the antiseptics is that of an irritant, even of an escharotic, if used in a sufficiently concentrated form, and there seems but little doubt that a germicide may not only prevent the activity of the microbes present, but, by its stimulating nature, may also act upon the cells of the tissues, and thus produce a more healthy and vigorous condition, which renders them better able to disintegrate the enfeebled germs by which they are infested.

Many of the antiseptics already tabulated are so destructive in their action to living tissues (when sufficiently concentrated to show a germicide action) that they have to be abandoned for all practical purposes, and it does not, with our present knowledge, seem possible to recognize to which reageants the cells of the tissue or the micro-organisms themselves are the first to yield, although it is a most important point to appreciate.

Difficult as the subject is in relation to the *external* application of antiseptics, the difficulty is tenfold increased when we come to consider the value of antiseptics administered *internally*, whether when given by the mouth and absorbed from the alimentary canal or exhibited by subcutaneous methods.

Under these circumstances the problem of the reaction between the cells of the tissues and the antiseptic is of vital importance, and still it is one of which little practically is known. In considering the internal administration of antiseptics it will be necessary to approach the subject under three heads:

1. Do the antiseptics, when administered internally, produce an antiseptic condition of the blood, and the tissues of sufficient concentration to check or arrest the growth of micro-organisms?

2. Do they produce this effect by reacting upon the tissues themselves, and thus enabling them to resist the attacks of the germs?

3. Do they produce their effect by neutralizing the toxic products of the microbes?

1. The internal administration of antiseptics in sufficiently large doses will undoubtedly produce a marked antiseptic action in the alimentary canal, prior to the time when they become absorbed into the blood capillaries and lymphatics, but some of them are very diffusible, and soon make their appearance in the urine, by which channel most of them are very rapidly eliminated. Take, for example, sodium salicylate, which will appear in the urine in from five to eight minutes after administration by the mouth. Thus it will be recognized that the length of time taken by the absorption and the rapidity of elimination of a drug must exert a very distinct effect upon any possible degree of saturation to which the system may be subjected by its exhibition.

This, however, is not the only view to be considered in this relation, for although absorption of an antiseptic may take place, yet during that process there appears to be a very great chemical change brought about in the substance ingested.

The great difficulties which beset such a line of observations are, with our present limited knowledge of physiological chemistry, almost rendered insuperable. Baumann has pointed out that carbolic acid, if administered by the mouth, may be found in the blood as sulpho-carbolates, chiefly of soda, which, though they still possess an antiseptic power, it is of a very much milder nature than the one from which they have taken origin; similarly, again, salicylic acid is transformed into salicylate of soda, and is eliminated as such.

With the view of comparing the power of higher forms of life with the power of *germs* to resist the action of antiseptics, even in very dilute solutions, Richet has conducted some very interesting observations upon fish. He placed fishes in salt water, to which had been previously added sufficient organic matter to allow germs to grow and multiply, but not enough to interfere with the well-being of the fishes. The degrees of concentration of the various antiseptic metallic compounds which could be resisted by the fish, and the effect of the same upon the germs employed, was observed, with the following results:

COMPARATIVE TOXIC INFLUENCES OF THE METALS IN COMBINATION UPON MICROBES AND FISHES.

Metal.	Minimum Dose Expressed in pounds per liter.	
	Arrests Putrefaction.	Kills Fish in Less than 48 Hours.
Mercury	0.0055	0.00029
Zinc	0.026	0.0084
Copper	0.062	0.0033
Cadmium	0.040	0 017
Iron	0.24	0.014
Nickel	0.18	0.125
Barium	9.35	0.78
Lithium	6.9	0.3
Magnesium	7.2	1.5
Ammonium	18.7	0.064
Calcium	30.0	2.4
Sodium	43.0	24.0
Potassium	59.0	0.10
Manganese	7.7	0.3
Cobalt	.....	0.125

Medium Employed—
Sea Water.....900 grammes.
Neutralized Urine.....100 grammes.
Peptone..... 1 gramme.
at 20°C.

The results which were thus gained indicate clearly that the more active antiseptics were much more fatal to the fishes than to the germs, and that in solutions of such concentration as would kill the fish, germs would not even be impeded in their growth.

Too much reliance, however, must not be placed on these results, for although it may not be possible to so saturate the blood, lymph and tissues with an antiseptic as to kill any microbes that may be present, still sufficient may be absorbed without disastrous effect to check and hinder, to some extent, the growth and development of the micro-organisms.

The experiments of Chamberland and Roux have pointed out that very small quantities of some chemical reagents (carbolic acid and potassium bichromate) added to culture media, though not in sufficiently concentrated solution to arrest, but only in some degree to inhibit the growth of the bacillus anthracis, may alter its morphological appearances. This does not appear to be due to any real alterations in the specific characteristics of this organism, but merely a general weak-

ening of its vital power, for no reliable observations have yet been made which will allow the conclusion to be arrived at that by alteration in the processes of culture, or in the nature of the cultivating media, one specie of micro-organism can be merged into and acquire the characteristics of another.

It is, therefore, not an unreasonable hypothesis to adopt that by the continued administration of a suitable antiseptic the blood and lymph, though the latter not so readily as the former, may be brought into such a condition of saturation with an antiseptic that, though the antiseptic may not be present in them in sufficient quantity to arrest the growth, it may be able to inhibit or to alter the vital activity of the micro-organism, so as to render them less virulent, or even inocuous.

The fact is well established that certain chemical preparations, when administered by the mouth, are to be found being eliminated by the various channels of excretion, and, in the case of some of the simpler inorganic salts, unchanged. Hence we are led to the conclusion that they have, in all probability, been absorbed, circulated and discharged without their chemical combination having been broken up. Though this view may hold good for the more simple, it certainly does not for the more complex compounds, the organic combinations being subjected to very elaborate changes when within the circulation, with the result that many varied derivatives are produced from them.

It is also not at all unlikely, as has been mentioned already, that those reageants which exert a marked antiseptic action outside the body may, when absorbed form some entirely different and feebly-germicide product, or even a neutral compound with some of the albuminates or salts of the blood, and so render no material assistance to the object in view.

2. Do antiseptics react upon the tissues of the body, and thus enable them to resist the attacks of the germs?

A large share of the work of destruction of microbes within the body has, by many, rightly or wrongly, been attributed to the white cells of the blood, and with the inference that a small increase in the activity of their functions may cause a more rapid diminution of the microbes. Very little attention has yet been devoted to the study of the action of antiseptics upon the activity of these cells, but Pohl has, in an elaborate research, shown that an increase at any rate in number of the white cells could not be noticeably traced to those antiseptics which have the most prominent position as such. Much more work is needed under this head before any satisfactory facts can be advanced.

3. Concerning the last theory of the possible power that the antiseptics administered may neutralize the toxic effects of the ptomaines produced, anything that may be said is merely a question of speculation.

It is fully recognized that these ptomaines are produced, and that they check the further progress of the germs that produce these is also appreciated, but when they are developed within the body, in many instances at least, they appear in quantities that the system falls a victim to their presence before the micro-organisms can be affected.

Insomnia and Its Treatment.

BY FRANCIS EDMUND CLAY, L. R. C. P. (LOND.), M. R. C. S. (ENG.).

Fellow of the Guthrie Society.
Honor Oak, London, England.

I know not whether insomnia should be regarded as a disease, a malady, a disorder, or merely a symptom. Nor do I know how to define it, unless it be by saying that it is a lessening or diminution in the normal amount of sleep. This, however, is not a real definition, for the number of hours of sleep needed for the maintenance of health varies in different people, and at different periods of life of the same individual. A robust, active, energetic man, in his prime, can do with very little sleep, whilst young children, and, at the other extremity, those full of years, pass the greater part of their lives in sleep, or, at all events, in a condition of somnolence.

It is probable that most of us spend nearly a third of our lives in sleep, and it

is said that sleep is more necessary than food. We have some rough idea, thanks to the exhibitions of fasting men, and, especially to those cases in which miners have been kept in forced confinement, as to how long life may be maintained without food, or, at all events, with the absolute minimum of nourishment. Many of these so-called records are open to considerable doubt and suspicion, but probably a healthy man could bear an enforced abstinence from food for four or five weeks. How long he could survive if deprived of sleep I do not know, but probably not for many days. "Deprived of rest all prematurely die." It is said that in China prisoners are sometimes tortured by keeping them awake, but I do not know that there are any authentic statistics bearing on this point. It is not uncommon to hear women say that they have had no sleep for weeks, but this is probably illusive, and snatches of sleep have been taken from time to time. The average patient who says that he has not had "a wink of sleep all night" has, probably, slept from three to four hours. His statement that he has heard the clock strike every hour during the night is true, but the clock rouses him for a moment, and he then continues to sleep again. Men, overcome with fatigue, will sleep in the standing position, and even when riding on horseback. The whole subject is full of interest, but presents many difficulties. I am inclined to say, in the words of Tristram Shandy, "I wish I could write a chapter on sleep; it is a fine subject."

There is no doubt as to the recuperative power of sleep, and this has been referred to by writers in all ages. Miguel de Cervantes, in Don Quixote, says: "Now blessings light on him that first invented sleep! It covers a man all over, thoughts and all, like a cloak; it is meat for the hungry, drink for the thirsty, heat for the cold, and cold for the hot." Edward Young, in *Night Thoughts*, speaks of it as: "Tired nature's sweet restorer, balmy sleep!" Whilst Coleridge, in the *Ancient Mariner*, says:

> "O sleep! it is a gentle thing
> Beloved from pole to pole."

Clearly, insomnia may be divided into two primary categories, (1) acute insomnia and (2) chronic sleeplessness. The acute cases are by far the most serious, and may be regarded as constituting a distinct disease. They may be the result of prolonged strain or overwork; the most typical example of this is seen in nursing a near and beloved relative. When the life of a husband or child hangs in the balance, the wife or mother will remain awake and watchful for days together. It is bad enough in acute pneumonia, where a crisis may be reasonably expected in from five to eight days, but the strain is much more severe in enteric fever, where the result is in doubt for four or five weeks, or even more. Incidentally, I may mention that I have known cases of typhoid fever where, as the result of a succession of relapses, the patient has remained in a typhoidal condition for three months. In the tuberculous meningitis of children the patient may hang on in a practically hopeless condition for weeks, or even months, until the mother is completely worn out with watching and anxiety. One of the worst cases of acute insomnia which came under my notice was that of a man whose wife was arrested for procuring goods and then pawning them, the offense being committed at his instigation.

In addition to the acute cases, it is not uncommon to come across intermittently acute cases. A friend of mine, a well-known physician, suffers from this form of the complaint. He is habitually a poor sleeper, and from time to time, without any apparent reason, gets attacks of complete insomnia, lasting for three or four days. On one occasion, during a more than usually severe attack, he went on a week-end visit to a country house. In the middle of dinner, and to the surprise of his hostess and fellow-guests, he fell fast asleep, and could not be roused. He was carried up to bed, where he slept heavily for forty-eight hours, waking up perfectly well, but unconscious of what had happened.

Cases of chronic sleeplessness, possibly alternating with attacks of drowsiness, may often be traced to some organic disease or derangement of function of some of the important viscera. In cardiac valvular mischief this condition is not infrequently met with. In the senile vascular change, associated with some forms

of Bright's disease, the patient complains that he readily drops off to sleep, but as readily awakes, and this he may do a dozen times in the course of the night. In cases of chronic constipation, especially when there is a sluggish condition of the liver, rest is often much disturbed. This is probably a toxic condition allied to the copremia, which is supposed to be a factor in the production of anemia. Speaking generally, it may be said that whatever disturbs or alters the cardiac rhythm or interferes with the blood supply to the brain and nerve centers, interferes with sleep. Another example may be found in cases of convalescence from the acute specific diseases, such as the exanthems, enteric and other continued fevers, erysipelas and, above all, influenza. Gastric and intestinal disorders, and the associated dyspeptic and flatulent conditions, are responsible for a certain proportion of cases, as are the poisons of gout and rheumatism.

It is well known that some beverages interfere with sleep, the most familiar examples being tea, coffee and cocoa. It is a common habit to take early tea in bed to dispel the last traces of sleep. We take alcohol at bed-time to woo, and tea in the morning to drive off sleep. Many people say that black coffee taken at night keeps them awake, but, on the other hand, tolerance is soon established, and after a few nights the habit may be indulged in with impunity. The custom of taking a liqueur with the post-prandial coffee probably acts in two ways (1), as an aid to digestion and (2) by counteracting the effect of the caffeine on the nerve centers. Alcohol, in the majority of cases, induces sleep, but exceptionally, and in persons who do not employ it habitually, it causes restlessness, possibly by overstimulating the heart and circulation. A similar idiosyncrasy is observed with tobacco, although nicotine, to those accustomed to its use, acts as a sedative, and may be taken with impunity in the form of a pipe or many pipes, even up to the moment of retiring to rest.

There are certain drugs which prevent sleep, and in this category must be included opium and morphine in persons who have employed them so constantly that they cease to exert their customary narcotic effects. I have known cases of persistent sleeplessness induced by coca wines, and especially by cocaine. The cocaine habit is much on the increase, and many people continue taking cocaine without realizing the harm they are doing. They probably commenced by purchasing cocaine tablets, or lozenges containing cocaine, menthol and rhatany for a relaxed sore throat, and the habit grows up imperceptibly. In every case of sleeplessness care should be taken to ascertain if the patient is taking or has recently been in the habit of taking drugs.

The late Sir William Broadbent, some years ago, pointed out that by far the most common cause of sleeplessness is gastro-intestinal derangement, especially when associated with flatulence, and while distention of any part of the alimentary canal may give rise to dreams and broken rest, or definite wakefulness, it is gastric dyspepsia which gives nightmare, and dilation of the stomach which produces the most serious and obstinate sleeplessness. He points out that, associated with the sleeplessness, there is often a degree of depression, which is not explained by the mere loss of rest, together with irritability, and a tendency to look on the dark side of affairs. One of the first things, therefore, to be done in a case of sleeplessness, he says, is to inquire carefully and thoroughly into the state of the digestion, and to make a physical examination of the abdomen. Any derangement which may be discovered must be rectified. One form of sleeplessness is so common in association with dilation of the stomach as almost to be characteristic. The patient goes to sleep at once on getting into bed, but in one, two, or three hours wakes up with remarkable punctuality; it may be quietly, without obvious discomfort, or with a start or bad dream, or actual nightmare, or with violent palpitation or pain in the region of the heart, or in profuse perspiration. He is at once particularly wide-awake, and the brain seems to be prenaturally active. If he has worries they crowd into his mind, and are set down as the cause of his wakefulness; if he has no definite troubles, he invents or goes in search of them. The explanation of the waking up at a given time is that the stomach, not having got rid of its

contents, fermentation of the stagnant matters takes place, and, after a certain time, sufficient gas and acid are produced to put an end to sleep. Sometimes a hungry, sinking feeling is experienced, and some form of nourishment is taken, after which the patient may sleep, and he attributes the waking up to exhaustion. The sleep, however, is due to the displacement of gas by the food taken, or to the dilution of acrid matters in the stomach. A dry biscuit is often more effectual than liquid nourishment. It is noteworthy that such patients make no complaint of flatulence, although the stomach resonance may be very extensive and tympanitic, and may invade the chest up to the fifth space or rib. When we are conscious of flatulence, it is not of the presence of gas, as such, but of the attempt to get rid of it, or to pass it on by peristalsis. In such cases the diet must be simplified, and the stomach must never be distended. The amount of bread and other farinaceous foods, of green vegetables, and of liquid with meals, must be restricted.

I can from personal observation confirm these remarks.

I should like, in connection with this particular phase of the subject, to call attention to a few prescriptions from the clinique of Professor Albert Robin, of the Hôpital Beaujon, of Paris, which I have found especially useful in the treatment of dyspepsia due to fermentation.

For ordinary fermentative dyspepsia, in addition to the regulation of the diet, the patient is recommended to take, after each meal, a hot aromatic bitter infusion with one of the following powders in a little water:

R	Sodii Bicarb.	1 drachm.
	Magnes. Hydrat.	1 drachm.
	Sacchar. Alb.	1½ drachms.
	Cretæ Præp.	1½ drachms.
	Ess. Anisi Vel. Menth. Pil.	15 minims.

M. Ft. pulv. 12.

When the pain and distention are very marked, the following powder may be substituted:

R	Magnes. Hydrat.	25 grains.
	Sacchar. Alb.	25 grains.
	Sodii Bicarb.	15 grains.
	Bismuth Subnit.	12 grains.
	Cretæ Præp.	12 grains.
	Codeini	1/12 grain.
	Ess. Anisi	2 minims.

M. Ft. Pulv.

For lactic acid fermentation nothing, says Robin, will be found more useful than the fluorides, which may be given as follows:

R	Ammonii Fluoridi	5 grains.
	Aq. Destill.	10 ounces.

M. Sig.: One tablespoonful to be taken twice a day at meals.

For gastric intolerance, with constant vomiting, nothing will be found more useful than the following:

R	Picrotoxin	1/12 grain.
	Alcohol pro dissolv.	q. s.
	Morph. Hydrorchlor.	1/12 grain.
	Atropinæ Sulph.	1/64 grain.
	Ergotini	15 grains.
	Aq. Laurocerasi	½ ounce.

M. Sig.: Filter after mixing. Five drops before each meal in a teaspoonful of water. Not more than twenty-five drops to be taken in the day.

It will be noted that the quantities are given in grains and not in grammes.

Attacks of insomnia may be due to causes which, at first sight, appear to be trivial. In one case, I traced it to an ill-fitting denture. The false teeth were uncomfortable, and the patient took them out at meal times. His food was imperfectly masticated and imperfectly digested, the result being much flatulence and little sleep. In another case I traced it to spongy gums—the familiar *pyorrhea alveolaris*—the mode of action of which is apparent. Some little disturbance in the well-established custom of a lifetime may be the source of the trouble. For example, an alteration in the dinner hour temporarily upsets elderly people, and interferes with the digestion. An acute attack of total abstinence in people who have been accustomed to a moderate amount of alcohol will cause irregular or fitful sleep. Nurses, who have been on night duty, find that on taking up day work they are for a time unable to sleep. The list might be prolonged almost indefinitely.

With regard to the treatment of this condition, I am not much in favor of giving drugs, although I must admit that in the acute form a hypodermic injection of morphine or, better still, of morphine and atropine, is useful. Incidentally, I may mention that the injection should be given when the patient has actually retired for the night; after its administration the order should be for "lights out" and no further conversation. But in the more chronic forms I think it a mistake to resort to hypnotics, and I believe that many of them are distinctly dangerous. The great point is to seek out and leg-

islate for the cause of the condition. For example, if caused by dyspepsia, a gentian and soda mixture, a quarter of an hour before each meal, will afford prompt relief. If there is acidity, a small dose of bicarbonate of sodium, or of salvolatile, on retiring to rest, will effect a cure. If there is much flatulence, a dose of oil of cajeput, or of pure terebene, or of tincture of capsicum, or of spirit of horseradish, is all that is necessary. If there is a condition of goutiness, a few doses of colchicum wine, or, better still, of colchicine, is indicated. Constipation should be relieved by a compound colocynth pill, and if the liver is inactive, calomel, often in large doses, is effective. I rely on these simple remedies practically to the exclusion of the hypnotics. I see no objection to a single dose of twenty grains of bromide of potassium at bedtime, for it has no untoward effects, but beyond that I will not go.

I attach much importance to hygienic measures, and am a strong advocate for open windows, especially in the country. No one can expect to sleep well unless he takes a fair amount of open-air exercise. Even elderly people should take exercise. "Rest is the sweet source of labor." The mind should be pleasantly occupied, and the patient should be advised to take up some systematic occupation, even if it be only reading. Games, such as whist, bridge and chess, keep many people awake, probably by over-stimulating their cerebral centers. I have even known people kept awake by an exciting game of billiards or pool. Pillows containing hops and other aromatic drugs are sometimes recommended, but their action is purely suggestive. Massage and electricity may suit some people, but they can never take the place of exercise.

"The ingredients of health and long life are great temperance, open air, easy labor, little care."

I freely admit that the problem is complex, and I wish especially to emphasize the fact that each case must be treated on its own individual merits. Better by far to rely on the advice of a well-informed physician, conversant with the peculiarities and idiosyncrasies of the patient than on any one remedy supposed to be applicable to all cases. It is only by attention to minute details that we can hope to win back "Life's nurse sent from heaven to create us anew, day by day."

[Written for the MEDICAL BRIEF.]

A New Operation for Retro-Uterine Displacements.

BY W. O. HENRY, M. D.,

Professor of Gynecology in the John A. Creighton Medical College; Gynecologist to St. Joseph's Hospital and Omaha General Hospital. Omaha, Neb.

The varied lines of treatment suggested for retro-uterine displacements, and particularly the numerous operations suggested for this form of trouble, prove that displacements are extremely common, and that none of the methods hitherto suggested have been wholly satisfactory. Bearing this in mind, I have been led during the past few years to plan and devise an operation that has proven very satisfactory. I have not, as yet, had any cases which were followed by pregnancy, and therefore am unable to state whether the result of the operation will interfere with normal pregnancy or not, although I see no reason why it should.

Every gynecologist knows that when the uterus is placed in proper position, even though the body be unusually heavy, it is not difficult to retain it in this position, so that any operation which will gently draw the body forward will suffice to retain it in this position without any great amount of force or traction. The operation which I have devised is based upon the fact that the uterus normally, is held in position chiefly by various ligaments, and the body inclined forward, both by the vesico-uterine and round ligaments, and perhaps, also, by its own muscular structure, and when once brought forward a very slight ligament of any kind which bends it well forward under the symphysis pubic will retain it there very nicely.

Martin's operation, which was done through the vagina, detached the bladder from the uterus, pulling the uterus downward and then sewing the bladder to the body of the uterus higher than its normal attachment. This succeeded very

well in holding the body forward, but it produced an unnatural condition, leaving a long cervix and deep anterior fornix, so that while it produced a fairly good result, there remained this unnatural condition, and the difficulty of knowing just what was in the pelvic cavity (I refer to the condition of the tubes and ovaries); and to this was added the difficulty of doing the operation through the vagina, the danger of infection and of cutting into the plexus of veins, thus interfering with good union. All of which was rather against the Martin operation.

The operation done by me I consider a good substitute for the Martin procedure. I open the abdominal cavity in the median line, bring up the uterus, break up all adhesions, do whatever plastic work is necessary on the adnexa, and then scarify the anterior surface of the uterus and posterior surface of the bladder for one-half inch or more in depth, then sew the base of the bladder and the vesico-uterine ligaments higher up on the anterior wall of the uterine body with a No. 2 catgut suture. By this method I have no new bands around which loops of intestine or omentum can become attached or produce any kind of obstruction in the abdominal viscera. We thus get an adhesion between these parts so that Nature throws out an extension, which she forms into new connective tissue; and thus following Nature's plan we have simply extended a little higher on the uterine wall the natural ligaments which hold the body of the uterus forward. After a few weeks this tissue is so thoroughly organized that the union is very firm, the patients do well after operation, exhibiting no bladder symptoms nor difficulty of any kind.

I have had some ten or twelve cases treated in this manner, and so far as I know, only one of them has had any recurrence of the displacement, and that was in an early case in which I failed to bring the uterus far enough forward to get the desired result.

I have shown this operation to a number of men who expressed themselves as strongly in favor of it. Of course, too few operations have been done, and the cases have not yet been observed sufficiently long to know what the ultimate result will be, but it seems to me that this procedure is along the line of the ideal operation for retro-uterine displacement.

Infections of Gall Bladder, with Report of Cases.

BY SHERMAN LEACH, M. D.,

Professor of Surgery and Clinical Surgery in the Starling-Ohio Medical College.
Columbus, Ohio.

The function of the gall bladder is to act as a store-house for the excess of bile which is not needed in the process of digestion. When bile is contaminated with bacteria it becomes thickened and inspissated, and soon granular masses form, around which there is deposited the various bile salts to form the so-called gall-stone. With the gall-stone once formed more traumatism is produced and more inflammation occurs. With an increase in the destructive process of the mucosa, and in case the stones are of such size that they find their way into the ducts, we have the same injury inflicted upon the mucous lining of these channels.

When an individual suffers from an attack of biliary colic it does not necessarily signify that stones are present in either the gall bladder or bile ducts. The condition may be due to a stricture or kinking of the ducts, and the colic results from a contraction of the muscular fibers of the gall bladder in its effort to overcome the obstruction. Neither is colic any longer looked upon as the most important symptom *per se* of gall-stones or an infected gall bladder; other symptoms are of greater value. A few years ago a diagnosis of gall-stones was seldom made unless the patient gave a distinct history of biliary colic, followed by marked jaundice and the finding of one or more stones in the stool. At the present time we arrive at a diagnosis by considering another set or class of symptoms, and depend upon the above mentioned as corroborative.

Considerably less than fifty per cent of all gall-stone cases give a history of colic or jaundice, but all of them give a history

of gastritis, dyspepsia, bloating of the stomach and intestines, together with tenderness over the gall bladder region. More or less pain is complained of, and usually radiates to the right shoulder or subscapular region. The point of greatest tenderness is located between the margin of the ninth costal cartilage and umbilicus, and is best elicited by directing the patient to take a full inspiration, at the end of which a sharp tap will invariably be followed by marked pain and tenderness.

My personal experience leads me to believe that the most constant symptom, and the one invariably present, is the gaseous formation in the stomach and bowel. The number of cases operated for the relief of gall-stone colic constitute a very small percentage as compared with the large number treated surgically for the relief of the gastric disturbance. In only two or three out of a dozen or more cases operated during the past two months was there a distinct history of biliary colic. There was, however, a distinct history of gastro-intestinal disturbance, and in every case pain and tenderness which varied in severity according to the amount of inflammation present about the gall bladder.

The pulse and temperature very infrequently serve as a criteria to the existence of stones or the presence of an infected gall bladder. Even in the presence of a suppurative gall bladder we frequently find no increase in the pulse rate or temperature, as is well shown in the following case history: Mrs. H., aged forty-one; weight, two hundred and seventy-five pounds; had suffered from gastric disturbances and irregular attacks of vomiting for over two years. Pain, of a vague character, was occasionally complained of over the region of the gall bladder. The patient's habits of living were most irregular, and her daily diet consisted largely of Dutch lunches, and other indigestible articles, together with beer, wine and whisky. On the twentieth of last December she had one of the usual attacks of gastritis, which was characterized by marked "bloating" of the stomach and intestines; gaseous eructations and tenderness over the right hypochondrium. Pain was complained of in the region of the appendix. At no time had the patient suffered from an attack of biliary colic, and she was never jaundiced. She was under the care of a very excellent physician, who, suspecting an infection of the gall bladder, asked me to see her in consultation, January 2, 1906. She presented the symptom-complex already given; the pulse was seventy-six, and the temperature normal. I corroborated the diagnosis of an "infected gall bladder," and advised operation, which was made January 9, 1906. On opening the abdomen I found the gall bladder surrounded by dense adhesions, filled with ten to twelve ounces of pus and a gall-stone the size of a walnut. This case, together with many others I might mention, demonstrates clearly that the usual signs of gall-stones are rarely present; also, that we may have an empyema of the gall bladder without an elevation of temperature or an increase in the pulse rate. In this case the predominating symptoms were the gastro-intestinal distention, the pain and tenderness at a point midway between the ninth costal cartilage and the umbilicus.

In another case, a woman aged seventy-one was treated by a specialist for nasal trouble. A few weeks after the nasal operation, and before the wound had healed, she developed a pain in the right hypochondriac region, an increase in the pulse rate, and a high temperature. I saw her in consultation. She had never had an attack of biliary colic, nor had she been jaundiced, but gave a history of "stomach trouble," gaseous distention of the stomach and bowels, yet persisted in saying that she was not a dyspeptic in any sense of the word. From her history of pain, the existing tenderness and swelling in the region of the gall bladder, together with the rapid pulse and temperature of 103° F., a diagnosis of suppurating gall bladder was made, and an immediate operation advised. She was operated on the following morning, when six or eight ounces of pus, and seven small stones were removed.

Another case operated a few weeks ago, gave all the usual symptoms, together with a palpable tumor. One year passed from the examination until operation. The tumor disappeared during the in-

terim, and the patient lost one hundred pounds in weight. The loss of weight, of course, suggested the possibilities of cancer. The gaseous distention was the prominent and troublesome symptom. At the time of operation twenty-six stones were removed. In another case, a woman aged forty-one, who had had several attacks of colic, but no jaundice, complained of a persistent and troublesome accumulation of gas in the stomach and bowels. She had a peculiar tinting of the skin, a complexion suggestive of nephritis, but other than this nothing that would point to gall-stones. She was operated, when extensive adhesions were dealt with, and twenty stones removed.

A case operated a short time ago had no other symptoms save the "gas sign." He had lost considerable weight, yet showed no marked cachexia. At operation the gall bladder was found filled with stones, and the seat of a well-advanced carcinoma. Another patient who left the hospital only a few days ago had experienced two or three attacks of colic, and was jaundiced after each paroxysm. The "gas sign" was ever present. An operation was made, when five stones, four in the fundus of the gall bladder and one well down in the cystic duct, were extracted.

Another case operated at a local sanitarium demonstrates to a nicety the reason why physicians so frequently overlook gall-stones owing to the prominence given to persistent stomach symptoms. The patient, a man of means, and a dentist by profession, had consulted the most able physicians of New York and other Eastern cities, as well as prominent medical men in the West. He was invariably told that he had gastritis, and was advised to take treatment at the various sanatoria and springs for its cure. He became addicted to the use of morphine during his long period of sickness, and was finally told that he was suffering from "morphine pain," and was sent to the Park View Sanitarium for its cure. He had been under treatment for ten or twelve days; the morphine had been entirely discontinued, and he was apparently progressing nicely, when, on Sunday night, he began to suffer from one of his sick attacks of "stomach trouble." Later his condition became so serious that I was called in consultation. His suffering was so intense that it was impossible to examine him, so I advised a half-grain of morphine, which was reluctantly given. I visited him early the next morning when I found him quite free from pain, and the abdominal muscles so relaxed that I was able to make a very satisfactory examination. After obtaining a detailed history, and thoroughly examining the patient, I made a diagnosis of gall-stones, and advised immediate operation, which was made on the afternoon of the same day. On opening the abdomen I found the omentum, duodenum and stomach closely adherent, and the gall bladder distended to its fullest capacity. The adhesions were freed, and the gall bladder aspirated of six ounces of viscid mucus. Six stones were removed, one of which had found lodgment in the cystic duct. From the time of the operation up to the present, he has had no use for morphine, has regained his lost weight (seventy-five pounds), and returned to the practice of his profession.

It is my wish to impress upon your minds the importance of not overlooking gall-stones simply because the patient gives no history of gall-stone colic, or of having been jaundiced at any previous time. Of far greater importance than either is the "gas sign;" then, if in addition, a history of colic or jaundice can be elicited, you may feel that your opinion of "gall bladder disease" is further corroborated. Moynihan puts it forcefully when he says "if one wishes to frame an epigram, it could be said with truth that the most common symptom of gall-stones, is indigestion."

In this connection it is interesting to note that persons may have gall-stones, and their existence during life unaccompanied by symptoms, and found only through accident, or at *post-mortem*. Personally I am of the belief that if a detailed history could be elicited, every patient (with a very few exceptions) would confess to having had, at some time, a trend of symptoms referable to the digestive tract. However, in a few cases where gall-stones have been accidentally discovered while making some other operation,

a subsequent history has failed to show any symptoms which would indicate their presence. While this is true, I thoroughly believe that in such cases all we would need to do in order to make their presence known, would be but a slight infection of the gall bladder, the impaction of a stone in the cystic or common duct, or a disturbance or disarrangement of the stones in the gall bladder. These changes will likewise explain the sudden acuteness of the symptom complex in many of the cases already diagnosed. Ehret and Stolz, in order to discover the cause of the sudden onset of the symptoms of an acute infection, in cases of cholelithiasis, fed dogs, into whose gall bladders sterilized glass balls had lain for three months, decomposing meats. An acute enteritis followed, and later a purulent cholecystitis developed. The infection was an ascending one from the duodenum, and proves that any decomposing or irritating food may not only introduce fresh organisms, but may tend to increase the activity of the ones already present.

The complications arising from the presence of stones are so numerous and so serious, that it seems to me that there is but one alternative, that is to advise an operation in every case where a diagnosis of an infected gall bladder or ducts has been made, provided no contra-indications exist for surgical intervention.

So many cases of ruptured gall bladder have been reported recently, cases in which the patients have not been previously considered ill, that I can scarcely help feeling that the physician is guilty of a grievous wrong, who, in the light of such reports, will persist in the administration of sweet oil and phosphate of soda, hoping to cure his patient, when he knows it can do nothing more than palliate. If, for any reason, surgical intervention is contra-indicated, the case should be made a medical one, and everything done to make the patient comfortable. In order to do this, we must depend upon internal drainage. Give freely of good, pure water, which will do much, possibly more than medicine, toward accomplishing the desired end. It aids in flushing the kidneys, assists in overcoming constipation, and favors the elimination of all the by-products. Next, by means of internal medication, I have found five-grain doses of succinate of soda beneficial; along with this the phosphate and olive oil if you choose.

The diet is the most important factor, and should not be overlooked. You should eliminate, as far as possible, the starchy foods and sugar, and avoid, at the same time, any over-feeding. Prevent, in every way possible, the decomposition of food products in the intestinal tract, thereby avoiding any additional bacterial invasion. Of equal import is active out-door exercise; walking, horseback riding, etc.

802 N. High Street.

[Written for the MEDICAL BRIEF.]

A Rectal Examination.

BY CHARLES J. DRUECK, M. D.,

Professor of Abdominal and Pelvic Surgery at National Medical University; Rectal Surgeon to People's Hospital; Surgeon to Lakeside and Emergency Hospitals; Member of the Chicago Medical Society. Chicago, Ill.

The object of this paper is to bring before its readers the essentials of an examination of these parts and to assist the physician in making an intelligent diagnosis of his patient's ailment, instead of trusting to luck and a "shotgun" prescription in the form of an injection or application. Many general practitioners overlook details and make a cursory examination of patients suffering from rectal disorders. I have had many such patients report to me whom the doctor had not even examined.

Before we can diagnose or intelligently treat pelvic disturbances, we must learn to inspect and palpate not only the exterior surfaces, but also explore its hollow cavities. A thorough rectal examination not only considers the coats of the last few inches of the alimentary canal, but determines the condition of all of the organs and structures within the true pelvis. In gynecology the rectal examination confirms the vaginal findings, and in diagnosing conditions in the male pelvis it is the only method of actually feeling the parts in question. We can not go into details here, but doubtless every physician has cases at present where the weight of

what has been said will be appreciated. The rest of this paper will be limited to the findings in and pertaining to the rectum; but I urge the reader to remember when exploring these parts that all the pelvic organs are bound together by one grand nerve plexus, and nowhere else in the body are there so many reflex nerve impulses. Frequently a robust man is invalided by direct or reflex disturbances, when very little pathological change can be found. The practitioner who wishes to retain the confidence of his patients must examine the rectum carefully as he would any other part of the body, for the time is past when patients will be satisfied with a placebo. All modern textbooks on surgery find it necessary to incorporate a chapter on diseases of the anus and rectum.

Rectal diseases are always progressive, and an early diagnosis may mean a slight operation, and no absence from business, while later the condition may be so exaggerated as to confine the patient to his bed for weeks or months. Almost every patient who realizes he has a rectal trouble informs his physician that he is suffering from piles, and, I am sorry to add, many doctors accept the patient's diagnosis, and prescribe without ever examining the parts.

The symptoms of rectal abnormalities sometimes draw the patient's attention at once to this particular organ, but again, because of the intimate connection of the rectum and other pelvic and abnormal organs, the symptoms may be so obscure or the onset so insidious that reflex disturbances elsewhere are first complained of, and the patient is treated for disease of some other organ. While the symptoms may refer in general to this part of the body, they do not indicate the specific disease. The odor of cancer or the pain of fissure are characteristic, but they do not in any way indicate any associated condition or disease. The preliminary interrogation of the patient should be systematic, so as to cover carefully and completely the whole case without repeating. It is a good plan to let the patient tell his own history, and for the physician to bring out the patient's age, physical condition and nervous temperament, the duration of the disease and the progress of the symptoms since their appreciation, together with whatever effect they have on the general health. If pain is complained of, ascertain its character; whether it is sharp and cutting, burning, or dull and aching, and its relation to defecation; whether it occurs before, during, or after the passage of the stool, and whether it is constant or intermittent, and its location, as at the anus, within the rectum, in the pelvis, or in the sacrum, or whether it radiates from a given point. The patient's statement that he has pain in the rectum is too indefinite to be accepted without further questioning. If there are any discharges, their nature, and the presence and amount of blood, mucus or pus, are important. If blood is present, find out whether dark or bright. The sphincters must be investigated as to whether relaxed or abnormally contracted, and if protrusions exist; whether they recede of themselves or must be replaced, and whether their replacement is difficult or painful. It is important to ascertain the character of the protrusions, as smooth or nodular, hard or soft, or covered with rugæ, and whether it is tender or sensitive to the touch, and if there are any ulcers present; also, whether it occurs only during defecation or is continuously exposed, or can be produced at will. Any evidence in the general economy of such other diseases as anemia, tuberculosis or syphilis, must be taken into consideration; also, the condition of the kidneys and bladder, and whether the patient has had gonorrhea or any urethral stricture. If a female, and married, how many children or miscarriages, and was there any rupture of the perineum? Is there any uterine or ovarian pain; any vaginal discharge; prolapse of the uterus, or difficulty in urinating? If a virgin, inquire as to the menstruation; whether regular, painful, scant or profuse.

The occupation or mode of life of the patient may not have been a factor in causing the disease, but it may be important in mapping out his future mode of living as to habits, environment and diet. Does he use enemas frequently? Or, like the proverbial Irishman, take his pipe and daily paper to the toilet with him? Does the rectum feel full after the evacuation, or is there a desire for further ac-

tion? Is there a history of sodomy or venereal disease, or any family history of tuberculosis or cancer?

The examination of any case, medical or surgical, is incomplete unless we go into the family and personal history. It is often tedious, and much time is wasted on irrelevant matter, but frequently it emphasizes idiosyncrasies. For convenience, I have arranged all the important items of the examination in an abbreviated but comprehensive form in my record sheet. I want to emphasize the importance of keeping these records in even the simpler cases. One never knows what may develop later.

It is convenient for those treating rectal cases to have a toilet adjoining the examining room, that patients may empty their bowels just before examination. When this is not practicable, and only a few rectal cases are seen, a commode which, when not in use can be screened or easily pushed aside, may be substituted. If possible, a cathartic should be given the day before, and the rectum washed out with an enema just prior to the examination. This procedure is absolutely necessary when the upper part of the rectum is to be examined, as otherwise, when the speculum is introduced, the field may be obstructed with feces, and a thorough examination is impossible; also, because the straining during defecation brings down hemorrhoids, polypi or prolapse, and thus assists in the diagnosis. Even with these precautions you occasionally find a case of impaction, where the rectum is lined with inspissated feces. Occasionally I prefer to make an examination without this preparation, that I may find the rectum more in its customary condition, and any pus, blood, mucus, or hardened feces may be found more readily. Small protrusions or prolapses often retract within the anus when the patient walks a little, hence it is sometimes necessary to examine the patient on the commode, or just after arising, before he takes a step. All constricting bands, clothing or corsets, must be removed or loosened, for they have a tendency to force the bowels into the pelvis. The bladder must also be emptied. It is often necessary to administer an anesthetic to secure a thorough examination of all parts, and to fully relax the sphincter.

Gentleness is important in making a rectal exploration, as much pain may be avoided, and spasm of the sphincter prevented. Very much also depends upon the skill of the examiner, because sometimes the ordeal may be very painful, and doubly so if carelessly performed. Few instruments are needed, and only such as every physician has in his case. In examining the upper portion of the rectum a speculum and good light are necessary. A speculum illuminated with a small electric lamp on a slender shank, clamped into position on the ordinary speculum, is the most satisfactory; but good, direct, or reflected light may be used.

In regard to the position of the patient, the exaggerated lithotomy, the Sims, and the knee-chest positions, each have their special advantages in particular instances. The ordinary dorsal or lateroprone position is all that is needed for the lower rectum, although many prefer the exaggerated lithotomy, the patient's hips being elevated by a cushion. The knee-chest is, however, the only position that permits an examination of the higher portions of the rectum or sigmoid. The Sims' position, with the thighs strongly flexed and the breast on the table, the left arm hanging over the edge, inverts the pelvis and allows the contents to fall upon the front wall of the abdomen; the lumen of the rectum tends to gap, and the mucous membrane falls away from the end of the speculum.

The examination comprises inspection, digital and instrumental examination. Inspection may reveal the conditions which produce various neurasthenic or anemic conditions. The shape of the anus is sometimes important, whether normal, protruded, or drawn in (funnel-shaped), and the amount of pigmentation about the parts. Evidences of abrasions, scratches, pediculior worms, may be seen on the skin about the anus, also signs of inflammation or scars. A prolapsed rectum may be the cause of prolonged vomiting or pertussis. An ulcer, fissure or pruritis may excite rectal tenesmus, and also produce a scybalous stool. Protruding tumors, condylomata, such as hemor-

rhoids, polypi or malignant growths, may also be seen and their characteristics noted. Very often a distinct fullness or bulging of the anus is seen where internal hemorrhoids are present, even if they do not protrude. Where epithelioma exists at or outside of the anus, a small piece may be clipped off for microscopic examination, without any discomfort to the patient, by using a little local anesthetic. After carefully inspecting the anus and perineum, the field may be widened by gently pulling the anus open, a hand being placed on each buttock, the finger tips pointing toward the anus. If the patient bears down at the same time, a considerable portion of the mucous membrane will be everted, the extent depending on the relaxation of the sphincters. In this way, the lower inch or more of the bowel may be inspected without the use of a speculum, and a fissure, fistulous opening, gonorrhea in women, syphilitic erosions, eczematous excoriations or pinworms, may be brought into view. In many instances the internal opening of a fistula is situated immediately within the external sphincter, and, in such a case, it may be seen by this procedure. During this maneuver, any tender or indurated areas may be mapped out. Fistulous tracts are easily followed up without the use of the probe. In women who have relaxed sphincters, a portion of the interior of the rectum may be everted by introducing the index finger into the vagina and pressing the rectal walls out through the anus. The presence of a discharge issuing from the anus indicates disease within the rectum; while the sunken ischiorectal fossæ and retracted anus surrounded by a profuse growth of soft hair would immediately suggest malignant disease or tuberculosis within the rectum, with general systemic involvement.

Digital examination of the interior of the rectum follows inspection, and it is the most important of all methods. The practitioner who is familiar with the digital examination of these parts can diagnose better with his finger than by any other way. Fully eighty per cent of all rectal cases may be diagnosed with the finger, and the other twenty per cent by the history of the case and a specular examination. Digital examination not only confirms the opinion regarding the local conditions found by inspection, but also determines other conditions to which the attention may have been directed. The finger should first be swept around outside of the anus to palpate any induration or tenderness, either superficial or deep, which might indicate abscess or fistula. For internal examination the finger-nail should be well-trimmed, and the finger anointed with olive oil, which is not so easily rubbed off as is soap or vaseline by the sphincter. Whatever lubricant is used must be kept in collapsible tubes, as this is the only method of having clean, sterile lubricant at all times. The cost is little, and the advantages great over the old-fashioned jar of vaseline into which the fingers and instruments were repeatedly dipped, carrying infection from one patient to another. For esthetic reasons, the rubber tissue cot may be worn if desired, because it will not affect the sensibility of touch, and may be washed and anointed. The finger is then gently insinuated through the anus with a rotary or boring motion, the patient being asked to bear down at the same time, and the rectum systematically palpated as high as the finger will reach. The introduction will be rendered much easier if the normal direction of the rectum is remembered, and the finger is first directed up and forward toward the neck of the bladder, until the sphincter is passed, and then backward toward the sacrum. The sphincter is very sensitive, and any undue haste or roughness may induce spasm of that muscle, which will make the examination very painful and unsatisfactory. The iliac fossæ should be firmly explored to determine whether there is any tenderness or tumor. The finger should be introduced its full length, and, by passing the other fingers of the hand back into the intergluteal space instead of doubling them into the palm, an increased reach is obtained; also, if the patient bears down or strains during the examination, one or two inches more of the rectum can be examined.

The condition of the sphincter should be noted; whether it is relaxed, suggesting a debilitated system, cancer, or large internal hemorrhoids, which latter

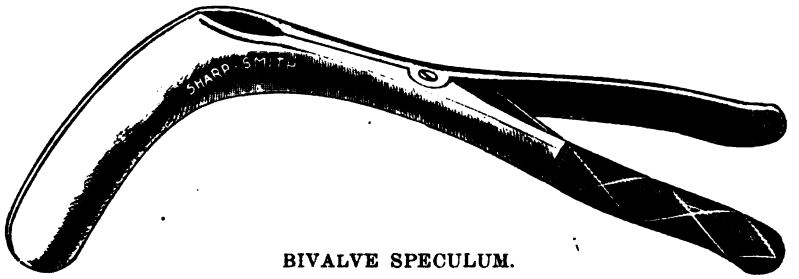
weaken the muscle by frequently protruding; or contracted, signifying acute disease in the anal canal, anal fissure, or a nervous subject; or whether hypertrophied, denoting chronic disease; or, finally, is it atrophied? The spasmodic action should be overcome by slow, steady pressure, as the sphincter is always forcibly contracted on attempting examination. Frequently the internal opening of a fistula is found just within the sphincter, as a rough, indurated and sensitive spot which may be elevated or depressed (ulcerated); or the path of the sinus is felt by its cord-like resistance. If the tumor is felt, its size, shape, location, movability and resistance are to be ascertained, and, if possible, a small piece removed later through the speculum for microscopic examination. Fecal impaction of the rectum or colon has often been mistaken for cancer, polypi, stricture, abscesses; gallstones and other foreign bodies are occasionally felt. The tumor of appendicitis is found in the right pelvis if the appendix is low, and rectal palpation should be practiced in every case of suspected appendicitis. Malignant disease of the rectum or pelvis, the tumor of intussusception or an infected lymph gland may also be felt. Induration or constriction of the walls and the condition of the other pelvic organs is to be determined. Palpation of the prostate may reveal enlargement, induration, tenderness or soft points. The uterus and appendages should always be examined. Vesical irritation is a frequent source of reflex disturbance, and the bladder always should be examined. A stone may be found to be the origin of the trouble, although no symptoms were manifested. A digital examination through the rectum often assists considerably in diagnosing diseases of the urethra, Cowper's glands, seminal vesicles, bladder, vagina and pelvic bones; also, tumors and abscesses of the peritoneal cavity, dislocation of the femur, ischial hernia and aneurysms of the gluteal artery. Very little information is gained by digital examination regarding hemorrhoids, except in rare cases, where much hypertrophy has occurred in the mucous membrane. Otherwise, the hemorrhoid being covered with nearly normal mucous membrane, gives no differential tactile sensation. Thus you see a digital examination through the rectum is imperative in any case indicating disease below the pelvic brim. On withdrawing the finger it may be covered or streaked with blood, pus or mucus, each with its own significance. If a stricture is so small as not to admit the passage of the finger, no force should be used, as rupture of the bowel has followed such an attempt. The cervix, the fundus of the uterus, or the prostate may be mistaken for a tumor. In rare instances it may be necessary to introduce the whole hand into the rectum, but as the walls are so crowded upon the fingers, and the folds of mucous membrane fall in between the fingers, very little knowledge is obtained, and there is always the danger of rupturing the bowel. A laparotomy and intra-abdominal palpation is preferable when the disease is high in the rectum or in the sigmoid. A digital examination carefully performed, is not painful unless a fissure is present.

WALES' BOUGIE.

Instrumental examination—Bougies.—That part of the rectum beyond the reach of the finger may be examined by means of bougies or sounds, although their use is open to criticism, and is often contraindicated. Only soft, flexible rubber instruments should be used (Wales' bougies), and these must be handled with great caution. They should be hollow, to permit the injection of fluid through them into the part beyond, thus dilating the rectum in advance, and effacing any folds that might obstruct their introduction.

Too great value must not be placed on bougies, as their field of usefulness is limited, and even in a healthy bowel the sensations of obstruction often are obtained, and may be misleading. I have yet to see a student who did not find a stricture

the first time he introduced a bougie, because the sound often impinges on the wall of the bowel between the fold of the gut, and a stricture is erroneously diagnosed; or it may strike the uterus or prostate, or the promontory of the sacrum. There is always danger of a metal or hard-rubber sound penetrating the bowel, especially in cancer or ulcerations. Sometimes the so-called third sphincter, which is only a semi-lunar, transverse fold of the anterior and right sides of the rectum, about six to eight centimeters above the anus, may catch the bougie. Normally the bougie may be introduced with care to the middle of the sigmoid flexure. If the mesocolon of the sigmoid is very long, the bougie may be felt on the right side, and lead the examiner to think it had perforated the bowel.

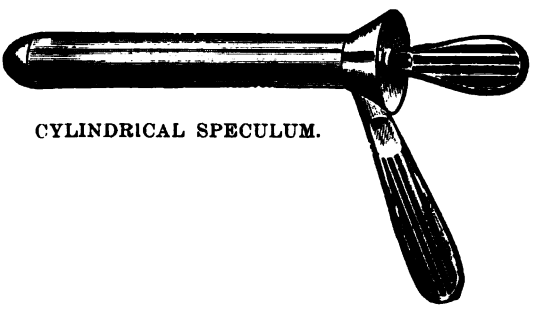


BIVALVE SPECULUM.

Probes.—The probe has no place in the diagnostics of rectal diseases, and very little in the treatment, except in fistula. Even here its value is very limited. Irrigation and injections are sometimes used for diagnostic purposes, and are best accomplished in the knee-chest or dorsal position.

Specula.—The speculum corroborates the digital findings, and aids in the diagnosis where the finger fails, but by no means supersedes the latter. It is indicated where obscure hemorrhage, pain or discharge is an important symptom. The internal openings of fistula may be seen, especially if the discharge escapes during instrumentation. Internal hemorrhoids usually drop into the instrument, and are easily seen. The decision as to which is the best speculum depends upon which one you are more familiar with. Each instrument is constructed differently, but the more rectal examinations you make the less you will use the speculum. The smooth blade bivalve causes much less pain than the wire blades, but it obstructs the field of vision, and exposes only a small area at one time, and the speculum must, therefore, be rotated.

The cylindrical speculum permits of the most thorough work. With the patient in the knee-chest position and a speculum five inches long and one inch in diameter, the whole length of the rectum may be examined. Such a speculum is provided with an obturator to facilitate its introduction, which should be accomplished without much pain. When the obturator is withdrawn, the air rushes in and dilates the bowel, and the whole rectal wall may be inspected by moving the introduced end about, at the same time



CYLINDRICAL SPECULUM.

gradually withdrawing the speculum. The mucous membrane directly in front of the speculum is flattened out and viewed easily by gently pushing the speculum up after the obturator has been removed. By putting the patient under the influence of a general anesthetic, many of the obstacles to the examination are removed, and the field may be explored thoroughly; the sphincter completely relaxes, pain is obviated, but in such cases it is well to be prepared to do any necessary surgical treatment in order to avoid a second anesthetic. When the patient is anesthetized an ordinary flat retractor frequently makes a very satisfactory speculum. A cylindrical speculum ten to thirteen inches long, may be introduced, and the sigmoid explored, but as the great majority of rectal troubles are near the anus, a short and wide speculum is preferable.

When a patient is in the knee-chest position, the chest should be well down on the table, and all constrictions at the waist must be removed.

In many instances, owing to local disease or reflex nervous excitement, we find the sphincter abnormally contracted, making an examination very painful, and often impossible without some previous preparation.

599 East Forty-Sixth Street.

[Written for the MEDICAL BRIEF.]

Pharyngeal Adenoids as a Cause of Middle Ear Disease—Operation Without General Anesthesia.

BY W. H. SCHUTZ, M. D.,

Instructor of Operative Ophthalmology and Otology in the Medical Department of the University of Kansas; Chief of the Eye and Ear Department of the Bethany Hospital; Formerly Professor of Eye and Ear Diseases in the College of Physicians and Surgeons; Member of the American Medical Association, Missouri State and Jackson County Medical Societies. Kansas City, Mo.

Symphoid hypertrophy in the vault of the pharynx causes not only aural affections, but is productive of harm in several directions, such as general lack of development of the physical economy through insufficient aerization or oxidization of the blood; naso-pharyngeal catarrh; nervous reflex phenomena; systemic infection, etc., but the purpose of this paper is to deal exclusively with lymphoid vegetations as a cause of ear disease, and especially to call attention to the so-called modified method of their removal without a general anesthetic. Before entering into the subject in detail let us refresh our memory by throwing a side-light on the anatomy and physiology of the pharyngeal vault and glands. The vault of the pharynx is a dome-shaped structure located in the uppermost part of the respiratory tract. It is continuous anteriorly with the nasal fossæ, below with the oropharynx, and latterly by the Eustachian tube, communicating with the middle ears. The bony walls consist of the body of the sphenoid and basilar process of the occipital bone on top. Posteriorly the first cervical vertebra and laterally are the internal pterygoid plates of the sphenoid and petrous portion of the temporal bones. Anteriorly the posterior bony margins of anterior nasal cavities. The mucous membrane of the space is continuous with the nasal cavities, the oropharynx, Eustachian tubes and middle ears. The arterial supply of the pharynx is derived from the external carotid branches of the ascending pharyngeal supplying the greater part of the region. The anterior portion receives terminal branches of the ascending palatine and spheno-palatine from the internal maxillary. The nerve supply is derived largely from the branches of the second division of the fifth nerve, and also branches from the glosso-pharyngeal and spinal accessory nerve. In the posterior wall of the naso-pharynx is situated a structure known as the third tonsil of Luschka, which is composed of lymphatic or adenoid tissue. It is not strictly a racemose gland. The mucous membrane covering these glands is thin, and covered with one layer of columnar epithelium. The structure contains numerous follicles, and is highly vascular. It is a physiological structure, is normally found in children, and should undergo atrophy from the twelfth to the twenty-fifth year of life. When this tissue involves the Eustachian tube, it is known as the tubal tonsil. Whether the enlargement of these glands occurs in utero, or soon after

birth, or after adolescence, it matters little, as the essential condition demanding relief is removal of the obstruction. The relation of adenoid vegetation to midde ear disease is undisputed, and I believe is unquestionably responsible for more than half of the pathological changes in the tympanum. On the other hand, in ninety per cent of the cases of adenoid vegetation there is inflammatory involvement of the middle ear to a lesser or greater degree. The effect on the sense of hearing depends upon the amount, location, duration and continuance of the obstruction. The manner in which these growths affect the ears is not by direct mechanical obstruction of the Eustachian tube, but indirectly by pressure, thereby interfering with the ventilation of the tympanum and with the local circulation, causing a venous congestion, chronic hyperemia and hyperplasia of the mucous membrane lining the Eustachian tube and middle ear, and fostering a general catarrhal inflammation of all the membranes of neighboring cavities. If under these circumstances infection should occur, it may lead to chronic suppurative conditions involving the middle ear with possible destruction of its vital parts, ending in partial or total loss of hearing. There is another class of cases of ear trouble not dependent upon hypertrophy of lymphoid tissue, but upon acute or chronic inflammation of these glands with little or no enlargement. This affection is a frequent cause of otitis media catarrhalis in children. In these cases we find very little adenoid vegetations in the vault, and no obstruction in the act of respiration. In case of an acute inflammation the parts will appear a little redder than normal, covered more or less with thick, tenacious muco-pus varying in color from a greenish white to a greenish yellow. During such attack the middle ear may be involved, producing a subacute inflammation. An external examination will reveal a congested, and probably more or less bulging, membranæ tympani. In the chronic form of the inflammation the membrane covering the pharyngeal vault may be uniformly thickened, except in the regions of the Eustachian orifices, where it is thrown into folds and reduplications, and there may be a few lymphatic nodules irregularly distributed, but no marked hypertrophy of the tissue. The symptoms dependent upon the pressure of adenoids in the naso-pharyngeal spaces are too well known to be enumerated, and so I will pass on to the aural symptoms, which are quite as characteristic as those referable to the post nares. Frequent attacks of earache, tubo-tympanic congestion and hyperemia, and possibly some rise in the temperature. In some instances the membrane will show a slight rupture and some serous discharge, and, again, may terminate in an acute suppurative otitis media. The disturbance of function is sometimes the only feature which attracts attention. Absent-mindedness, listlessness and inattention may be the only complaint, and in these cases you will elicit a history of frequent colds in the head, discharge from the nose, snoring at night, dry, crusted lips, coated tongue, etc., and if patient is old enough, complains of a full or stuffy feeling in the ears in addition to impaired hearing. The pressure of adenoids has a continuous degenerating influence on the ears of the young, and if not removed before adolescence, is prone to produce active and permanent injury in adult life. It is a disputed question to what extent the naso-pharyngeal hypertrophic tissue has been productive of aural lesions. Professor Dench, of New York, is of the opinion that the middle ear changes have resulted from the presence of an excessive amount of adenoid tissue in the pharyngeal vault at an early period of life, and does not depend upon the sclerotic changes which have subsequently taken place in the tissue, although they are similar in character.

The points of differential symptomatology between children and adults suffering with ear affection dependent upon adenoids, is that in the latter reflex phenomena of a neurasthenic type are common. Stubborn cough, with expectoration, bronchial irritation, susceptibility to colds in the head, associated with aggravated aural symptoms, such as shooting pains from throat to ear, tinnitus, vertigo and impaired hearing. There is no doubt in my mind that the cause of many cases of deaf or partially deaf subjects now going the rounds asking relief, can be

directly traced to pharyngeal adenoids in childhood. From the observations of some of our ablest investigators it seems deaf-mutism is frequently dependent upon adenoids. Cases are recorded where hearing was partially restored after removal of these growths. Dr. Frankenburg, in an examination of one hundred and fifty-eight inmates of a deaf-mute institution of Prague, found fifty-eight and one-half per cent had adenoids large enough to fill the naso-pharyngeal space. Of ninety-four persons, fifty-six were boys and thirty-eight girls. Anomalies of the ear were found in fifty-eight cases, and forty of these were pathological modifications, more or less important, due chiefly to chronic and suppurative inflammation. Of these forty-two individuals, thirty-seven presented adenoid vegetations. In an examination of twenty-six deaf-mutes, Dr. A. F. Haight, of Chicago, found only four free from post-nasal adenoids. Aside from heredity, consanguinity, traumatism and acute infectious diseases, adenoid growths is the next in frequency as an etiological factor in the production of total loss of audition. When adenoids are sufficiently extensive to cause profound impairment of hearing in early life, the conductive and receiving apparatus is affected in such a manner as to lead to deaf-mutism. Even in children three to four years of age, who speak fairly well, the loss of audition is often followed by mutism. In older children not necessarily so.

I think we all agree that the prognosis of aural affection dependent upon the presence of lymphatic growths in the naso-pharyngeal vault is unfavorable, unless the enlargement is slight or moderate, and there is no history of past trouble of serious import, and no positive symptoms of present trouble with that as a cause, there is no demand for immediate operative interference. When the hearing is impaired we should not wait for the probable spontaneous subsidence of the growth and aural affection, but operation should always be done at once.

The question now arises: Should one operate with or without a general anesthetic, and if the former, during primary or profound anesthesia? With all due reverence and respect to the skilled operators of vast experience along this line of work who insist that it is barbarous and altogether impossible to do a complete and satisfactory operation, except under general anesthesia, and to those of my colleages who advocate operation under primary anesthesia, I desire to go on record as directly opposed to their teaching, and to the contrary, practice the modified operation without a general anesthetic, with but few exceptions. The text-books almost without exception advocate the use of chloroform in this operation. Of all anesthetics chloroform is the most dangerous to administer to children suffering from adenoids, on account of the so-called "lymphatic diathesis." The presence of hypertrophied lymphoid tissue in the naso-pharynx is often but a local expression of a general dyscrasia. Occurring during the developing period of life these growths, by obstructing the act of respiration, impair the oxygenation of the blood, and by necessity to a greater or less degree, affect every tissue, every organ of the body, not only the neighboring parts, but the more remote, such as the heart, lungs, kidneys, etc. These patients, then, are in a depressed state of general health, and it has been the observation of some of our most patient investigators to find co-existing with this lymphatic habit, weak heart, impoverished blood, impaired lungs, and little reserve force to resist disease and shock.

Time and clinical experience have proven to me that it is exceedingly difficult under any form of operation to make sure that all the growth is removed, and I doubt if it is possible to remove every vestige of lymphoid tissue, owing to the irregular formation of the vault, and the fact that one is obliged to work in the dark, success in removing the growth depending upon touch rather than sight. The various methods proposed for this operation are well known to the profession. In my hands the following has been most satisfactory: In the soft variety of adenoids in young children, I resort to the compression or crushing method of the diseased tissue. Consequent on these maneuvers, repeated more or less frequently, the tissues become less inflamed, the remnants of tissue are reabsorbed, the function of the glandular tissue is

re-established as well as the circulation in the blood vessels and lymphatics. The ease with which this soft variety of adenoids may be broken up and expelled by the finger wrapped with gauze, is well known, yet there are many operators who persist in doing a so-called radical operation with cutting and curetting instruments. In older children, where the adenoid tissue is principally confined to the fossæ of Rosenmuller and on the lateral walls of the naso-pharynx, I prefer digital manipulation, and regard the operation outside the domain of cutting and curetting instruments on account of the unavoidable danger of injuring vital parts. I never use a general anesthetic in these cases. In the hard or hypertrophic variety there is an increase in the lymphatic structure, with a decided overgrowth in the connective tissue element, making the tumefaction fibrous in its consistency. In these cases, on account of the toughness of the tissue, it is absolutely necessary to employ some kind of a cutting instrument, forceps, curette or rongeur. I use curette only in isolated cases, where the mass is in median line of vault. It is the exception, not the rule, to remove the adenoids in their entirety the first operation; usually I require from one to three sittings, depending upon the amount present and the nervous disposition of the patient to complete the operation. I am in the habit of employing a local anesthetic to the field of operation.

The points worthy of consideration in this method of operating without a general anesthesia are: the little danger of fatality during the operation, the facility with which the work can be performed in the upright position, the abundant time at the operator's disposal, no danger of asphyxiation from blood clot in the trachea, and in case of unusual hemorrhage you have the assistance of the patient, and can stop operating and devote your attention to the bleeding before serious consequences ensue.

I have seen surgeons operate under general anesthesia for adenoids, with the handle of a Goldstein curette grasped in their hand, in the manner in which a stonemason holds his chisel, and scrape in the vault as if he were endeavoring to empty the contents of the subject's cranium through the naso-pharyngeal space, seemingly oblivious of the close proximity of the brain, the spinal cord and accessory cavities, with such brutal force and dangerous haste that I stood amazed —breathless, expecting every moment to see the unfortunate succumb. In the hands of a reckless, hasty surgeon this operation is the most barbarous in the domain of surgery.

The after-treatment I consider an important factor. The parts should be free from the accumulations of secretions, and kept in an aseptic state by frequent spraying. Astringents may be applied with benefit. The general system should be built up by the internal administration of iron, a point few operators consider, and another point upon which I lay special stress is breathing exercises through the nose, with the mouth closed. This should be instituted at once, and carried on systematically for an indefinite period. The patient should be kept under observation, indefinitely, on account of the possibility of a return of the trouble.

Now, as to the auditory results following the removal of post-nasal adenoids. The hearing is found, within a few days, occasionally a few hours, after operation, to be improving, and it continues to improve, as a rule, without any special attention to the ears, and the ultimate result is normal sense of hearing. There are cases in which the final degree of improvement from the operation may not be the best obtainable. What is the cause of this? Is it not possible that it may not be due to what the radical operators regard as an essential of the operation, viz., the thorough removal of the lymphoid tissue? Is it probable that the raw surface left by the too complete operation may leave an area of cicatricial tissue, and adhesive bands between the posterior wall of the pharynx and the Eustachian tubes, causing this degree of impaired hearing? Dr. D. McKeown, in his excellent thesis on this subject, says: "The chief reason for thoroughness has been the desire to avoid the possibility of a return of the adenoids; but may the fear of this tissue not be a groundless one? Presence of lymphoid tissue in the naso-pharynx is the normal condition, and after operation various circumstances are

against reproduction. 1. The devascularization of the naso-pharynx and its neighborhood. 2. The establishment by the physiological channel. 3. The development of the region involved. 4. The antagonistic influence of time on lymphoid structures. 5. The improved general health following operation.

Impairment of hearing from a reproduction of the adenoids is remediable, but impairment of hearing from faulty cicatrization is practically irremediable.

Fortunately, in the majority of cases, the hearing improves immediately after operation unless some previous pathological condition of the middle ears existed long before operative interference. In these cases longer time is required to bring about a satisfactory condition after operation has been performed.

A Case of Congenital Subluxation of the Knee Joint.

BY NORMAN DREISBACH, M. D.,
Professor of Anatomy and Surgical Anatomy in the Medical Department of Hamline University.
Minneapolis, Minn.

While cases of subluxation of knee-joint are not so rare, yet they are not commonly seen, as a search of the medical literature demonstrates. This condition, a backward displacement of the knee, can not be called a dislocation, since it is, in all probability, of congenital origin, and is doubtless caused by the position of the infant in utero. Statistics show that with proper care, the condition yields promptly and successfully, and permanent deformity is very rare in these cases.

About ten days ago I was called to attend an obstetric case, but before I reached the house parturition had occurred. I found the patient, a multipara, in good condition; the labor was completed, and the placenta had been removed by her mother, who was a midwife. I was informed that the day previously the bag of waters had broken, but that there had been no pain during parturition, although all the previous labors had been very severe, requiring instrumental assistance.

After examining the mother and finding everything all right, I directed my attention to the baby, and was shown by the anxious midwife, the grandmother of the child, that one knee was bent in the wrong direction. On examination, I found a subluxation of the congenital type, slight traction with one hand on the thigh and on the tibial portion of the leg sufficed to reduce the dislocation. On relinquishing hold, however, it immediately resumed its former condition. An improvised splint fashioned from pasteboard, padded with cotton, was employed, and removed after twenty-four hours, and a plaster cast substituted. At the present time the little fellow seems to be progressing satisfactorily. In all other respects the child was apparently normal. The circulation was very poor in that leg at first, due, probably, to the pressure of the proximal end of the tibia upon the popliteal vessels; after reduction of the dislocation the color of the foot changed from dark purple to the normal pinkish hue in a short time.

Hypodermic Syringes.

BY F. H. LONGLEY, M. D.,
North Platte, Neb.

Hypodermic syringes, as near as I can learn, were first used in Paris in 1855. November, 1866, I bought one of Otto & Reynders, M. F. G., in Cincinnati, Ohio. They were in common use with the advanced and up-to-date physicians and surgeons in the winter of 1866-7 in Cincinnati. I brought mine to Omaha March 1, 1867. You will note the hypodermic syringe made its debut coeval with the birth of our State, and I claim to be the first physician that used a hypodermic syringe in that State. I find I have the wrecks of three syringes. Some ten or twelve years since I bought a hypodermic syringe, aluminum case No. 3, of Parke, Davis & Co. Am still using it with satisfaction to all concerned, and hope to be able to use the "Opsonin" or the bacterial vaccine protoplasm serum soon.

County Sanitarium for Treatment of Pulmonary Tuberculosis.

BY R. C. MOORE, M. D.,

Professor of Diseases of the Mind in the College of Medicine of the University of Nebraska. Omaha, Neb.

Up to a comparatively recent time the treatment and management of cases of pulmonary tuberculosis have been almost invariably unsatisfactory. Of course, some cases recover without any treatment whatever, as has been demonstrated at *post-mortem* examinations by the finding of cicatrices indicating that abscesses had been present and healed over in the lungs. But since the inauguration of the sanitarium method of treatment the percentage of cures has been greatly augmented. When cases reached the sanitarium in the incipient stage from seventy to seventy-five per cent of recoveries has been reported, while the remaining cases have been greatly benefited. And even when the patient can not remain long enough to be cured, he is at least taught how to take care of himself and to avoid exposing to infection those with whom he is brought in contact.

While theoretically the sanitarium treatment could be followed out at the home of the patient, practically it is impossible. Tubercular patients must absolutely live out of doors in the fresh air, and sanitarium buildings and tents are constructed with this consideration in mind. There is such a feeling among the laity against the exposure of these patients to the inclemency of weather that on the first approach of storm or wind, the windows are closed, and the patients shut up indoors in short order, while in the sanitarium, in spite of storms, the windows are left open. During the winter season one can read in a little journal devoted to sanitarium life out of doors items like the following: "On the morning following a severe snowstorm, workmen had to reach the Rutland wards at five A. M., in order to shovel out the snow." It is impossible, practically, to convince the laity that such exposure was other than detrimental to the patient.

In addition to the foregoing great advantage, the routine life is next in importance as a feature of the sanitarium treatment. The discipline in a well-conducted sanitarium is as strict as that of a military camp. These cases are under the constant surveillance of a competent physician, and every day they are examined, the sputum is examined, there are bacteriological examinations and thorough disinfection of the discharges from the diseased surfaces, and the discharges thoroughly destroyed. Under this care, there is really less danger from infection in a sanitarium than in the streets of our cities.

In those States where the sanitarium method has not been adopted, and where the extra expense is a deterrent factor, there is an inexpensive and practical way of arranging for the care of these patients in connection with the local county hospital.

Some time ago I devised a plan for use in our local hospital, and described same before a meeting of the Medical Society of the Missouri Valley, in September, 1906. And for the benefit of those individuals or committees in counties of this or other States, who may be contemplating the erection of a sanitarium *in the future*, I suggest a careful consideration of this plan, which can be put in operation *now* at such a trifling expense as an annex to the county hospital.

Drawings for this structure were made by Mr. Kimball of this city, an architect who has given special attention to the modern treatment of tuberculosis, and who will be glad to answer any questions regarding this plan.

The structure above referred to may be modified to meet varied conditions. It should be built in easy communication with the kitchen, lighting and heating plants of the hospital. The sides, to the height of four feet, can be constructed of canvas, stucco or brick; from the top of the wall the space of three feet to the plate is covered by wire fly-screen, which, in very stormy weather, can be protected by heavy canvas curtains. The ceiling of the ward is made of wire-screen, and all openings are screened against insects. The heating will be by means of small steam coils placed under each bed, or in

other parts of the ward. The wards are designed for ten patients each, and are separated by the central building, which is divided into suitable toilet, sitting and dining rooms.

Where a less expensive structure than the foregoing is desired, the best substitute is found in the octagonal tent, designed and used by Dr. J. E. White of Colorado Springs. Being octagonal in shape with a high slanting roof (on the principle of an Indian tepee), it stands the storms extremely well. It is built of canvas, but has lately been improved by making the roof of wood. Ventilation is secured by means of an opening at the apex.

Congenital Club Foot.

BY GEORGE B. PACKARD, M. D.,

Professor of Orthopedic Surgery in the Denver and Gross Medical College.
Denver, Colo.

When shall we begin treatment in cases of congenital club-foot? While authorities differ somewhat in regard to the time tenotomy should be performed, they are quite unanimous in the opinion that other methods of treatment should be commenced in all cases within a few weeks after birth. When circumstances permit, I usually begin treatment in ten days after birth. Since the object of treatment is to correct the deformity and to retain the foot in its corrected position for a sufficient length of time to preclude the possibility of a relapse, the question of methods is an important one.

I wish to emphasize the great advantage of dividing the operation for overcoming the deformity into two steps, viz., correction of the varus and correction of the equinus. If this method of procedure is adopted, there can be no doubt of the advantage of leaving the tendon-Achilles to steady the heel and act as a counterforce in overcoming the resisting fascia and ligament of the inner side of the foot until the varus is completely overcome, or even converted into a valgus. There is a temptation to attack the equinus before the varus is relieved, and even to attempt the reduction of the two deformities at the same time, with the general result that resistance at the inner side of the foot is not overcome, and we are deceived in regard to flexion of the foot, and the tendency to relapse is greatly increased.

As a rule in these early cases I find the varus can be relieved by mechanical methods alone; but in some cases it may be necessary to divide the plantar fascia, the tendons of the tibialis anticus and posticus, and possibly the astragalo-scaphoid and calcaneo-cuboid ligaments.

One of the simplest and best methods of correcting varus is the repeated application of plaster of paris. Under anesthesia, the foot is grasped firmly, and the varus overcome as much as possible without interfering with the circulation. The plaster of paris sets so quickly that it is necessary to hold the foot in position for only a few minutes. The plaster should extend above the knee, the latter slightly bent to hold it more firmly, and prevent the foot from rolling in the cast. After ten days the cast is removed, and another plaster applied in the same way after the foot has been forced into a still more correct position. Three or four applications are generally sufficient to overcome the varus.

This method every physician has at his command, and no great skill is required in carrying it out.

Another very satisfactory procedure for relieving this part of the deformity is the application of a simple steel support which acts as a lever to throw the foot into position. It can also be worn to retain the foot in position after correction.

A brace I have used with much satisfaction, both in overcoming the varus and as a retention apparatus, is a modification of the Taylor shoe, consisting of a flat steel plate corresponding to the shape of the foot, and at right angles to this rises an inner border, to which is attached an upright, allowing forward motion at the ankle joint. A little higher there is another point allowing lateral motion, which is regulated by a strap attached to the outer border of the foot-plate, and extending to the band which encircles the leg below the knee. After the foot has been properly strapped to the foot-plate,

and the upper end of the upright fastened to the leg above the knee, the outer border of the foot can be raised to any degree by tightening the strap which extends from the foot-plate to the band. As the tissues relax on the inner side of the foot, this strap should be shortened. This constant stretching will soon correct the lateral deformity. This apparatus is simple, and can be made by any instrument maker, and is easily applied. It may be more satisfactory in some cases than the plaster of paris.

The first step of the operation being thoroughly accomplished, the next step is to bring down the heel or to overcome the equinus. In many cases we shall find that the tendo-Achilles has yielded a great deal while correcting the lateral deformity, and it only requires a little more extension by the means already alluded to, in order to complete the operation. If much resistance is offered, it is better to divide the tendon subcutaneously and bring the foot into position at once.

As before stated, there is great danger of relapse in these cases, consequently the after-treatment is very important.

The foot should be held in its corrected position for a sufficient length of time for new facets to form on the bones in their new positions, and become normal. The retention apparatus for maintaining the foot in this position should be worn day and night, and should permit of motion at the ankle joint.

Massage and electricity are useful means of developing the muscles after the deformity has been corrected.

In these cases little time would be gained by performing tenotomy before mechanical treatment has been resorted to, and the disadvantages are apparent. It will be necessary for a child to wear a retaining support for a long time in all events, and if it acts partly as a correcting force we are not consuming any extra time by this apparently slow method.

It is an error to suppose that tenotomy alone will cure club-foot in a few weeks. Cases that are supposed to be cured in this way without additional mechanical treatment being carried out, invariably relapse. I believe, therefore, that a judicious combination of the operative and mechanical treatment is generally preferable.

To sum up: I would say, begin treatment as soon after birth as possible.

Thoroughly overcome the varus before attacking the equinus.

Retain the foot in its corrected position both day and night (without interfering with the normal functions of the foot) for a sufficient length of time to prevent a relapse.

Some Interesting Medical and Vital Statistics.

BY SAMUEL F. BROTHERS, PH. G., M. D.,
Member of the American Medico-Pharmaceutical League.
Brooklyn, N. Y.

F. T. Andrews[1] (Practical Medical Series, March, 1904) examined the bacteriologic reports of 680 cases of pyosalpinx taken from the literature, and found the following percentages of organisms in his statistics of the etiology of salpingitis:

Sterile, 55 per cent.

Only saprophytes, 6 per cent.

Gonococcus, 22½ per cent.

Staphylococcus and streptococcus, 12 per cent.

Pneumococcus, 2 per cent.

Bacillus coli communis, 2½ per cent.

In 4,470 abdominal sections, tuberculosis of the Fallopian tubes was found 53 times, or in about 1.5 per cent. In 906 reported operations for inflamed uterine adnexa, tuberculosis was found in 4.4 per cent.

Statistics of the Effects of Cervical Repair.—D. H. Craig[2] cites the results in 100 cases of trachelorrhaphy, in which he was able to get replies from the patients.

Eighty-nine per cent complete cure, or great relief from symptoms.

Forty-nine per cent of child-bearing women had future pregnancies.

Out of 16 answers from the accoucheurs in these cases, 14 stated that dilatation of the cervix was very easy. Relaceration occurred in eight cases, but did not occur in seven cases. The percentage of permanently cured cases was 84.

Answers of other specialists put together with his own experience, convinced

Craig that 90 per cent of the cases of cervical carcinoma occur in previously lacerated cervices remaining unrepaired.

Vital statistics of various countries:

The vital statistics of Italy for 1899,[3] published by the Department of Agriculture, Industry and Commerce, for the year 1899:

Population, 31,762,328.

Marriages, 235,665.

Marriage-rate, 7.42 per thousand (couples).

Births, 1,088,558.

Deaths, 703,393.

Death-rate, 22.15 per thousand.

Excess of births over deaths, 385,165.

The greatest number of marriages were celebrated in February and November, and the least in July and August. The highest birth-rate was found in Puglie and Calabrie (38.1 and 39.2), and the lowest in Liguria and Piedmont (28.5 and 29.2). The greatest number of births occurred in February and May, and the least in September and October.

The sexes were in the ratio of 1,000 females to 1,063 males.

The ratio of illegitimate births was 6.14 per cent.

Of multiple births, the ratio of twins in 15,945,243 births—which occurred in 14 years, 1886-1899—was one in 87 births.

Of triplets, one in 6,914 births.

Of quadruplets, one in 759,297 births.

The highest death-rates in 1899 (25.43 and 25.39) occurred in Sardinia and Puglie, and the lowest (19.2 and 19.5) in Venice and Piedmont. The greatest number of deaths occurred in March and December, and the fewest in September and October.

The deaths of infants under one year were 168,244, or 23.9 per cent of the total mortality, as compared with 26.1 per cent for the years 1890-1898.

Vital Statistics of the Jews.—Fishberg[4] concludes that the death-rates of the Jews, at all ages, are relatively and absolutely lower than those of the people among whom they live.

The marriage-rates and birth-rates of the Jews are lower than those of the Christians; they increase more rapidly because they lose fewer children by death. The Jews are less attacked by infectious diseases than their neighbors. Syphilis and alcoholism are comparatively rare among the Jews.

Diabetes is very frequent among the Jews. All the functional neuroses are more frequent among the Jews, while the organic nervous diseases are less so. Insanity is two to five times more common among Jews than among Christians. Blindness, varicose veins and hemorrhoids are very frequent among Jews.

These peculiarities are due to the past history and habits of life of the Jews, and not to racial characteristics.

When the Jew mixes with Christians and adopts their customs, these distinctive characteristics disappear.

Vital Statistics for Germany for 1897.[5]—The infant mortality, as shown by the returns of 1897, exceeded one in five, and showed no tendency to decrease. More than one-third of the deaths of infants under one year were due to "gastroenteritis," while whooping-cough was more fatal than diphtheria, scarlet fever and measles combined. At ages 1 to 15, diphtheria was the main cause of death, though the mortality is declining, particularly in the large towns, owing, probably, to serum treatment.

Accidents killed 5,332 children. No less than one-third of the deaths during the active years of life (15-60) were attributed to various forms of tuberculosis, pulmonary tuberculosis accounting for 82,279. Even in the ages over 60, tuberculosis still occurs in nearly six per cent of the death certificates. The frequency of malignant disease has increased in this section even more than in the ages immediately below. The birth-rate gives an excess of fifteen per thousand over the death-rate.

Vital Statistics of England for the Year 1900.—The General Abstract,[6] or advance sheet, gives the population of England and Wales as 32,247,015; marriages, 257,139 (couples); marriage-rate, 15.9 per 1,000; births, 926,304 (470,784 males and 455,520 females, or in the ratio of 1,033 males to 1,000 females); deaths, 587,459; death-rate, 18.2; death-rate of males, 19.5; of females, 17. The marriage-rate of London was 17.9 persons married; the birth-rate, 29, and the death-rate, 18.6.

Regarding infant mortality, Reid[7] showed that the employment of mothers

increased infant mor-

...s the death-rate

...ns to 1,000 population ...g countries was: Scotland, ...d, 24.1; Denmark, 32.4; Nor-...9; Sweden, 29.4; Austria, 38.9; ...gary, 44.6; Switzerland, 28.8; Nether-...nds, 35.3; Belgium, 31.2; France, 24.8; Spain (1870), 35.4; Italy, 34.27; Germany, 36.9; England and Wales, 28.7.

To sum up, we thus see that Hungary gave the highest birth-rate, with 44.6 births annually per 1,000 population.

While France is said to show the lowest birth-rate, it should be remembered that many of our States, almost as large as France, give a still lower birth-rate.

It would seem, then, that while more males are born than females, nature compensates for this, to a large extent, by causing a larger mortality in males. Notwithstanding the deaths, the general population is steadily increasing, taking our globe as a whole.

The Medical Feature of the Treatment of Appendicitis.

MILTON J. LICHTY, PH. B., M. D.,
...sor of Medicine in the College of ...ysicians and Surgeons. ...Cleveland, Ohio.

...my purpose to criticise the ...the surgeon, or to deny that ..., if not most, cases of appendicitis ...e surgical as soon as diagnosis is made. All cases can be classified under three heads:

1. Acute cases, whether mild or severe, in which operation is nearly always safest when in the hands of a skillful surgeon, especially if the operation be done early.

2. Chronic cases, with a history, often obtainable, of a former attack not diagnosed, in which attacks continue to recur, often with increasing severity and frequency.

3. Doubtful cases, where the diagnosis is at once uncertain and difficult.

Under the third class there comes a line of cases in which there are definite symptoms pointing to lesions in other organs, as the rectum, ovary, uterus, stomach, gall-bladder, liver, kidneys, intestines, especially the colon, and even sometimes to lesions of organs not in the abdominal cavity. It is in cases of this kind, where symptoms, sometimes misleading, pointing to disorders in other organs than the appendix, which, after all, may or may not be the seat of the disease, that serious errors may be made, both by the surgeon and the physician. It is no credit to a surgeon to operate upon cases for appendicitis when there is no necessity for it. Such errors do occur, and sometimes they lead to a speedy fatality. Of course, the literature on this sort of error is not voluminous, but many physicians can recall such errors, either in their own practice or the practice of others—errors not usu-

ally published. On the contrary, the discredit is just as great upon either physician or surgeon who overlooks a correct diagnosis, or, who, after making such a diagnosis, allows his patient to pass from a favorable into an unfavorable condition without considering the advisability of operation. Here, then, is a line of cases where strict medical supervision may be necessary for the comfort of the patient, where sometimes long-continued observation is necessary before a case can positively be diagnosed either as appendicitis or a lesion in some other organ. It is in this third class where the medical feature in the treatment of appendicitis is of paramount importance. Under this heading, too, must be mentioned those cases requiring medical treatment while the surgeon is taking care of the surgical part of the case, as well as a considerable number of cases who have successfully passed through an operation, but who fail to regain health subsequently. How often do we see chronic cases, baffling all effort at a proper diagnosis, suddenly develop typical symptoms of a surgical condition. And how often do we hear of and come in contact with patients who say they had appendicitis years ago, had a successful appendectomy, but have never been well since. Too often the operation, in the mind of the patient, is the direct cause of the subsequent ill-health.

The following reported cases illustrate these points:

Case 1.—Mr. S., aged thirty-one, had his appendix removed ten years ago. He was never sick before his attack of appendicitis, and has never been well since. At the time of operation the appendix was removed, and there was general peritonitis, so that his abdomen was packed with gauze. Recovery was tedious. Since then he has been suffering with pains over the cecum, also pain over the left side, in the lumbar region. These pains occur several times a week or month, and are not relieved until his bowels are thoroughly evacuated, or until he has been given a hypodermic of morphia. With the cleansing of the bowel there is always an evacuation of much mucus, and sometimes undigested food. Upon examination, I find he has a dilated stomach, with a hyper-chlorhydra. There is, likewise, a left movable kidney, and there is tenderness over his cecum and gall-bladder. He does not consider the operation the cause of his trouble, but can not understand why he is not well. One can very easily see how a dilated stomach, with hyperacidity, would cause pain over the pyloris, and, possibly, catarrh of the gall-bladder, so also is there excuse for pain over the cecum, and in the left lumbar region, with a history of constipation, colica mucosa, and a left movable kidney. The patient has not been under observation very long. But a corrected diet, though liberal in quantity, together with the use of alkalies, laxatives, massage, and the electric current to the abdomen, have already given him great relief, and he is increasing in weight. The bowels are more regular, and he has been free from pain since taking treatment.

Case 2.—Mr. B., aged twenty-five, has always had fair health until he developed a chronic appendicitis several years ago. His appendix was removed in February, 1906. It was not perforated, and there was no general peritonitis, but the appendix was removed with much difficulty on account of its size, extending from the cecum beneath the colon to the liver. There were many adhesions. The patient made a quick recovery from operation, but after leaving the hospital he was much afflicted with pain in the right iliac region, and distress in the stomach after meals. The patient has a dilated stomach, which extends to or below the umbilicus. There was tenderness over the pyloris, with an enlarged and palpable liver. He has had many attacks of pain in the stomach and in the right lumbar region, as severe as any pains he had before his appendectomy. Some of these attacks were so severe as to require a liberal dose or two of morphia. Pyloric stenosis, with dilatation of the stomach and gall-bladder disease, ulcer, were considered, but finally ruled out with difficulty. After each attack of pain the first few evacuations of the bowels revealed large quantities of green and offensive mucus, mixed with fecal matter and some undigested food. On account of the distance to his home it was never my opportunity to see this patient in one of his attacks until several months ago. I always saw him some time

after the attack, after the catharsis was already begun, or after he had received a hypodermic of morphia. During his most recent attack, however, which occurred in the evening, I could easily outline a soft, doughy mass in the right colon, or cecum, as big as a man's fist, about which was most of his pain. Had I not known that his appendix was removed I would have considered operative measures. But he was given a hypodermic of morphia, a dose of castor oil, and large enemas of olive oil. The next morning he passed an unusual quantity of fecal matter and mucus. I feel that the patient had a dyspepsia with hyperacidity (which is not the less easy to treat on account of his dilated stomach), as well as mucous colitis (mucus is often found in the stools), and probably some bands of adhesions about his ileo-cecal region, which may occasionally cause a fecal obstruction. He has been taking much olive oil recently, castor oil occasionally, rectal flushes, followed with olive oil. This, with a more or less continuous administration of alkalies, as well as massage, and the interrupted electric current to the abdomen, has given him much relief. He has a liberal diet, and has gained twelve to fifteen pounds in weight, and though the patient is not yet well, I see that he can not get along without medical supervision.

Case 3.—Miss J., aged nine, had acute appendicitis, for which operation was done in May, 1906. The appendix was found perforated; general peritonitis was present, and many apparent tubercles upon the intestines. The wound was packed with gauze. The patient seemed to improve nicely for ten days, when suddenly symptoms of intestinal obstruction developed. The bowels were constipated or obstructed, and there was nausea and vomiting. This condition lasted six days. During that time free fluid seemed to accumulate in the abdomen. The wound was dry, the tissues seemed dead. During the entire week the patient received no food or water by the mouth, and but little through the rectum. A more desperate post-operative condition could hardly be seen or imagined. A second operation was out of the question. The Alonzo Clarke, or opium treatment, was consequently carried out, and the respirations kept as low as twelve to fifteen a minute. At the end of seven days the bowels moved voluntarily, and the patient began to convalesce. The convalescence was tedious, but the patient recovered. To me it seems that the post-operative treatment was almost as essential as the operation itself.

Case 4.—Mr. T., aged thirty-seven, was first seen in January, 1906. He gave a typical history of dyspepsia, in which were some suggestions of former attacks of appendicitis, or gall-stone colics. Physical examination showed a dilated stomach, with hypopepsia. The patient weighed only one hundred and twenty-two pounds, and is probably affected with a lesion at both apices of the lungs. He was put upon vigorous treatment and a careful diet. Five weeks after examination he developed an apparent attack of acute gastritis, with nausea and vomiting. The bowels were costive, and there was much tenderness over the gall-bladder, but no tenderness over the appendix. The next morning the patient seemed better. The temperature and pulse were normal, and there remained tenderness over the gall-bladder, while the lower part of the abdomen was soft and entirely free from pain. At noon the patient thought of leaving his bed. At five P. M. (less than twenty-four hours after the onset of the attack) his pain suddenly shifted to the lower abdomen. The abdomen became distended and rigid. Perforation of some abdominal organ seemed sure, but one could hardly say with certainty that the perforation might not have been in gall-bladder, stomach, or duodenum. However, operation was done in a few hours. A perforated or gangrenous appendix, adherent to the bladder, was quickly removed. The abdomen was drained through three openings, and the patient was returned to bed in a desperate and critical condition. To our surprise, however, he recovered from the operation, and is today in fair health. Convalescence was tedious. The patient has often remarked that he believed the careful preliminary and subsequent medical treatment, as well as the close observation during his attack, had much to do with carrying him successfully through his very critical condition.

Case 5.—Mr. H., aged thirty-three. He was afflicted with mucous colitis for some years, and came under my observation in June, 1902. Diarrhea of mucus stools was very annoying. Occasionally there was constipation. There were no attacks of acute appendicitis. Some of his attacks of diarrhea, during which there was an evacuation of much mucus, were very painful, but there was no localized tenderness, nor was there any alteration in temperature and pulse from the normal. The patient was under heavy official pressure, and seemed neurotic. During a temporary residence in Akron, in 1903, he had several attacks of cramps in the abdomen of more than usual severity. In the midst of one of these the patient left his office to consult me at my office in Cleveland. I then found tenderness over the appendix. All other signs of appendicitis were absent. A surgeon was consulted, and exploratory incision advised. At operation a long catarrhal appendix was removed. There was considerable induration of all the layers in the anatomy of the appendix. There were few or no adhesions. It was not a dangerous-looking appendix, though it had a safer appearance outside of the body than in. My first impression was that of erroneous diagnosis, and that I had treated a case of appendicitis for two years, thinking all the time it was mucous colitis. Three or four months after operation, though, the patient had a return of some of his former attacks of colica mucosa, but not so severe as those prior to operation. Medical treatment was again begun. It was continued methodically for a considerable time, and the patient today considers himself quite well. But I shall possibly never know whether the colitis was the cause or the result of his appendicitis, though it does seem to me that the medical treatment in this case, both before and after operation, was of great benefit to the patient.

Possibly a better name for this paper would be the preliminary and subsequent medical treatment in association with the operation for appendicitis. I believe there are few cases where medical treatment during a pronounced attack of appendicitis is justifiable or safe. And I never feel safe or comfortable in the management of an attack of appendicitis unless I have a thoroughly competent surgeon of my own selection at my side. However, I also believe that there is a medical feature in many of these cases before, during and after the operative treatment, which, if neglected, will be detrimental to the patient.

A Report of Four Interesting Cases of Stone in the Bladder.

BY WALTER D. GREENE, M. D.,

Clinical Professor of Genito-Urinary Diseases in the University of Buffalo.
Buffalo, N. Y.

The distinctive features of the first three cases are the foreign bodies in the bladder causing stone. The fourth case is somewhat unusual, owing to the great size of the stone removed from the bladder.

Case 1.—S. K., aged fifty-one; widower, consulted me in April, 1907, for pain in the region of the bladder; increased on urination. Temperature and pulse normal. Appetite poor; lost much flesh. Examination revealed the presence of stone in the bladder. Operated by the peritoneal route, and a stone extracted about the size and shape of a normal finger. The stone was phosphatic, and the nucleus was chewing gum.

Case 2.—M. G., aged seventeen; school girl, consulted me in October, 1900. Found patient extremely emaciated; pulse one hundred and twenty-four, temperature 102° F. Complained of excessive pain on urination. Urine contained much pus, and small quantities of blood. Sound revealed the presence of stone in the bladder. Two days later operation was done through the vagina, and a large phosphatic stone extracted; hairpin as nucleus. Girl made good recovery, gaining thirty pounds in flesh in three months.

Case 3.—A. B., aged thirty-six; unmarried; housekeeper by occupation; consulted me in February, 1900, for pain on urination. Pulse and temperature normal. Sound revealed small stone in bladder. Examination of urine revealed nothing

abnormal. The urethra was dilated and stone removed in that manner. Under an anesthetic three stones were removed. Examination proved them to be pebbles picked up from the lake shore. On being questioned, patient confessed to this fact.

Case 4.—G. S., aged thirty-two; laborer, born in the United States; German parents; habits not all that could be desired; drank from ten to twenty glasses of beer daily. Consulted me in January, 1898, complaining of pain in the hypogastric region; much pain on urinating and constant desire to urinate. Temperature 102.4° F., pulse one hundred and twenty; feeble.

Passage of sound revealed the presence of a large stone in the bladder, filling the entire cavity. His wife was told that he would soon die from septic infection unless operated upon, and the operation would probably cause his death. Operated next day by suprapubic method, and extracted a calcareous stone measuring eight and three-eighths inches in circumference. Patient died six hours after operation. The stone was cut in two pieces, and found to be phosphatic, with oxylate of lime as a nucleus.

Is the Treatment of Consumption by Garlic, Onions, or Other Vegetable Juices, Scientific?

BY ALBERT S. ASHMEAD, M. D.,

Director of a Tent Camp for Consumptives in the Pocono Mountains of Pennsylvania.
New York City.

It is forty years ago this coming winter that there lived on a mountain top—or very near the top—a consumptive in Nevada, in a cabin, one plank between him and the weather; the planks were not jointed—simply lath-battened; the snow would drift in, and on arising in the morning the patient was often obliged to toss the snow off the bed-covering onto the floor, then dress, and with broom or shovel, or both, shove the snow back into the cabin, in order to open the door, and then shovel it all out into the outer air. Then, with pail in one hand and ax in the other, he would travel down hill about four hundred feet in snow knee-high, chop open the spring and bring back a pail of water.

At times the temperature was so low that the pail of water, sitting inside of the cabin, near the door, it is true, but within three feet of a stove in which was a roaring wood fire, at three o'clock in the afternoon, would freeze from the bottom and sides toward the middle.

The mules from the mine (the Chollar-Potosi), on their way to water, passing the cabin, would poke their noses against the glass of the window, knowing that there must be warmer conditions inside.

That weather was some cold. I might mention, parenthetically, that this patient hardened his heart against the mules, and not one of them ever got in.

Several times he has stood in snow nearly or quite three feet deep at his cabin's door, and seen the stage coach below in the valley on its way east with the mail and passengers, traveling on the dry sage-brush desert plain. Under these conditions of life this man recovered his health, and by continuing the same lines of regimen he learned there, he has succeeded in living out the allotted span of man.

At that early date, long before our boasting science had told us that outdoor life was conducive to recovery from the greatest plague of our present day, this layman learned its lessons without knowledge of how it was done. I have had many conversations with this gentleman of means, and extracted many answers from him by questions which I have propounded as to his method of accomplishment, the good result; they resolve themselves into the simple fact that high, *cold* air, dry as dry can be, was the important factor. "Jerked meat" diet was another element in the cure.

Allow me to observe here that the idea that garlic, or any other of the species of *genus Allium*, is preventive, or curative for tuberculosis, no matter whether mixed or not with other juices of raw vegetables, and no matter what the experimentation of Cavazanni (*Lancet*, January 9, 1904,) on guinea pigs may show, is nonsense. Let me prove this:

According to investigations I have made relative to pre-Columbian tubercu-

losis in the Andes Mountains, twelve to eighteen thousand feet, where the air is intensely cold, where garlic is a necessary article of food to prevent the disease known as "soroche," a result of effects of high altitude, causing bleeding at the mouth, nose and ears, with vomiting and difficulty of breathing, the sufferer from soroche must return at once to a lower altitude or die, unless he has with him a supply of garlic, and eats thereof. Should he be an old Quechuan or Aymaran Indian, used to those Andean heights, with enormous racial development of chest, with short arms and legs, and a striking difference from us, in proportionate relations of those parts, due to the high altitude and rare air which have been acting through the preceding generations and ages of his evolution, to prepare him for these very conditions of life, and by a natural acquirement of general varicose condition of all his surface veins, he will escape soroche. Those who are not thus protected suffer more or less from the disease. Indians of very large development of chest do not suffer at all from "puna" or "soroche." This disease is a kind of inflammation of the lungs, brought on by the overexertion necessary at a mountain's great height. "Puna" (soroche) is brought on by working the normal-sized lungs at a vastly greater rate than ordinarily is necessary, in consequence of the very attenuated state of the atmosphere, and the deoxidation of the blood as a result. Onions and garlic are the universal remedy and preventive in man and beast in Andean regions, of this condition, in those who have not the enormous lung expansion necessary to resist its consequences. Tschudi considered that the first effects of this highly attenuated air commenced at twelve thousand six hundred feet elevation. Cats can not live at all at this elevation. The Aymaran and Quechuan Indians counteract the effects of high altitude on their blood (deoxidation) by eating ashes (an alkali), with coca leaves. This diet distends their stomachs with gases and prevents soroche or deoxidation of the red cells. A systemic vacuum results from the pressure of the intensely rarefied air upon the surface of the body. This is nothing but a diminution of oxygen tension. Chacoma, a native herb which stimulates the nerves of respiratory function, is also used, but lower down the mountains, Dr. Sarmiento claims that it has the same purpose as the garlic higher up. Now what is the condition of the air at altitudes where puna (soroche, bootie, parano), all names of the same affection, occurs? The air is very dry, on account of the altitude—at the point where the hygrometer goes back five degrees, it is four thousand meters high. This makes the skin of a person, when he has passed the three thousand meter stage, stretched and chafed. It sheds little scales. General uneasiness of respiration now results—the breathing becomes quickened, until by reason of elimination of all the vital functions, vertigo appears, and *want* of oxidation of the blood results.

Tuberculosis (consumption) was pre-Columbian in Bolivia, both in the Aymaran and Incan Indians. I have made a thorough study, for many years, of pre-Columbian diseases in America, and my articles on these subjects may be found published in the "*Zeitschrift für Ethnologie*," of the Berlin Anthropological Society, and "*The Journal of American Anthropology*," also in the American medical journals.

Uta (skin tuberculosis) is found represented on the grave potteries unearthed with Ancon and other mummies of old Peru, from Lake Titicaca, where Professor A. F. Bandelier, of our American Museum of Natural History, is working, and also in Chimbote. These little anthropomorphous clay bottles show on their represented human faces the mutilating results of this disease—noses and upper lips eaten away. Some idols of the Chibchas of South America show even the insect (a bug) on the chin of the vase, evidently inoculating the germ of this disease.

Dr. Ugaz, the Peruvian specialist of uta, says that tuberculosis-scrofuloderma of ancient Peru and modern tuberculosis (consumption) are identical, and that the presence of Koch's bacillus in both diseases proves the claim, put forth by myself and others, of their unity. Experimental inoculation with this Peruvian scrofulous material, called there the "evil incarnation," has resulted in the tubercu-

lation of the animal after a few weeks, and the presence of the bacillus in the strumous glands confirms the important doctrine and proclaims the identity of tuberculosis (consumption) and the uta of Bolivia and Peru. The inoculation of consumption in old Bolivia and Peru occurred through the intermediary of fleas, flies, mosquitoes, bugs, spiders and butterflies. The insects carried the germs from dead birds, especially parrots of the Andes Mountains, which are especially subject to tuberculosis. Aviary tuberculosis was thus the origin of human tuberculosis in pre-Columbian America.

Today, according to Dr. Ugaz, lung tuberculosis appears in those Indians of the Bolivian Andes who are affected with skin tuberculosis, which attacks primarily the face, hands, feet and other uncovered parts of the body. Auscultation of the lungs of such Indians shows obscuration of the lungs, crackling and rough respiration, or forced expiration below the clavicle, and dullness at the base of lungs. Thus, without any doubt, is proved that systemic infection can result from the original inoculation of the germ.

The germ introduced in the skin, finally infects the system, the lungs, by lymphatic transference.

In spite of persistent garlic-eating, or its equivalent effect naturally acquired, of those Andean Indians for many centuries, in spite of the climatic faction, deoxidation of blood corpuscles by dry, rarefied, cold air, applied for many generations, until their lung expansion had grown excessive enough to withstand the vacuum factoring of very high altitude, which produces in those not thus generationally acclimatized the disease called soroche; by the presence of insects carrying Koch's bacillus perpetually to the skin of those Indians, especially mosquitoes, four hundred species of which are known all over the world, and whose geographic distribution extends from the tropics to the polar circle, whose vertical range is known to be thirteen thousand feet, for they are found in the Himalayan range at that height, with an antiquity running back to the Perbeckian period we find the presence of lupus. We see, in spite of the garlic, and in spite of those natural factors curative of tuberculosis, that tuberculosis has not been extinguished.

Some experiments made by Mr. Mosso on the top of Monte Rosa, indicate that the difficulty in breathing caused by high altitude is due to lack of carbonic dioxide rather than oxygen, which causes the disagreeable symptoms called soroche. Carbon dioxide is one of the normal excretions of the lungs, and its presence in large quantity in the normal atmosphere indicate that the latter is unsuitable for breathing. Professor Mosso found that when at sea-level the barometric pressure was reduced two-thirds (that is, to five pounds per square inch, instead of fifteen), and the proportion of oxygen was increased so that its partial pressure resembled that of ordinary air; the symptom produced by high altitudes, difficulty of breathing, etc., occurred with violence. On the other hand, a mixture of oxygen and carbon dioxide, the breathing of which, in Turin, caused giddiness and nausea, when respired on the top of Monte Rosa, was distinctly agreeable, and produced a feeling of well-being and happiness.

Analysis of the blood suggests that an elimination of the proportion of carbon dioxide, caused by the low pressure, is the cause of "mountain sickness."

Another interesting result of Dr. Mosso's experiments was the discovery that when alcohol is drunk at high altitude, it fails altogether to produce its usual inebriating effects. There is no indication of either excitement or intoxication, and it appears that at such a height the nerve cells are no longer responsive to alcoholic stimulus.

At an elevation of two thousand feet (quite low) on the Pocono, at my tent camp, I have noted that water is very slow in boiling. It required a much longer time for the result at 212° F., than at sea-level. The people there, as everywhere else on a mountain height, crave enormous amounts of starchy food, in place of meat, excepting in the winter time. Every adult eats ten to twelve ordinary-sized white potatoes, and the enormous supply of ten or twelve slices of a large loaf of bread and buckwheat cakes at a meal. This starch-eater has a natural resistance to consumption. In a high place,

the too rapid hematization (deoxidation) is very abundant, for as soon as a person arrives from sea-level, one who is not used to the altitude, and who has not used much starch in his regular food, the urine will become very high-colored, and remain so for a long time, unless he changes to the starch diet. There is more hematin made and more deoxidation ensues than the system requires, or the real blood cells are stripped of its super-deoxidation of red cells. Atmospheric precipitation of a high elevation is very low on the Pocono; less than three inches. The winds are usually extremely dry, being nearly always from the west or northwest. The temperature there during summer ranges from 35° to 65° F., in winter zero to 30° F. below.

Such a climate is very antagonistic to consumption germs. The moderate cold throughout the year is an important factor. Exposure to this mountain air, for even a short time, obliterates fever, and by breathing the atmosphere, the sputa masses grow smaller. They dry out, and fewer are cast off, day by day, until finally there is none. The body weight increases forty or fifty pounds in from two to four months. The ruddy hue of health gradually returns, taking the place of the blanched cheeks. Apathy is replaced by mental alertness, and the cure of consumption occurs in eighty-nine per cent of cases.

This curing of consumption, by these facts would seem to be due not to anything else but improvement and nutritional metabolism, a rebuilding of the natural resistance to the onslaught of the germ in the wounded lung area. Non-occurrence of renewal of disease by the patient's reinoculation of himself (auto-inoculation), through faulty chyle or mesenteric gland deficiency, or by inoculation from other patients, are also elements in rapidity of the healing. Tuberculosis is incurable, if it is ever so, simply because patients constantly reinoculate themselves or each other. If we can stop this, then every patient might get well in the absence of a vast lung area involvement. Long submission to the climatic factors of a high altitude, other things being considered necessary to the cure, proteid greatly improved that he wishes to re-intercurrent affections, will obtain recovery in almost all cases, even with diminished lung function; the tissues that were lost, of course, can never be put back.

Garlic, therefore, which antagonizes the natural effects of altitudinal treatment in consumption, will prevent rapidity of cure by interfering with the metabolistic changes in the blood most favorable to the cure. Garlic prevents super-deoxidation of blood, and increased eliminating of carbon dioxide due to excessive starch diet, to which all mountaineers are addicted, even to the extent of becoming goitrous.

The following cases of cured consumption are verified by facts and of long standing. I have a patient cured of consumption by mere pure proteid feeding at a moderate elevation, independent of mountain air. He is six feet tall, large and broad, heavy, strong man.

Twenty years ago he weighed but one hundred and ten pounds. His occupation had been an engineer; stationary engineer —indoors. No appetite at that time; thin. Diagnosis: Consumption. He consulted Dr. Loomis (the elder), who told him he should go immediately to the region from which he came—Saugerties—and that he might live a year, probably no longer. He did not see his way to live without work; no income. He resigned his position and opened an oyster saloon, keeping outdoors as much as possible. He began eating raw oysters, when hungry; four or five at a time, each time drinking a glass of new ale. That was about the extent of his diet. The ale "eased his throat." After twelve or fifteen months he weighed about two hundred pounds. He resumed his occupation of engineer, and is now janitor and engineer of a prominent public school in New York City.

I have also a patient cured by proteids and outdoor sea-level life, employed by Bernheimer & Cooke, distillers. Last winter, he having consumption, the firm sent him to Spokane Falls to represent them there. He said to his friends who accompanied him to the Grand Central Depot, in this city, on the occasion of his departure that he might as well die there as to die here. He drank ale. He is now so greatly improved that he wishes to re-

turn, and would like the firm to find a place in the Adirondacks—hotel or otherwise—to represent them there.

A physician (also a consumptive) is his frequent companion there, taking note of his lung condition continuously, and has advised him to remain until spring. This patient has a brother here who also was, some years ago, suffering from consumption. Living down-town, this brother began to be outdoors as much as possible. I have seen him standing under an awning on the sidewalk at midnight in high winds and fast-falling snow. He has become fat. I have no further record of his case. As to the best ale for such patients, for both of them made their diet mainly ale and oysters, that is important, for too many brewers have become "chemists" for brewing purposes. Care must be taken in the selection. In England, about a year ago, there was much uproar and protest in the daily journals over disclosures of brewers' methods in "the best known brands of ale;" no names stated. *Arsenic was used.* The poisonous effects of this and other drugs used evidently by an error on the part of the compounding brewmaster, caused investigation and discovery. The undue proportion found present, however, *might be good for consumptives.* Certainly arsenic would not be a bad combination with new ale a diastasic or enzymic for a consumptive's nutrition.

In the camp treatment of patients in the Pocono Mountains of Pennsylvania, I used meat, raw. I do not know whether it is curative. But I can speak from professional experience of the *instant* assimilibility of what is known as "scalloped beef." Some years ago I gave the Salisbury treatment for obesity, a most effective but irrational course: Hot water and beef, and nothing else. In three weeks I had reduced a certain patient from two hundred and one pounds to one hundred and seventy-one pounds. But his stomach was paralyzed; seemed to be in a shriveled state, as become one's finger-ends when immersed too long or too frequently in hot water. Even water was distressful to it. This "treatment" provides for such a contingency by "scalloped beef," as it was called. I gave then this "scalloped beef," and in three days my patient, so badly damaged, was on full and normal diet, to which he afterwards adhered.

Here is the recipe, as made in the Pocono camp:

1. *Scalloped Beef*—Take a piece of the upper part of the round of beef about the size, superficially, of the hand.

2. Denude this of all fat and sinew, so that nothing remains but the red flesh.

3. Take a somewhat heavy knife, and with its edge tap the meat lightly, not cutting it; simply to macerate it. Do this at half a dozen different angles.

4. There will be produced a fine, fuzzy surface, which is to be collected by scraping it off with the edge of the knife, always being careful not to cut or incise the flesh, or tear it.

5. Transfer this collected fuzz, and repeat the tapping process until as much is gathered as is desirable for the meal.

6. Put it in a pan of *cold* water, and place it over a fire.

7. *Keep stirring constantly;* never losing sight of it for so much as half a minute.

8. The instant that it turns gray, take it off the fire. A moment too long—a moment after it becomes gray—it will curl and become useless.

9. Drain, season with salt to taste. I believe this to be the quickest digestible nutriment on the face of the earth.

The first teaspoonful will be felt by the patient to be immediately grasped by the eager but nigh helpless function.

Of course, in my shriveled stomach or obesity case there was no systemic weakness. I think in consumption the milk and eggs given at the same time should be well shaken, as a barkeeper prepares a milk punch. The milk thus becomes ærated for the consumptive's weak stomach, and for most patients is much more palatable.

In the case of the "scalloped beef," it is the beef that the patients eat, not the juice. The effect upon them all seemed, as I interpreted it, thus: The beef being thoroughly and only heated (possibly a bit softened), was directly assimilable, and while not in the least devitalized, was not cold and raw, nor did it possibly retard the weakened digestion faculty. This view, I

remember well, presented itself instantly to me when I had first used it on the patients. It could not have been plainer had their stomachs talked.

Practical Disinfection.

BY HENRY E. HANDERSON, A. M., M. D.,
Cleveland, Ohio.

The popular idea of disinfection is to take a few spoonfuls of some disinfecting agent and add to the material to be disinfected, and the thing is done. As a matter of fact, disinfection is a subject which requires considerable care and experience. The most glaring fault of the majority is the tendency to use too little of the disinfectant.

Disinfection, of course, means, as we understand pathology nowadays, the destruction of germs. A disinfectant is a germicide. There are various kinds of germs, some beneficent, some malevolent, some more dangerous, and some less, and for that reason there must be a choice of disinfectants. What will disinfect in chicken-pox will not, necessarily, answer in small-pox.

Perhaps the best guide to disinfection is the character of the germs. Some germs are propagated by spores, others by division. The former are very tenacious of life, and when we have this sort of germ to deal with we must use considerably more powerful disinfectants than in those which propagate themselves by division.

Bearing that fact in mind, the subject of disinfection is very simple. There are three or four disinfectants that we may use with perfect certainty that they will destroy *any* germs. Therefore, these are best for general use. It is not expected that the average man will know the character of the germs to be destroyed.

In the first place, one of the best disinfectants, always obtainable, is boiling water. Steam, an equally good disinfectant, is not always available. To disinfect the discharges in typhoid fever it is necessary only to use *enough* boiling water, when the disinfection will be just as certain as can be obtained by any disinfectant you can use. But the temperature of the water must be raised to the boiling point. In the use of boiling water we have a disinfectant that can be obtained anywhere; there are no poisons to be handled; and it can be used with perfect safety for even the most resistant germs.

Next to this comes, perhaps, bichloride of mercury, commonly called corrosive sublimate. In a solution of one to one thousand or one to five hundred, we have a perfectly reliable germicide, if sufficient is used. The precaution should be taken to use a sufficient quantity of this disinfectant, particularly for infectious material containing a considerable amount of albumin, since bichloride unites with the albumin and part of it is rendered inert, so that in disinfecting stools you must use a large quantity. If you err on the side of using more than is necessary, no harm is done, and the bichloride is not expensive.

Next in importance is chlorinated lime. That also is a valuable disinfectant and reliable if used in a strong enough solution, six ounces to the gallon of water. The chief objection to its use is its odor, but for the disinfection of sinks, water closets and places of that sort it is very useful.

When we come to the more modern disinfectants, they are legion, and many of them are very useful in cases of minor importance, like measles, chicken-pox, etc.

In the less troublesome diseases we have the old and popular carbolic acid, one part to twenty, but it can not be relied upon to destroy the more resistant germs.

For the disinfection of rooms, we have sulphur, brimstone, formaldehyde, etc. If properly used these answer for the destruction of the less virulent germs. Of sulphur or brimstone we must use not less than three pounds to one thousand cubic feet of space, taking great pains, of course, to see that all crevices in the room are filled up, keyholes plugged, fire-places closed, and registers covered, etc., in fact, make the room to be disinfected as nearly air-tight as possible. Care must be taken that all the furnishings of the room be properly exposed to the fumes. After using both these disinfectants the room should be

left closed for from twelve to twenty-four hours. After this time the room is thrown open, and the air allowed to circulate as freely as possible.

None of these disinfectants will penetrate a mattress satisfactorily, and it is doubtful if a bed can be successfully disinfected, except, perhaps, by steam.

Biblical Criticism.

BY R. C. CAVE.

St. Louis, Mo.

Many readers of the BRIEF are old enough to remember when criticism of the Bible was supposed to be an almost unpardonable sin. The Bible, from cover to cover, was believed to be the divinely inspired and infallible word of God; and men were told that everything written therein, whether it seemed to them reasonable or unreasonaable, true or false, good or bad, must be accepted by them with unquestioning faith. Whoever dared to doubt the literal truth of the temptation of Eve by the serpent, the speaking of Balaam's ass, the swallowing of Jonah by the whale, and other such stories, was supposed to be denying God, and arraying his puny reason against the Most High. But the superstitious worship of the Bible, which raised it above criticism, is largely a thing of the past. The most intelligent and scholarly men of our time, instead of regarding it as the infallible Word of God which must be unquestioningly believed, are boldly questioning its authenticity and credibility. This questioning is not that of irreverence, nor is it confined to men out of the church. Enlightened ministers of the gospel, as well as learned seekers for truth, who have no church affiliations, are bringing to bear upon the Bible the searchlight of the most rigid criticism, to determine its authorship, character and value. The church of today, through its most scholarly and influential representatives, concedes the legitimacy of subjecting the Bible to the same criticism to which we subject other books, and accepting or rejecting the conclusions of that criticism as they may commend themselves to our judgment.

In thus conceding that it may be criticised as we criticise other books, the church logically surrenders the old claim that the Bible gives an absolutely authoritative rule of faith and practice. It can no longer be said that any doctrine must be implicitly believed because the Bible teaches it; for it is admitted that we may legitimately question the authenticity and credibility of the Bible itself. The church can no longer appeal to what was said by the writers of the Bible as an authoritative standard to which we must conform our faith and conduct; for it is conceded that critical investigation must decide who those writers were, what they said, and whether they are worthy of credence. To admit man's right to criticise the Bible, and to accept or reject the conclusions of such criticism as they may seem true or false to him, is to admit the right of appeal from the decision of the book to the decision of reason. It is, therefore, to deny that the book is a final authority; for a final authority is that from which there can be no appeal—that whose decisions must be accepted under any and all circumstances. Hence, in conceding the legitimacy of criticism to ascertain the truth about the Bible, the church virtually concedes that the Bible can no longer have its old-time right to command, and that the authoritative basis of traditional theology is gone. Men may still believe the doctrines of traditional theology, if those doctrines seem reasonable to them, just as they may believe the speculations of Greek or Hindoo philosophers that seem to them reasonable; but they can no longer claim to hold these theological dogmas by divine authority—they can no longer teach their theological creed as a "thus saith the Lord," to disbelieve which is to disbelieve God and deserve eternal damnation.

But when it is admitted that the Bible is not a divinely inspired and infallible revelation of truth, it does not follow that it must be cast aside as altogether worthless. We do not regard other books as absolutely authoritative, or as altogether free from errors; yet we use them to get whatever of truth and helpfulness they

can give us. On the same principle, even though we can not accept the Bible as an absolute authority, we should not discard it altogether; but, wisely using our reason to discern between the truth and falsehood in it, we should hold fast to all its teaching that commends itself to our judgment as true and beautiful and good. And regarding the Bible in this rational way, using reason and conscience to distinguish between the good and bad in it, instead of holding them in slavish submission to it, we will find it more helpful than ever before. We will find that all of the Bible which is in accord with the divine spirit, and which helps to form the truest life and the noblest manhood, will remain to us with increased clearness and certainty and character-molding power, because freed from what our reason and moral judgment can not approve.

Fascia of the Pelvic Floor—Perineal Fascia.

BY BYRON ROBINSON, B. S., M. D.,
Chicago, Ill.

(Continued from page 863.)

The vaginal portion of the levator ani fascial proximal is endowed with considerable strength and it becomes blended with and is lost on the vaginal wall. The rectal portion of the levator ani fascia superior passes to the rectal wall, becoming continuous with the fibers and blending with it. There is a strong fillet passing between the rectal and vaginal canal.

The rectal portion of this fascia which passes to the rectal wall, has been termed the ligament of the rectum. This fascia forms a strong support to the muscular wall of the rectum.

It is not an argument very rich in facts to say that the perineal body is to completely occupy the space in that region. It serves as an attachment for one end of the levator ani muscle. A subject which I have not found in text-books is that in many parts the fascia of the pelvis consists of many distinctly defined layers which can be cleaved from each other. For example, the fascia over the coccygeal muscle may be cleaved in several layers and the same may be said, but to such a degree, of the levator ani proximal. Several thin, transparent planes of fascia may be cleaved from the obturator fascia proximal. Even the levator ani fascia distal, which is very thin and compact, may be cleaved into two or more planes. The obturator fascia distal is a very powerful fibrous plane of fascia and may be cleaved on each side into thin planes, but the central plane is a thick, powerful, individual, somewhat coarse fibrous membrane. The powerful obturator fascia distal is cleaved split, for the transmission of the pubic vessels and nerve. The canal formed by the separation is known as Alcock's canal. The several fibrous membranous planes of some of the fascia in the pelvis endow it with enhanced strength and utility. One plane may become lacerated, tear without the other practically being affected. Multiple cleavage planes are characteristic of fascia in other localities, and combined are more capable of resisting trauma than a single plane.

The coccygeal muscle arises from the spine of the ischium and lesser sacrosciatic ligament, becoming inserted into the side of the coccyx and two lower sacral vertebræ. It is a flat musculotendinous angular plane, aiding to close the posterior pelvic exit. Its ventral border is in contact with the distal border of the levator ani muscle of which it is practically a continuation backward and covered by the same fascia, viz., the levator ani fascia superior. The posterior border bounds the anterior margin of the great sacrosciatic foramen. The lesser sacrosciatic ligament, which is formed by a degeneration of the superficial muscular fibers of the coccygeus, takes the place of the continuation of the levator ani fascia inferior. The coccygeus muscle is fading from existence, belonging originally to a large-tailed animal. The origin and insertion of the coccygeus muscle and lesser sacrosciatic ligament are identical. They are so strong that practically they never yield so as to be involved in colpoperineorrhaphy. However, the coccygeus muscle is described in order to show that its fascia should be named the coccygeal fascia, which can not admit of confusion.

The distal surface of the coccygeus muscle is doubly strengthened, not only by the lesser sacrosciatic ligament, but by the proximal surface of the great sciatic ligament which represents the proximal tendon of the long head of the bicep femoris. The tendon of the long head of the biceps formed an attachment at the tubercosity of the ischium. The coccygeus fascia covers the coccygeus muscle and has an area of about three and one-half square inches on each side of the median line of the pelvis, a combined area of seven square inches.

The pyriformis muscle arises from the lateral portions of the second, third and fourth pieces of the sacrum from the distal border of the great sacrosciatic notch and from the great sacrosciatic ligament. It passes from the pelvis through the great sacrosciatic foramen, becoming inserted into the proximal border of the great trochanter. It is the most dorsal muscle which aids in closing the pelvic outlet. It serves as a bed on which the sacral nerves may rest. It is covered by the pyriformis fascia, which is a continuation of the obturator fascia proximalward and the coccygeus fascia ventralward. After leaving the obturator and the coccygeus fascia it rapidly diminishes into a transparent thin fibrous membrane. It is perforated by the internal iliac vessels which leave the pelvis by the great sciatic foramen. The pyriformis fascia is attached to the surface of the sacrum internal to the origin of the pyriformis muscle from the dorsal border of the coccygeus muscle to the ileopectineal line, which passes along the border of the wing of the sacrum to the sacro-iliac joint and finally it is attached to the proximal margin of the great sacrosciatic foramen from the ischial spine to the sacroiliac point. The pyriformis fascia covers an area of about five square inches on each side of the pelvis.

The sacrum is lined by a thin, fibrous membrane which we will name the sacral fascia; hence the internal pelvis is lined by the obturator fascia proximal, the levator ani fascia proximal, the coccygeal fascia, the pyriformis fascia, and the sacral fascia. This nomenclature we recommend as simple and as facilitating the easy acquisition of the internal fasciæ of the pelvis.

The use of the levator ani fascia proximal is: (*a*). to sustain the pelvic viscera, and is analagous to the fascia transversalis-abdominalis; (*b*) to form a receptacle pouch on each side for the pelvic viscera, which assists in closing the pelvic outlet, proximal, the muscular floor; (*c*) to fix the pelvic viscera; (*d*) with its proximal pad of fat and snow-white connective tissue, to support the pelvic peritoneum; (*e*) to resist the pressure of the abdominal muscles and the diaphragm, and (*f*) to serve the useful purpose of separating the perineal tissue from the peritoneum.

This latter anatomic condition limits inflammatory and infective processes from either perineal or peritoneal spaces. Further the levator ani fascia proximal forms the pelvic floor, and by its strength prevents pelvic hernia. The blood-vessels are placed proximal and the nerves distal to the levator ani fascia proximal. The levator ani fascia proximal and distal limits nearly all fistulæ to one or to one and one-half inches proximal to the anus. A disadvantage of the levator ani fascia proximal is that it is perforated by nerves and vessels which carry sheaths of connective tissue; these sheaths allow infective processes to pass from the perineal tissue to the subperitoneal tissue and vice versa. Deficiencies occur in the fascia, excavations which are filled with fat.

The fascia of the pyriform muscles consists of an extension dorsalward of the obturator proximal and levator ani fascia proximal. Both fascial planes blend, the one from the ventral margin of the sacrosciatic foramen and the other from the dorsal margin of the coccygeus into a thin fibrous membrane which envelopes the pyriformis muscle and the sacral plexus of nerves. The pyriformis fascia is perforated by the gluteal vessels and nerves to gain the gluteal region. This plane of fascia is so thin and delicate that one can scarcely dissect it without lacerating it. The levator ani fascia distal (anal or ischiorectal fascia) lies in immediate and intimate contact with the distal surface of the levator ani muscle. This fascia begins at the white line and

becomes lost on the rectal wall. It is profoundly and intimately connected with the muscles. The levator ani fascia proximal and distal blend with the rectal wall about one-half to three-fourths inch, the anus, and rectal perforations generally occur distal to the insertions of this fascia. The fibers of this fascia are included in all deep suturing of extensive colpoperineorrhaphy. By including its fibers in the sutures, the relations of the levator ani may be partially restored to the normal relations. The sacral and coccygeal fascia lines the ventral surface of the sacrum; it has localized points of increase and decrease of thickness. The thickest portions are those located along the lateral margins of the sacrum, and especially around the ventral sacral foramen.

TRIGONUM UROGENITALE OR TRIANGULAR LIGAMENT.

The triangular ligament (deep perineal fascia) of the lateral pelvic walls closes the pelvic floor ventrally. It is the result of the union, coalescence, of the bilateral obturator fascia extending from the lateral pelvic walls toward the center. It is a prolongation of the obturator fascia across the pubis, and Winslow called it the ligamentum interossei pubis; Carcassone, the ligamentum perineale; Colles, the ligamentum triangulare urethræ. It is the deep blade of the fascia perineal and is an integral part of the obturator fascia. It is the middle fascia of the perineum, or Camper's ligament. It is the trigonum urogenitale, the triangular ligament. It occupies the deficiency occurring between the ventral or pubic insertions of the levator ani muscle. It is a wonderfully powerful fibrous structure in fixing the distal end of the vagina. It is stronger in males than in females. It is the structure which retains, maintains with powerful grip, the distal end of the vagina in a ventralward and proximalward curve. The vagina pierces the triangular ligament whose fibers fix, interweave themselves in and around the vaginal walls. It joins dorsally with the distal margin of the distal edge of the superficial perineal fascia. If one dissects all structures from the vagina except the triangular ligament will become apparent at once what a powerful support it is to the distal end of the vagina. The triangular ligament, as its name implies, is triangular in shape, aponeurotic in structure, extending as a tense fibrous septum between the ventral part of the perineum and pelvis. It is attached on either side to the rami pubis and ischium. Its distal or dorsal margin is ill-defined, blends with the superficial perineal fascia at the ischioperitoneal fascia, where it gradually loses itself on the distal surface of the levator ani muscle. It sustains and fixes the urethral canal. It is pierced by the vagina at its base, dorsal, its weakest portion. It serves the useful purpose of connecting the bladder and vagina to the pubis and of retaining adjacent organs in fixed relations. By its connection with the ischioperineal ligament (fascia) and levator ani muscle it serves to strengthen the distal region of the pelvis dorsally and aids to fortify the rectum with its muscles. By dissection, it is plain to see how the triangular ligament closes the perineal triangle and the levator ani closes the dorsal triangle. The triangular ligament extends dorsally on each side of the vagina and blends not only with the distal ledge of the superficial perineal fascia, but very intimately interweaves and blends with the ischioperineal ligaments, making a powerful fixation for the vagina at its distal end. The triangular ligament in conjunction with the ischioperineal ligaments lends to the perineal body a "Punctum Mobile." In perineorrhaphy much attention should be given to the factor of including considerable parts of the triangular ligament, levator ani fascia proximal and distal and the ischioperineal ligaments in the deep suture, which secures a ventralward curve for the vagina, and also by forcing medially adjacent perineal tissues, it aids in producing the normal curve of the rectum ventralward. This ligament is a very important structure, serving many purposes of support and aiding in repair. It is continuous with the levator ani fascia distal and the levator ani fascia proximal. The superficial layer of the deep perineal fascia of Colles is a strong fibrous membrane. It extends from one ischiopubic ramus to the other. This

membrane blends dorsally with the margin of the triangular ligament, producing partly ischioperineal ligaments. The superficial layer of the deep perineal ligament is less in extent in females than in men, on account of being pierced by the vagina. In perineorrhaphy it is of considerable aid in restoring the relation of the parts by allowing the deep sutures to draw the fascia medianward. The ischioperineal ligaments extend from the ischial tuberosities to the perineal body. They are strong aponeurotic bands of a very resisting character. They result from the union of the lower border of the triangular ligament with the deep layer of the superficial fascia. The fibers of these ligaments play an important role in extensive colpoperineorrhaphy. These ligaments form a conspicuous structure in every dissection of the female perineum. In the advancing head the ischioperineal ligaments are put on the stretch and gradually forced backward. Should they rupture, by extensive flap-splitting and deep suturing the two layers of fascia which blend to make the ligament could be partially restored.

(D) THE PELVIC VISCERA.

The Pelvic Viscera. { 6, Bladder. 7, Urethra. 8, Vagina. 9, Uterus. 10, Rectum.

The Pelvic Viscera.—There can be but slight doubt they are intimately connected with the pelvic floor and compose part of its supporting structure. In studying the physics and repair of the pelvic floor they can not be omitted. The distal portions of the bladder, urethra, vagina, rectum and cervix are knit and blended inseparably with the pelvic floor. The urethra has an intimate connection with the vagina, the ventral portion of the pelvic floor, and resists intra-abdominal pressure to a certain degree. The connection of the bladder by visceral layers of fascia to the pelvic wall is the most important. The wall of the vagina is fixed in the wall of the pelvic floor by fascial and muscular attachments; hence, it aids to resist intra-abdominal pressure. Also the vagina is firmly attached to the urethra, bladder and distal end of rectum. The distal end of the rectum is an intimate portion of the pelvic floor. The cleavable planes of visceral fascia aid to fix the rectum and anus in the pelvic floor. Connective tissue attaches it to surrounding tissue and viscera as well as its intimate connection to dorsal vaginal wall and perineal body.

Is the uterus a part of the pelvic floor? I can not agree with Hart that the uterus merely rests on the pelvic floor and is not suspended. I must consider the uterus a part of the pelvic floor. The cervix is embedded in the pelvic floor and is a part of it. The uterus being suspended by the bladder and vaginal attachments, also by the broad, but especially the sacro-rectal ligaments aids to resist the intra-abdominal pressure. The idea that the uterus is a key in the pelvic floor, I think, should not be abandoned. In vaginal hysterectomy ample evidence exists that the sacrorectal ligaments are the solid, powerful supports of the uterus and they are interwoven with the cervix in the pelvic floor.

[Written for the MEDICAL BRIEF.]

Race Suicide.

BY J. A. HOUSER, M. D.,
Author of "Is Marriage a Failure?" "Knocking at the Gates of Hell," "Beautiful Woman," "Zenda," "The Spirit of Life," etc., etc.
Indianapolis, Ind.

(Continued from page 875.)

Negroes Barren.—In amalgamation of the negroes with the whites, a state so much sought for by the negroes, is fast coming the suicide of the race. Another evidence of man's tendency to seek his own destruction.

There are two ways by which the negro obliterates his race by mingling with the Anglo-Saxon. The creative power to transmit race, life and color is much stronger in the white than the black race. If a black man and a white woman become the parents of a child it will be half white, or equally divided in blood between its parents. This shows the white female to have as much transmitting power as the black male. But if a white man and a black woman produce a child it will be three-quarters white. The white man has greatly more race-transmitting power than the

black woman. So, through amalgamation of the races, would fade the color to the white.

Still a more potent factor than this menaces the negro race in this country: the barrenness or sterility of the mulattoes. This condition appears in about the third or fourth generation, among many yellow people. Especially is there no productiveness present when two of them, the strain of three or four generations of amalgamation, unite. In many cases they remain childless through many years of seeming sexual vigor. Either of such might show some limited procreative power united with a companion of pure white or black blood.

The last United States census shows the negroes not to be equalling the whites in the ratio of births, and, for a want of more vitality in the children the negroes succumb to the diseases of childhood in a greater proportion than the white children. In one county in Indiana, where there are several hundred negroes, it is reported that there has not been a birth in a year.

The loss of the creative power seems greatest to the negro when amalgamated with the Anglo-Saxon, and probably greater in this climate than it would be in the tropics. It surely seems to point to a settlement of the negro problem in the United States.

But in South America the various mixing of races shows, so far as I know, none of the effects of sterility. In some instances some remarkable and beneficial effects of miscegenation are seen.

The Semitic peoples invaded Ethiopia eight thousand years before Christ. They subjugated the negroes with the selfish designs of a race of commercial adventurers, consciously and knowingly. But the negro women subjugated the Semitic men, with the result that a new race was formed, the Negroids. Atavism, even unto this day, though a hundred centuries have intervened, points to the past mingling of the white men and the negro women. The observer of atavistic handwriting on the walls of living, human history, need not remain long on the crowded streets of any great city in the world to see the translated message from the remote past, in far-away Abyssinia. The occasional thick lips, flattened nose and curly hair of some Semitic descendant of the invader, reminds us that life never dies.

These signs of this, the marking of an epoch in race history, disappear to again come to surface at long-separated periods, like the driftwood in the eddies of a flooded river, collecting here and there to be scattered by the rushing waters, and again collected miles below. In this case, let the miles be called centuries in the river of human life, and the driftwood the cell-formation of atomic life that has drifted in the stream all these eventful ages.

In the United States white men are more and more mingling their blood with that of the dark woman of Africa, as black men are with the frail and pale females of weakness and passion.

With some negroes the desire for immoral relations with white women becomes the mania of insanity. This is to be expected when an inferior race, whose animal propensities dominate the moral and intellectual forces, is placed on the plane of equality with the white race. It in this which leads the black fiends to assault and murder their white victims. Though swift and barbarous revenge is, usually, inflicted upon these beasts, the terror of a white man's revenge can not overcome the temptation. Should these assaults continue and increase, race suicide might be more rapid than that caused by sterility incident to mixed blood.

The number of negroes who have white wives is increasing with time. Though all the States have, I believe, laws against miscegenation, passion overthrows law and animal instinct defies decency. It is claimed that ten per cent of the white women, thrown among negro men as their equals, in certain menial work in cities, become the paramours of their black companions. If this is true, as it seems to be, it is but another evidence of the depravity engendered when the noble, though women, are degraded to the condition of servitude on an equality with the debased. Pope's philosophy applies here:

> Vice is a monster of so frightful mien,
> As, to be hated, needs but to be seen:
> Yet seen too oft, familiar with her face,
> We first endure, then pity, then embrace.

Danger in Too Many Children.—While the falling off, to a great extent, in this country in the numbers of the better classes of Americans, or any other country, would be a calamity, a greater evil will surely follow in the excessive birth-rate of all classes, when it reaches the stage of crowding. America is a greater and a better country with our present number, or a hundred millions, than it can ever be with five hundred millions. In controlling the birth-rate and limiting immigration lies our permanence and our greatness. But this may put the national prize beyond the circle of possibilities, surely beyond the probabilities. It is in the fact that the birth-rate of most of Europe and all of Asia is too high that America has become the dumping-ground of their human refuse. France rises above this unwise and unbalanced condition, calm and serene, in the wisdom of preparing for human necessities. France has reduced the birth-rate to a balance with the national resources. Since the land of France can not be increased, the number of the people is wisely limited to the measure of acres. France considers an ounce of preventive better than a crowded condition, which would drive her children to seek homes in an alien land. This has been in direct opposition to the teachings of the church that has dominated that country for centuries, but it was a necessity, and necessity knows neither law nor religion when fate commands.

Of all the nations of Europe, France is the happiest and the best satisfied with home. It may not be overdrawing it to say that the French are the most satisfied people in the world. This they evidence by staying at home, while the overcrowded condition of other European countries drive their starving children over land and sea to find the comforts of life. Of the more than one million one hundred thousand who sought homes in America in 1906 but few French were to be found. These distressed exiles of misery came from countries where the blindness of passion is stronger than the philosophy of human affairs.

Though the world may criticise France as it will, the fact remains that France has avoided the question of unequal conditions between babies and bread, that other nations fail to comprehend. While other countries trusted to Providence and were overwhelmed in the rising tide of helpless, starving humanity that, finally, must be pushed from their native land, to go among strangers for bread and servitude, France trusted to reason and reaps the reward of peace and plenty.

The nation which fails to solve the problem of babies and bread lacks the statesmanship of a great people. This statesmanship must be found with the people, and rise up from them, and never be expected to come down from the politicians, who seek office for personal gain, and not for the welfare of all.

"Ill fares the land, to hastening ills a prey,
Where wealth accumulates and men decay."

A Great Age.—I would not deny that we live in a great age. The wonderful genius of this period marks an epoch in the world's history. In some ways we can justly claim to surpass all past time and works of man. Especially true is this of mechanical inventions, and in systems of business combinations. Our machinery is little less than a beautiful acting miracle. Without the senses of flesh it performs the most delicate work of the hands. Its adjustment surpasses the eye in accuracy, in delicate lines and curves that human sight can not trace. Machinery works out the problems of science where human patience wearies and fails. It carries messages on wire where human feet can not go, and snatches the wings of the wind, and sends intelligence on the vibrating bosom of the air. It drives its myriads of ships through the sea, and sends its countless trains over the land at a speed and with an exactness that challenges human understanding. Finally, it seems to be cramped for space in the narrowness of continents and oceans, and now invades the sky and demands the right-of-way from the clouds. Besides these things, the mechanical works of the ancients are but toys for the amusement of children.

The most colossal works of the ancient Orientals are but crude piles as compared with the elegance and utility of a great modern building. The golden house of Nero, and the ivory palace of Ahab were

but evidences of barbaric wealth compared with the palaces of today.

The New York subway is more wonderful than the Hanging Gardens of Babylon, and the Brooklyn Bridge far surpasses the Pyramids of Egypt. These great American structures serve a necessity of humanity. The ancient ones only pleased a fancy—one built to satisfy a homesick woman, and the other for a grave, or to record the height of the water in a flooded river. A toy or a pet monkey would have done for the Babylonian, and a hole in the rocks would have served to hold the bones for future archæologists; and a stake, driven in the side of a hill, would have reminded the Pharoah where the water reached.

This unequal comparison is caused by the world having gone mad after the modern god (a transformation of the other one made by inserting an "l" in the spelling).

Great things are done that they may make money for men. The combinations of this age encroach so much upon the individuality of man that he finally becomes a unit lost in the numbers. He is but a part of a machine whose soul is a system.

This rushing of the world by machinery is not an unmixed good. Go to the farm for a lesson, if you will. Modern machinery cultivates the earth so well that it produces double, thribble, quadruple. But does it not do so by taking four times as much as formerly from the soil, reducing its productive life by three-fourths? The vital substances of the ground are so much, as the water in a pool. If either is removed faster than it is refilled it will, in time, become exhausted. The forests, the fountains of oxygen, have been reduced to but a fringe, while the great furnaces which consume much of the forests, and all the coal that is mined, consume the waning supply of oxygen so rapidly that the time will come when it will be a commodity to manufacture and sell. These things invite race suicide.

In the dump of a city is the doom of the nation. The life of the land is taken to the markets of the city to there find its way to the sewer and the dump, burned up or carried away by the rivers to sink in the estuaries or rise in gas. But the earth is robbed. From her generous bosom we snatch the elements of life as ruthlessly as a wolf takes a lamb from the fold, and have not even the poor grace to lay the ashes back to rest and nourish.

While we have surpassed the ancients in mechanical genius, we have also surpassed them in destroying the earth, the source of our own life. It is another story of the goose and the golden egg.

While the world has gained in mechanism, it has lost in philosophy, eloquence, poetry and statesmanship. Even more has it lost in the loss of sentiment. Sentiment, that sweet dove, the messenger that flies from soul to soul with love and peace! When it is dead, then let all the world die. To live without sentiment would be existence without the joys of living. What a flower is to the garden, the rainbow to the sky, or the twilight is to the night, sentiment is to human life. It loves the blue eyes of the girl, it kisses the lips of the babe, it waits with patience and fidelity at the couch of suffering, and dismisses the loved ones back to God, whispering, "We shall meet again."

Without sentiment poetry is only mechanical jingle, and oratory has no soul.

In the evolution of conditions human thought has kept pace with the change. It has taken on the features of a mechanical grind, and is a part of the machine work of the times. There is no orator today whose matchless gift of a soul's portrayal of human thought, philosophy and passion reaches the beatific heights of serenity and glory, where it will remain for the admiration of all the coming ages.

Though the world has thousands of fine talkers, clever talkers, cunning, shrewd speakers, where is the immortal for the Halls of Fame? Neither the bar, the forum nor the pulpit measures up to the demands of this age for one who can give a voice a form. So, with poets, many write pretty verses, delightful verses, well-constructed verses, but not immortal poetry. Through all their rhymes run the little wheels of commerce, and in them we hear the jingling of the guinea.

And where is the philosopher to give the world a new system for life and thought? In the past, at well-measured

periods, the philosophers rose above their kind, like mountains out of the sea, and stand today in their empyrean glory, while the billows of commerce and the tides of years surge about them in vain. They created a new world of thought that the world entered into. But search the world as we may, we find but a forest of men, and not a giant philosopher among them rising to the stars.

This is an age of restful dissipation, and voluptuous idleness for the gorged few who live upon the gold coined from the blood of the plodding, toiling millions, for whom the factory gate is the opening to a prison.

Bachelors.—In the United States there are more than seven millions of bachelors and a corresponding number of single maidens of like age. This adds its full share to race suicide.

Seven million families of but three children each, during the reproductive period of woman, from fifteen to forty-five, would add twenty-one million people to our race. If children are the chief object of existence, some means should be found to utilize these bachelors and maiden ladies to add to the numbers of their kind. These unmarried men and women are, usually, of a higher grade in intelligence and education than the average, which has its effect on the intelligence of the nation in retarding it. The presence of more than seven million of mature, unmarried men, adds nothing to the morality and chastity of society, nor reflects much credit upon themselves. It has a tendency to make permanent a system of concubinage, with all the concomitant evils that belong to sexual depravity. It would be better to have polygamy, and let the maiden ladies be plural wives, than as it is. I do not mean to convey the idea that the unmarried women whom we call "old maids," have morals on as low a plane as that of the bachelor. This would be an injustice to a noble class, whose moral rectitude ranks up with the best. The bachelor's paramour is rarely the old maid. She may be a weak girl or a morally unbalanced married nymphomaniac. More frequently, however, it is the hardened siren who makes financial traffic out of the sanctity of womanhood and hope of the soul.

To elevate bachelors, politically and socially, is to encourage an unnatural condition, to the detriment of the home. In choosing between the married man and the bachelor for office, other conditions being equal, we should never consider the bachelor's claims as within the radius of the best interests of all. The representative of a family is the best representative of the people.

Mingling of Races.—In the mingling of the Anglo-Saxon race with the brown Asiatic Mongol, and Malay races, and with the negroes, will come the suicide of the white people of America. Amalgamation is the inevitable result of the mixture of the races. The negro is the most objectionable to the white race, but a far greater number of mulattoes than of full-blooded negroes is an evidence that the barriers of race prejudice is but a frail guard to a large class of both colors.

The objection to intermarrying with the brown races is less than with the negroes, and will scarcely hold back the young white man, always so susceptible to the languorous charms and yielding submission of the Oriental women. To many Anglo-Saxon men the women of our race are too self-possessed and opinionated for a loving companionship. These characteristics are more common in the American women than in her sisters in Europe, and conspicuous by their absence in the brown women of Asia.

The intellectual standard of the American women being so much higher than their Oriental competitors that throng our shores, will also count against them with not a few men of their own color. A man is largely a vain, conceited, selfish bigot in pants, and seldom falls in love with the same type though she does wear skirts. The education of American girls teaches them independence and self-reliance. These qualities, aided by our social system that gives women the liberty to come and go as they please, make them able to care for themselves, personally and financially, quite easily. The necessity for a husband is lessened to a mere convenience and companionship, under this system. Hence, many of the more intellectual and strong-minded women prefer single life. With such, maternal love is comparatively weak, and

children a greater objection than a husband. They are given far more to the mental and philosophical influence of the cerebral convolutions than to the amorous suggestions of the cerebellum. Such remain single from choice, and liye unto themselves.

The superfluous man that now finds his temporary, but not always modest, affinities more numerous than a state of purer morals would suggest, will, in after years, wnen the yellow and brown, and more amorous women, swarm from the Pacific shores, find a wife in the less austere, and less intellectual, and less fair. But even more rapidly will the white women, of the less intellectual type, marry the brown men. In this rushing together of white and brown races a new race will be born. What effect this mingling of blood will have on our western civilization time alone will tell. It is not risky, however, to predict it will turn the hand of progress back toward the hour of more primitive and Oriental life than our blood has known, as yet, on this continent.

The Anglo-Saxon blood that remains pure the longest time during this reign of sexual supremacy will be the highest cast. But they, without the hedge of a monarchy to sustain them in power, will, finally, become victims of the democracy of virility.

The weakest point in the politics of a republic is the tendency to cater to the base and the low, if they have numbers. It is this spirit that threatens our race, as it does our national pride. The mingling of colors and blood will lower the standard of morals, mind and patriotism, and lower the flag of the free. The republic will not long survive the advent of millions of Chinese, Japanese, and other dark peoples from Asia. A government, like a stream, can not rise above its source.

As all the people are the source of government in a republic, ours must be lowered by the mingling with the hordes from Asia and with the vicious millions from the slums of European cities. With more than a million from Europe annually, and of a lower grade, intellectually and morally, than came in past years, to be greatly augmented with each coming year, they alone, it seems, would solve the problem in favor of a monarchy. Add to this unpleasant feature many more millions from that exhaustless forest of human animals, India and China, aided by Japan, Corea, and a due number from the other dark spots on the globe, down even to Borneo, with its wild men, the end of the republic may not be so far off. Add to these swarming human pests the ten million negroes already here, well on the road to amalgamation, and a rough guess would not claim white supremacy to outlive this century.

And thus it seems that fate wills that the greatest and most beautiful picture of humanity, painted on the canvas of truth by reason and faith, shall be spoiled by the instincts of passion.

Exhausted Soil.—The exhaustion of the soil from the heavy drain on it when the over-crowded conditions shall demand a crop every year from every available acre, will be no small factor in hurrying race suicide. Even now, with our present population, which is very small as compared to the millions that will inhabit this country a hundred years hence, is draining heavily upon the resources of the earth.

Millions of acres that irrigation will add to agriculture in the West, will aid greatly in feeding the prospective millions heading this way, and further defer the inequality between lands, resources, and humanity's unwise increase. But, at the same time, the fact of our redemption of millions of fertile acres will invite the swarms of hungry creatures from their homes of want, barren hills and sterile plains. They will come to sap the new world as they have the old. From here they can turn to South and Central America, and devour that like a swarm of locusts would the leaves of a tree. They can go North, until the snow line thins their ranks, to meet the limited food supply. To meet such conditions as these the wisdom, statecraft and the cunning of priestcraft has taxed their wits but found nothing better in Pagan lands than the baby tower or the monster of the Ganges, and the prevention or abortion in Christian countries.

As nature meets all demands upon her, in some way she will in such cases as the future may bring, but never with the

hand of gentleness or the voice of mercy. Pestilence and famine will feed upon the hungry, and sterility deny the weak the power of reproduction, and thus avert the repetition of more dreaded conditions.

Unfortunately, modern transportation disarranges the adjustment that natural forces have made in older countries by bringing their millions to new soil and new conditions, where their dormant virility awakens to run riot. While they do not drop to a lower plane than they and their kind have lived upon for generations, they have more strength to indulge their animal instincts, and do so unchecked by neither the sentiment of modesty or the foresight of philosophy that would lead to a thought for the welfare of their kind.

If science can avert over-production of the human species, along with the many other beneficent things it has done, it will not only save the race untold sufferings, but elevate it to a plane of self-control. To stimulate the soil to increase production, and add millions of acres from idle desert waste, can not alone do this. It must enlighten and teach humanity to limit its birth-rate to the capacity of the bosom of mother nature to feed her children. This lesson can scarcely be expected before the dire calamity of starvation has signaled its necessity.

In all ages the school of suffering alone has taught the wisdom that saves the race, God setting the example with fire and flood, whose flames and waves, even to this day, seethe and surge around the immortal names of Lot and Noah.

Religious Change.—A change wrought in religious sentiment of America, by the influx of the millions from Europe and Asia, will be as great as that in any of the other affairs of humanity. While the zealous Christians will struggle with a renewed zeal and redoubled energy for awhile, the hopelessness of the task will finally be so apparent that fate shall soothe the intensity of over-wrought devotion into placidity of compromising rest.

When Alexander the Great had conquered the seventy cities of Asia, and the storm of Asiatic force had wasted its energy upon the Macedonian's walls of men, it could only sigh into rest from sheer exhaustion and accept the inevitable. Then both necessity and policy opened the way for peace and fraternal relations, which enabled the conquered to accept the boon of Greek democracy the hero brought, and take up the work of scattering it to the world. In doing this, they did not lose the good of Asia, but added the hope of freedom that was destined to liberate others before their own land was emancipated.

This was the result of a superior people carrying a lofty and noble truth to receptive minds; as might be expected, this seed bore fruit that has enriched the whole world.

But when an inferior, mongrel horde overruns a country, and, by almost countless numbers submerges a noble people, and with their debased nature, contaminates their blood, no exalted ideals, such as Alexander the Great's conquest left for the inspiration of the seventy cities. With the pollution of Anglo-Saxon blood to such an extent as the invading hordes would promise, the genius of intellect that has carried the great republic so far above the other nations, would be hushed in the tumult of a Babylon of meaningless tongues.

As deeply to be regretted as a war with the dark Orientals would be, it would still be a far less calamity than the overrunning of our country by the cunning, deceit and degradation of Asia. If only the army and navy can stay the yellow flood, and hold it to the other side of the Pacific, Americans will not be slow in deciding as to the means of protection.

If England, Germany or France should attempt an armed invasion of the United States, to subjugate our country, we would resist until the last man fell with his face to the foe.

And yet, such an invasion would be far less in its evil and lasting effects, though we should surrender and welcome them as our master, than a peaceful invasion of the yellow parasites that creep and crawl from the human ant-hills of the Orient, to swarm over our valleys and plains.

It would be a less evil and less humiliating to be subjugated by a noble race of our own kind, in the carnage of war,

than to be debauched by the beastly virility of the scum and slime of Paganism.

A war with Japan, at this time, might be of untold benefit to our nation and our blood.

Olla Podrida.

BY S. E. MCCULLY, M. D.,
Dallas, Texas.

Sometimes, in a reminiscent mood, the physician's mind wanders over what he has and has not done in his profession, and he begins to sum up facts in treatment, placing in the balance his (olla podrida) mistakes and successes, and suddenly he is aware of what a blind plodder in medicine he has been. Many of us are not to blame for lack of professional sight, for the reason that, at the outset of our professional careers, we will be led into the brambles of theory and there left, too often without compass, or any other mental guide to extricate ourselves. Sometimes I am doubtful as to the methods of teaching medicine in our schools, as now established. I fear there is too much stress placed on branches that (when the doctor leaves his *alma mater*) are of little practical use, and subjects such as the practice of medicine, *materia medica* and therapeutics and obstetrics, on which he must make or mar his reputation, are too lightly treated. There should be a distinction between laboratory men and those whose life-work is to be the practice of medicine. Bacteriology may be, and is, a nice distinctive method of diagnosis, but physical symptoms to the acute observer without a laboratory (and how many of us have a laboratory, or can afford a well-equipped one?) seldom lead him astray. Then, in the early stages of all febrile disorders, the plain and manifest duty of the physician is the elimination of toxins. When the temperature rises to 102° F., then, practically, all elimination ceases; then the blood becomes loaded with morbific poisons often more dangerous to life than the original toxin or "germ" that precipitates the fever. Take pneumonia, where it is very doubtful whether the pneumococcus lanceolatus is anything more than a product of the disease—may be a scavenger; if we believe this micro-organism is the primary cause of the disease, and not a sudden loss of caloric due to great exposure, then it would be the manifest duty of the physician to exhaust every method known in an attempt to reach the bug suddenly turned loose in the system to work his unmolested will; if, on the other hand, we believe that pneumonia of an active form is invariably due to a rapid drop of temperature, that the induced fever is simply a reaction, and that the greater the loss of heat the greater the reaction will be, the more intense the fever, with correspondingly violent symptoms; then our duty is to control the fever, reduce pulse and temperature, leaving nature to work out control of all the bugs and other *materies morbi* that infest the individual attacked by this fatal disease. Long before the discovery of the theory of diseases being due to micro-organisms in pneumonia, I used to give minute doses of tartar emetic, with potass nitrate and Dover's powder from every two to three hours, and got better results than my neighbors; but when I later adopted aconite, gelsemium and lobelia, I never had a case of pneumonia die on my hands, and I invariably get resolution in from three to six days after the attack.

Your medical agnostic will rise up and denounce my cases as only congestion of the lungs. Brother, the next case you get just give specific tr. aconite one drop, gelsemium three drops, lobelia two drops. Make up a glassful in the above proportions and start with it every half hour. Follow it up until there is a distinct slowing of the pulse, and from a half to one degree of fall in the temperature; then give it every hour till the pulse is near normal; then give it every three hours, and continue till resolution is established, and, given an ordinary constitution, you will never again lose a case of pneumonia.

In all febrile conditions, if the physician will control pulse and temperature, the excretory organs will take care of the products of high temperature and suppressed secretion, and while it may be a source of pleasure to make your cultures,

differential diagnosis will not be necessary. Instead of permitting the disease to exhaust the individual by burning tissue, and staying the processes of nutrition, exhaust the disease by opening up the viaducts of the body, and giving nature an opportunity to throw off toxemic conditions. Hundreds of patients die from heart-starvation, due to excessive and uncontrolled rapid contraction. To start with, were it possible for a normal heart to beat continuously for, say, twenty-one days at the rate of one hundred and thirty contractions to the minute, when normal would be, say, seventy-five, and were it possible to do it without febrile conditions, that heart would be in a weak, flabby, starved condition at the end of that time. But with a pulse of one hundred and thirty and a temperature of 103° or 104° F., what must be the condition of nutrition of that heart, as well as every other tissue in the body? We too often fiddle the poor heart; brain and body burns. We fiddle because we are medical agnostics, trained by an agnostic professor whose gray-matter never was illuminated with specific medication.

Lay down the principle in all cases of fever, that a free use of non-irritating antiseptics is good treatment, and where no contraindications exist a flushed bowel generates no toxins. In my life, covering forty-five years of active practice (and I am still a worker in the medical hive), I have attended over one thousand four hundred women in confinement. Of that one thousand four hundred one died from embolism. The rest of my cases made good recoveries except two. They had each mild attacks of septicemia; both recovered. My forceps cases were, all told, nine. Two cases I had where I was forced to remove the bodies in sections—the bones of the skull, the arms, then the legs. In one case the child weighed seventeen pounds when the pieces were placed on the scales. The other was a child of six and one-quarter pounds, and the mother had a pelvis so small that I doubt if a living child weighing two pounds could have passed the arch. A majority of lacerated perineums and cervixes are due to the *hurry-up doctor*. My old obstetrical professor used to tell his class at the beginning of each lecture: "Meddlesome midwifery is bad." Any attempt to use forceps before the head has cleared the cervix is simply infamous, and is almost certain to result in rupture. Brother, before the pain starts have your index finger well up between the cervix and the head, then stretch the cervix by passing the finger around the entire circle, at the same time stretching the cervix freely. By doing this, usually two points are gained: The pains are increased, both in rapidity and volume, and your dilatation lets the head engage the arch, and thus no rupture of the cervix will ever take place. Now, when the head reaches and passes under the arch, wait! Wait! Give it a chance to make and pass the plains till it reaches the perineum. If the perineum is unyielding, use hot cloths, and change, but leave your forceps in the bag. If the perineum will not yield, it is better to cut than to rupture; for you have a surface that will heal immediately, if properly sutured. Brethren, for God's sake, do not strew your life's pathway with female cripples. I never ruptured a cervix, never ruptured a perineum. I resected one, immediately sutured it, and had union by first intention.

Now, a word about skin diseases: Outside the syphilides, reader, did it ever strike you that every form of eczema is a fungoid, is amenable to local treatment, and belongs to the family of vegetable fungoids? If you are a delver into the mysteries of microscopy, here is a field for investigation. Find the fungoid, name it, and photograph it. Take, as an example, a persistent case of eczema capitis, where there is layer after layer of scabs. Just remove the scabs with soap and water, and when all are off that can be removed by that method, start in yourself and clear the scalp of every scab. You will find patches of ulceration, and patches where the skin is rough and scurfy. Now take glacial acetic acid, reduce it by adding an equal volume of water, and treat as many of the sores as your patient will stand by applying the reduced acid with a camel's-hair brush. Do not stint the application. Often one application will do the work; but just watch, and repeat, if necessary. Now

make an ointment as follows: Ol. eucalyptus twenty drops, ol. betul twenty drops, crysophanic acid ten grains, pyrogallic acid six grains, white petrolatum two ounces. Mix the acids and the oils to a consistent mass, then add the petrolatum, and apply twice daily, washing the head with warm water and castile soap. Where in patches on the body, remove the scales and apply acid and ointment similarly. Where you meet up with a case of snowflake eczema, and the whole body is involved, use No. 8 acetic acid, reduced by adding to it an equal volume of water, then sponge the entire body, and substitute raw linseed oil for the petrolatum.

Abdominal Diagnosis.

BY A. W. REDDISH, M. D.,
Sidney, Ohio.

In no field has diagnosis made greater strides in the last decade than in the abdominal region. This is well illustrated by the statements of two eminent surgeons. The first, Lawson Tait, about ten years ago, gave voice to the following pessimistic quotation: "Exact abdominal diagnosis is impossible, and he who will assert otherwise is either rash or inexperienced." The other, Tuffier, a recent author in an optimistic review of abdominal diagnosis, says: "In practice, by minute and methodical analysis of symptoms and of causative data, combined with laboratory tests, you will, in the majority of instances, reach an exact diagnosis, and thereby a rational treatment."

Tumors of the right hypochondrium are of the greatest interest to the surgeon and general practitioner. They will be divided into three groups: the liver and gall bladder; the kidney and the colon and appendix. Always search for the exact seat of pain on pressure for the maximum sensitive point. In appendicitis the maximum point of sensibility is at McBurney's point, but this is not invariable. It may be much lower and be indistinguishable from the ovarian center, and it may shift to the left iliac region. I once operated on a lady for a femoral hernia, and found the appendix in the tumor mass along with the gut and omentum. If the appendix is subcecal or complicated with typhlitis or typhocolitis then the inflammation may crawl up back of the colon, and the dullness may extend as high as the liver and become continuous with the liver dullness. Generally there is a resonant zone between the dullness of an appendicular tumor and that of the liver. The cystic center is at the point where the gall bladder projects itself against the anterior abdominal wall, which is at the intersection of the outer edge of the right rectus muscle and the tenth rib. It is here that we find the maximum painful point in cholecystitis, perichole-cystitis and in cholelithiasis.

An enlarged gall bladder may extend to the epigastrium or descend below the umbilicus, and thus constitute the epigastric or umbilical centers. Radiations or transferred pains may shift the maximum painful point to the inner angle of the scapula to the point of the right shoulder, to the mammary region, or, if it should chance to follow the phrenic nerve, to the right side of the neck, the nape of the neck, or the head. Descending radiations are infrequent.

In gall-bladder tumors the dullness is always continuous with the liver, and however large the tumor may be, the bottom of the iliac fossa is always accessible to the fingers, which is not always the case in appendicular tumors. Wherever the pains may be, the maximum sensitive point to pressure is at the electic spot of the gall bladder. The patient gives a history of liver disease or previous seizures, and the tumor follows the movements of the diaphragm in breathing. The renal center is located between the appendicular center and the cystic center on a level with the umbilicus at a point further out than the external edge of the rectus abdominalis. This anterior painful point is accompanied by pain and stiffness, with rigidity of the muscles in the side and lumbar region. The radiations are downward to the groin and inguinal canal, often going as far as the scrotum, testicle, penis and labia. Pain in the groin and testicle may be met with in appendicitis.

Ascending radiations to the thorax and arm are not common in renal diseases.

Severe kidney pains may produce a functional impotence of the entire side.

The swelling or tumor of appendicitis is located in the right iliac fossa. It is motionless, firm and circumscribed, if there is not too much edema, and separated from the hepatic dullness by the resonance of the transverse colon.

A movable tumor of the appendix without adhesions may resemble a floating kidney, except for shape and direction of mobility. It should be remembered that a floating kidney will slip back into the lumbar fossa and out of reach while being manipulated. When the appendix, cecum, coils of intestines and omentum are agglutinated without adhesions to the parietal walls, perforations are especially dangerous, as general peritonitis will certainly follow.

Appendicitis has been mistaken for coxitis in children. An error may be avoided by a careful examination of the appendicular region, as follows: "Place the hand flat upon the abdomen at the umbilicus, press deeply with the fingers until you can touch the posterior abdominal wall, and then draw the hand slowly toward the anterior superior spine of the ilium, pressing deeply and keeping the tips of the fingers in contact with the posterior wall. The appendix will be felt about one inch exterior to the iliac arteries on the right side." The symptoms of appendicitis, beside those already mentioned, are: tenderness of the appendix, nausea, vomiting, fever, rapid pulse, and constipation. There may be diarrhea. An evening acceleration of the pulse and temperature with rigors, an increased leucocytosis and an increase in the size of the tumor indicates suppuration. Perforation of the appendix is indicated by severe pain, great tenderness, rapid pulse, marked rigidity and shock.

In hepatic, perihepatic and cystic tumors the dullness is continuous with that of the liver, and they rise and fall with the diaphragm in breathing. Hydrated cysts of the lower border of the liver have these characteristics, unless they are connected by a pedicle, when they are motionless and might be mistaken for a floating kidney or an appendicular tumor that is not adhered to the abdominal wall. In pure hepatic colic due to lithiasis the onset is sudden pain, acute in the cystic center over the gall bladder, with upward radiations, vomiting first of alimentary and then of bilious matter; sweating, thready, rapid pulse and depression with pyrexia, if infections and suppurative icterus is present, if a calculus obstructs the choledochus. These attacks are prolonged, interrupted by periods of calm and accompanied by nervous symptoms. When the calculus drops into the duodenum the seizure comes to a sudden end.

In the diffuse variety the swelling may extend down to the iliac fossa and might easily be mistaken for an appendicitis, but soon the edema of the omentum and of the colon disappears, the tumor becomes circumscribed, rounded, elastic and smooth, perhaps fluctuates, and it rises and falls with the diaphragm. It has become vesicular. Like intermittent hydronephrosis it may disappear by the voluntary discharge of its contents, and it may vary in size. When a well-fitting calculus at the neck of the gall bladder acts as a valve, the vesicle may become enormously distended by the valve permitting the inflow of bile but permitting none to escape. Such tumors may extend below the umbilicus and be mistaken for ovarian tumors. Sometimes these tumors become inflamed, adhere to the abdominal wall and discharge their contents externally. If the contents of the gall bladder remain aseptic, nature may obliterate the viscus by absorption of the contents and atrophy of the vesicle.

Peritonitis and shock, without any apparent cause, with a history of chronic cholelithiasis, may be caused by a calculus ulcerating through, permitting the contents of a septic gall bladder to discharge into the peritoneal cavity.

According to Courvoisier's law, when the common bile duct is obstructed by a stone the gall bladder does not enlarge, but when the obstruction occurs from other causes enlargement is generally present. Complete obstruction seems to inhibit the function of an organ and atrophy of its viscus.

Impaction in the common duct produces jaundice and catarrhal cholangitis. In catarrhal jaundice the pulse is generally slow—from twenty to forty. In severer obstructive forms it is rapid. In case of

infection the suppurative form develops with chills and intermittent fever.

Tumors of the kidneys are reniform, smooth and rounded on the lower edge. The upper edge can not be outlined as it disappears beneath the ribs. They are lumbo-abdominal and are felt in the lumbar fossa. By bimanual palpation they can be easily examined, as they slip about between the hands and drop back suddenly into the fossa again out of reach. They lie behind the colon, which is resonant on superficial percussion. In large renal tumors the colon is pushed outward and the tumor then comes in direct contact with the anterior abdominal wall. Hydronephrosis is a typical, large renal tumor. In the intermittent variety the attacks come on suddenly and periodically, without warning and without connection with the meals. The patient is suddenly seized with pain in the renal center, with downward radiations to the groins, labia and scrotum. A tumor appears in the region of the kidney that was not there before. The patient is rigid in a fixed position, leaning forward or to the affected side. Oliguria, anuria, slight hematuria and bilious vomiting may attend the attack. Suddenly the kidney may become mysteriously untwisted or the manipulations of the physician may set it right, when the attack comes to an end, the pain ceases, the kidney resumes its normal size and shape and only the floating kidney remains to remind the patient of his terrible suffering. The polyuria, which now appears, is attributed to the twain causes of vesical crisis and to the untwisting of the kidney. Cicatricial bands may cause progressively enlarging tumors in the renal region. A calculus may produce hydronephrosis by obstructing a ureter, but a permanent obstruction is not as liable to produce hydronephrosis as a partial or temporary obstruction, because a permanent obstruction tends to produce a cessation of function of the kidneys. The diagnosis of renal calculi is to be made by the presence of pain of a sharp, sticking character, or by a dull aching pain deeply seated, located at the kidney center. The pain may last from half an hour to several hours or longer, with more or less suppression of urine and profuse sweating, by the presence of pus and blood in the urine, in some cases by hydronephrosis if the obstruction is complete and by finding a calculus in the urine after the attack. Before making a urinary examination wash out the bladder, wait a few minutes and then get a specimen of the freshly secreted urine. The Röntgen ray, in the hands of an expert, may be an aid in diagnosing renal calculi. The first symptoms of renal calculus are pain, sudden, severe and continuous in the renal center, with soreness in the kidney region. The pains may abate and come again with renewed severity, vesical irritation, blood in the urine, concentrated urine, crystals of oxalate of lime and uric acid. The urine is acid and of high specific gravity. After an attack the calculus may be found in the urine; hematuria is slight and may be absent. It is never as large nor as persistent as in tuberculosis of the kidneys. The urine may be suppressed by an occlusion of one ureter by a calculus and by spasmodic contraction of the other.

In renal tuberculosis the onset is insidious, but the pain will be sudden if the ureter becomes occluded by a blood clot or by cheesy material. Usually the patient complains of a dull pain in the back, vesical irritation, painful and frequent micturition, early increase in urine, later diminished. Morris claims that polyuria in a frail patient with a tubercular family history, for which no adequate cause can be assigned, should excite our suspicion of renal tuberculosis. Hematuria is an early symptom and pyuria is almost invariably present. The blood is well mixed with the urine, which is acid unless cystitis coexists. Hemorrhage may be copious and persistent. Albumen is present and perhaps blood casts. There is an evening rise in temperature, loss of flesh, anorexia, pallor of skin, night sweats and the presence of tubercle bacilli in the urine. The physician, however, should diagnose his cases before this typical array of symptoms make their appearance, unless he wants to appear dull and stupid. The symptoms which will guide us in the diagnosis of renal tuberculosis are: Pain in the kidney region, not so severe as that resulting from calculi, coming on slowly and gradually, as a rule; dysuria, polyuria,

hematuria, pyuria, acid urine and the presence of albumen, tenderness along the ureters, tubercle bacilli in the urine, which are not due to bladder and prostatic tuberculosis. The disease is chronic and may manifest itself as a pyuria for many years without occasioning much discomfort.

In malignant diseases of the kidney a tumor mass may be made out which increases in size rather rapidly. Hematuria is the most important evidence of the disease. There is a sense of weight and discomfort in the kidney region. In simple suppurative pyelitis, pyuria is the chief symptom, and pus, sometimes accompanied by blood, appears in an acid urine. If the ureter becomes occluded pus collects in the pelvis of the kidneys, producing a considerable tumor. If the patient has been suffering from cystitis with pyuria and alkaline urine, and the symptoms should suddenly change, the urine becoming acid and profuse, with heaviness in the lumbar region, a suppurative pyelitis has developed. If the urine is clear of pus it has become obstructive, and chills, followed by fever and lumbar tenderness, may develop. A movable kidney, during bimanual palpation, slips about like a loose pea in a pod. It may be pushed as low as the umbilicus, and then it evades the palpating fingers and it drops back into the lumbar fossa again. The symptoms produced are a dragging sensation and a general feeling of weakness, dyspepsia with sensory motor and secretory neuroses of the various abdominal viscera. Painful crises, mucous colitis, hydronephrosis from kinking or twisting of the ureters and intermittent albuminuria.

Edebohls says that chronic appendicitis is the chief symptom and most important complication of movable kidney. A floating kidney may be found anywhere in the abdominal cavity, so if a kidney is missed from its usual site search should be extended through the entire cavity for it.

Tumors of the sub-hepatic angle of the colon are generally neoplasms. The symptoms are diarrhea or constipation, bloody stools, melena and a fixed tumor in the sub-hepatic flexure of the colon. If the tumor should be movable in the early stage the diagnosis offers more difficulties, and if it should manifest itself only by slight attacks of obstruction, the diagnosis may be less certain. Carcinomatous rings may form and give rise to only slight symptoms of obstruction, but inducing abscesses. Tuffier says "beyond the age of fifty all acute intestinal obstructions are due to cancer." A contracted intestine, due to muco-membranous enteritis, may produce a tumor. Their relationship to the colon may be traced, for they are movable transversely only. To the palpating fingers they feel like hard cylinders, and they may be found in the sigmoid as well as in the ascending colon. During periods of calm they are dilated, relaxed, filled with liquid, and they splash on palpation, but then the painful crises return again and with them the transversely movable cylinders. These tumors, along with floating kidney and uterine prolapses, all belong to that class of diseases called ptosis or enteroptosis.

In ordinary gastralgia the pain is in the middle of the epigastrium and radiates to the left. There is neither fever nor jaundice. In enteralgia or intestinal colic the pains are in the midabdomen; they are relieved by pressure and by the passage of flatus. Many more conditions might be differentiated, but this paper is already too long. Much is yet unknown; nothing is unknowable, and a positive diagnosis will generally reward the methodical analysis of symptoms and a study of causative data.

Pneumonia.

BY GEORGE ROBERTS, M. D.,
Lincoln, Va.

For the benefit of your readers who, like the great Osler, say that pneumonia is a self-limited disease, and for which there is no remedy, will cite a case:

Mrs. S., temperature 105° F., pulse one hundred and thirty, in the fourth month gestation, aborting, membranes protruding, absolutely without labor pains; cough incessantly, very dry and rasping; hurried breathing pains in lungs; tongue coated, and vomiting bile. I gave ergot, which was vomited at once. Then decided to direct all treatment to the congestion

of the lungs; gave some calomel and acetanilide, in small, frequent doses, not weighed or measured, to move the bowels. I then put one-quarter teaspoonful each of the fluid extracts of aconite, veratrum vir. and digitalis in three-quarters of a tumbler of water. A teaspoonful of this was taken every hour until sweating occurred.

I called next morning: fever gone; bowels moved twice; temperature normal; no pains; light cough, expectorating rusty sputum. This was at 10 a. m. Left to make another call at 12 m. While away the labor pains came on, and delivery accomplished without further trouble. Returning in the afternoon, found patient comfortable, and recovery uneventful.

All deviations from health are now said to come from faulty "metabolism." This is a modern word not found in medical dictionaries forty years ago.

The majority of cases of sickness are due to auto-infection from the alimentary canal. If this were not so the various patent medicines, pills and purgative bitters would not flourish as they do.

Realizing this fact, it is our duty as medical attendants to clear out the alimentary canal first of all. Nothing answers this purpose as well as small doses of calomel, repeated to effect. A favorite combination of mine is with acetanilide.

I always do my own dispensing, which brings patients back to me when in need of anything. A few powders of calomel and acetanilide turn many a case of sickness. One night a man called, said his girl was passing blood from the bowels. How old? I asked. Fifteen, was the answer. Thinking it fifteen years, I put up six powders at random, containing each from one-half to one grain of calomel, with five or more grains of acetanilide, to be taken one every hour. The next day I was called to see another one in the same family. After attending this patient, I asked where the sick girl was. Imagine my surprise when told it was the fifteen months' baby playing in its crib, apparently well. The mother said she gave all the powders, and was so much pleased with the quick relief, sent for me to see another. This shows what large doses of these drugs babies can stand, but it is not my way, and now I am careful to note the age. When in doubt as to the nature of the complaint, I take from a stock bottle a solution containing epsom salts and sulphate of iron, a teaspoonful to be taken in a tumbler of water after meals. No therapeutic nihilism for me. I know the value of drugs, and use them.

In Compliment to Dr. Rose.

Dr. Julius Bartsch, of Lüneburg, Germany, writes as follows in reference to Dr. Rose's memorial on medical language, published in THE MEDICAL BRIEF, November, 1907:

"In my opinion it is a great testimonium paupertatis that the great medical coryphei have failed in the construction of a logical and scientifically correct nomenclature for the designation of their own epoch-making discoveries. Medicine is creating constantly new conceptions, and for whatever new it creates it requires new appellations, and this to such far-reaching extent as to render the resources of a dead language inadequate for the expression of meanings in exact sense. Thus the custom has been acquiesced in to attribute to a number of words certain interpretations which originally had a totally different meaning. The German schoolmaster had his share, which is not to be wondered at, he being about the best fitted for the task, but, after all, a schoolmaster is but a schoolmaster—not competent to interpret medical terms. On the other hand, the Greek is a logically and distinctively expressive language, and, ancient though it is, is a living idiom, and, therefore, capable of evolution. If, then, Greek philologists are able to bridge over the gap between ancient expression of thought and the linguistic rendering of modern conceptions—a point on which I am not sufficiently competent to pronounce an opinion—then Greek is the language to draw upon. All these arguments do not apply to Latin."

The Missing Link in Medicine.

BY L. HERBERT LANIER, M. D.,
Aurora, Mo.

How could there be a missing link in the healing art? When we consider that there is today so many people engaged in healing the sick, or who profess to know of certain herbs, roots, leaves, mixtures or medicines, the administration of which will surely relieve any disease human flesh is heir to.

And if, perchance, some afflicted individual, by reason of idiosyncracy, was not cured of his disease by the numerous relatives, all of whom pretend to know of specific remedies for all diseases, then there is no use to suffer longer. The Christian Science healer has offices around the corner, and is ever ready, for only two dollars, to come and tell the patient that there is nothing material, except mind (their fee excepted), and that he only imagines himself to be sick and in pain, though it will take twenty visits at two dollars *per* to get this morbid thought eliminated from his mind.

This particular patient, however, was suffering severely with acute inflammatory rheumatism, and after trying his best to think all was mind, and that he had no disease or pain, he was forced to come to the conclusion that the mind-healer was mistaken, and that he had feet, limbs, muscles, swollen joints, high fever, and much pain, and that he would try a practitioner of medicine.

Therefore he sent for Dr. B. The physician arrived, examined his patient, and left one bottle of medicine. Directions: Two drops every four hours, and some little microscopical granules, one every six hours. The patient continued to take this, and the physician continued to call for three days, and the patient grew gradually worse, and upon inquiry, found that his physician was from that school that teaches infinitesimal doses.

A physician from the regular school was called, and examined his patient, and, of course, regretted that he had not been called sooner, as this dangerous disease had progressed until heart complications made his chances for recovery one in one thousand.

This physician administered some drugs which were indicated, and did some good, though "a chain is no stronger than its weakest link," and when he gave the commercial article of sodium salicylate, instead of sodium salicylate from the true oil of winter green, he made an unpardonable error, and failed to cure his patient. The patient, however, was able, after a few weeks, to be out, and after giving several physicians a chance to cure him and restore the function in the stiff joints, and after all of them had used iodide of potassium, and other alteratives, instead of giving him a course of treatment and curing him with the modern mechanical appliances which we have today, his stomach was filled with nauseating drugs, and he received no benefit, and decided to try an osteopath.

As usual, the bone doctor found that the third lumbar vertebra had been dislocated since infancy, and was causing all the trouble, and he at once began to pull, roll and rub, and did this daily until the patient, for lack of any more money, houses and lots, jewelry or other necessaries, told the bone doctor that he had not been benefited, and would go to the springs when he obtained more money.

Unfortunately, this crippled specimen of humanity came into possession of considerable wealth at this stage of the game, and away he goes to the great cure-all, the Hot Springs, and after several months there we see him back again, no better physically, but relieved financially.

He is still searching for a cure, and as he strolled down the streets one day he heard the voice of a great benefactor, a man working solely for the pleasure there is in uplifting and helping suffering humanity; a man whose smile was so captivating that he unconsciously drew near him; a man who announced, from a goods box, that he was actuated to come to that town because he had heard of the many sick and afflicted there, and that while the physicians did not like him, he intended to do his duty. He could make the blind see, the crippled walk erect, the deaf hear; and cure all diseases in the dictionary of pathologic phenomena. This

generous hearted man said he proposed to do this by giving to the public, at cost, a bottle of Dr. Jones' "Elixir of Life."

We see our crippled friend who was disappointed with physicians, mind healers, osteopaths, and all other healers, force his way to the great man, and buy some of his "Elixir of Life." The ball was now rolling, and hundreds of others crowded up and purchased this "dope," which cost less than the bottle and label around it. After selling all of this infernal stuff, the fakir leaves for another town, where he has had a fresh supply shipped him, and little does he worry about selling it, for he knows *human beings are fools ever.*

What else could our crippled friend do? He was disappointed with his bottle of "Elixir of Life"; in fact, no better. To be sure, his local druggist advertises the very thing he has been looking for: The medicine which it is claimed cheats the grave out of thousands each year. Oh, what a euphonious *lie!* This nostrum composed of water and a weak solution of aromatic sulphuric!

The druggist, however, usually has some ten or a dozen relatives who have been saved by it, therefore, our friend is easily influenced to buy six bottles for five dollars. We find the purchaser, however, returning in due course of time to tell the druggist that the ———— did no good, and that he was going to write to Dr. W. for ten dollars' worth of his absent treatment. And here we lose sight of our friend, while he is in the hands of the king of all fakirs.

Now, who is responsible for this man's wretched condition? First, he is himself, for not calling a reputable physician when he first noticed symptoms of rheumatism, instead of trying to beat some well-meaning physician out of a small fee. Secondly, the responsibility should rest upon the heads of the legislators all over this country who have recently passed laws requiring physicians to pass a rigid examination before they can practice, allowing osteopaths, midwives, mind-healers, magnetic healers and laymen to practice without any examination, as well as old physicians who quit the plow-handles and went to practicing, and only know a few things by experience.

I do not care how rigid the State Board examinations are, but I can not see why physicians should pass them and the other so-called healers are allowed to go unmolested.

The new fangled healers offer to treat their patients for less than the regular physicians. Why? Because they have been to comparatively little expense in getting ready for treating patients, often only renting an office and putting in a little second-hand furniture and assuming the name, Doctor, as hundreds of old physicians all over this country have done until recent years.

It is easy to see why an old physician, who never attended lectures at a medical college, can work for comparatively nothing when we consider that the up-to-date physician of today has to spend not less than five thousand dollars for schooling, hospital training and equipment before he can locate to compete with the healers of all classes, who have been getting acquainted while he was away spending money and time in acquiring knowledge that will enable him to scientifically treat his patients.

And who will the public patronize? The majority will patronize the man who offers them something for nothing (and usually they get nothing for something). The uneducated, so-called doctor, puts in every leisure moment on the sidewalk, or in public places, trying to make himself conspicuous, or trying to make new acquaintances, while the up-to-date physician is reading the latest medical journals, or working in his laboratory over his microscope or test tubes.

The medical profession is not what it should be. First, because there are too many physicians (one hundred and thirty-five thousand) in the United States, and twice as many healers of other kinds, all struggling to make a living out of the public, and the public, in turn, running after false gods and patent medicines, instead of patronizing the limited number of physicians who are endeavoring to elevate the profession above greed and commercialism.

There are a great many things that physicians are guilty of that would cause them to be ostracized and hated by the public in general if the public could only know of them. For instance, if a few middle-aged or old physicians have been doing the majority of the best practice in a town or city, they will mutually agree not to consult with, recommend or mention the name of a young physician, under any circumstances. *Why?* Because they know that there has been a marvelous advancement in recent years in the science and art of medicine and surgery, and they know themselves to be intellectually inferior, so far as therapeutics is concerned, to the man who has recently completed forty-five branches in medicine, when they only had a smattering knowledge of twelve, and they do not want the public to know that some one else knows more than they.

The older members of the profession will sometimes condescend to say that if that young man lives he will be a good physician some day, giving themselves time to live to an old age and die before they think the young man will amount to much. Fortunately, the public is thinking differently these days, and the young, progressive physician is doing most of the work.

The trite old saying: "That united we stand, divided we fall," is as applicable to the medical profession as any other. Yet I would rather attempt to reverse the course of the water at Niagara Falls, regardless of the law of gravitation, and force it toward the heavens, than to try to get any dozen physicians in existence to entertain the same ideas and opinions on any given subject.

Therefore they are divided; there is a missing link, and had they been united there never would have been any demand for the dozen different kinds of healers that are proving such a detriment to our country by sowing the seeds of discord and discontent, and by trying to reverse the laws of nature and science, and increasing their bank accounts at the expense of the medical profession and the ignorant public.

The physicians themselves have done more than any one to cause a demand for those who practice osteopathy, Christian Science, faith cures, etc., first, by trying to treat all chronic diseases, tuberculosis, rheumatism, catarrh, skin diseases, kidney diseases, chronic liver and stomach diseases, piles, fistula, genito-urinary diseases, asthma and diseases of women, and every other chronic disease by constantly administering drugs which only serve to disorder the patient's stomach, and eventually drive him to some healer who does not use nauseating drugs.

Now, do not understand me to say that I do not believe in drugs. I do believe in drugs in acute diseases, but their sphere of usefulness is very limited in chronic diseases, and not until the physicians become educated to use electricity, superheated air, vibration, oscillation, phototherapy, hydrotherapy, suggestive therapeutics, and various other modern methods, will they be able to cure their patients and keep them out of the hands of ignorant, so-called healers of all schools, who never tire of directing the most malicious lies at the medical profession and their work in order to increase their own income.

There are physicians who are not in the profession for the honor that might come to them from a well-spent life in the practice of medicine; such men are often closely indentified with political cliques, and usually are not very well educated. We find them in our State institutions for the insane, members of the State Board of Health, prison physicians, dispensary physicians, on the staff of physicians and surgeons of our large city hospitals—the physician with the best political pull always obtains the place.

Then there is a class of physicians who will lie about things they know nothing of. If some scientific and progressive doctor makes a statement that he can obtain certain results in certain cases by employing certain measures, unknown to the uneducated man, straightway he tells all his patients that the claims of the scientific man are false, and that he is simply trying to make a show for financial gain.

This sort of jealousy has retarded science and modern medicine more than any other thing we can mention. Indeed, "a little knowledge is a dangerous thing."

Just a word concerning the attitude of physicians toward the doctor who advertises. They go into the medical society meetings and all join forces to fight the man who advertises his business, and all claim that he should be classed as a fraud; and just here I want to say that I have spent a great deal of time and money investigating the methods of the physicians who advertise that they are skilled in the treatment of certain diseases, and only in a few instances have I found that they purposely defraud the people.

How is it that some physicians claim that another has no right to advertise his business, yet they patronize, and always try to remain friendly with the druggist who uses half of the daily papers telling the public that there is no use to call a physician, they have drugs that cure everything from ingrowing toe nail to epithelioma. Now, the physician knows the druggist advertises a lie, and that his medicines are worthless, and he also knows that the druggist will prescribe for more people each day than any three doctors who patronize his store. The druggist of today rarely ever tells a patient that he had better see a physician, but he does prescribe and practice medicine without a license.

Then the ethical physician advertises by keeping on good terms with the reporters of the different papers, and getting in all the complimentary notices he possibly can. I know of two physicians who are members of faculties of two reputable medical colleges, who never lose a chance to voice their sentiments against the advertising physician; yet these same men do nearly all the operations for all the advertising physicians in a large city, and they consult with them, and solicit their work—the Dr. Jekyll and Mr. Hyde in medicine.

It is true that the title, Doctor, does not signify what it should; and it means less every day, since opticians who quit plowing and go to fitting glasses assume this title, and since veterinarians, osteopaths, corn doctors, herb gatherers and midwives, all without any feeling that they are intruding upon the rights of others, desire to be called Dr. So-and-So.

And while this is to be regretted, it should not serve to cause the educated, refined and scientific physician to part with those noble traits of character which can only be preserved by constantly keeping in mind his duty to his patients by first acquiring all the knowledge of all the diseases he possibly can, and secondly by equipping himself with everything that will alleviate suffering humanity, and not do it with an eye single to the financial side of the question, but because there is honor there when honorably done.

The missing link can only be supplied by the earnest co-operation of the members of the medical profession with the legislators of each State, in drawing up and enacting laws that will put all who practice the healing art on an equal footing, and laws that will require all who propose to heal the sick to undergo a rigid examination on those subjects, without a knowledge of which they can not accomplish any good.

If this paper serves to cause some physician to change from the galenical pathway in medicine, and step up upon the broad, expansive field of scientific research, and endeavor to elevate the art and science of medicine and surgery to its proper realm in the history of the medical world, then I will feel that my efforts to encourage a much-needed reform is seen and appreciated.

[Written for the MEDICAL BRIEF.]

Pathogenesis.

BY S. B. MUNN, M. D.,
Waterbury, Conn.

The revival of the theory of microorganisms as the cause of disease is perhaps the most significant fact in the medical history of the last half century. There is not much connected with it that is new, although, with the perfection of modern microscopy, we have been enabled to expand the details to an unlimited extent.

Itch, carbuncle and Asiatic cholera were long ago attributed to animalculæ, and the army of pathogenitists divided into two camps. One party taught that the air was full of the germs or spores, which

disseminated disease, and that various vegetable and animal substances contained them in an inactive condition.

The other, with equal pertinacity, insisted that there was an inherent force or principle in everything which, under favorable conditions, would develop itself in organisms of one grade or another.

The controversy was carried on during the eighteenth century between such men as Spallanzini and Bonnet on one side, while Buffon, Needham and others argued in favor of what is often termed "Spontaneous Generation;" that there was a production of newly-organized beings, without parents, their original elements being from the organic material which took form by the operation of the principle of life which pervades everything. For many years these inquiries and controversies seem to have fallen into desuetude, but about the middle of the past century they have been resuscitated and brought forward with greater zeal than before.

The literature is of itself sufficient to fill a common medical library, and the conflict over the subject is as irrepressible and fiercely waged as though the existence of the universe was involved in the issue. Great names have been cited to sustain the doctrines, as well as names that have become great solely from advocacy of it without other particular merit. The former infusoria have given place to bacteria, vibrios and numerous races of cocci; then came bacilli, spirillae, and, finally, all merged into the all-embracing designation of microbe. Hoffman declared them vegetable growths, and made the attempt to classify them, so that the germ theory might have the claim to be called after modern usage, scientific. Dr. William Budd, of Bristol, England, appears to have been the first to promulgate the notion that infectuous diseases were caused by these low organisms invading the body.

This was in 1849; since that the endeavor to develop and propagate the "germ theory of disease" have been assiduous, until the hypothesis has almost become a dogma. Koch, in Germany, and Pasteur, in France, have expanded it and carried their conclusion to the verge of absurdity. They have given us the comma-bacillus for cholera, the anthrax bacillus, the micrococcus for tubercle, and various microbes for fevers, pneumonia, erysipelas, septicemia, etc. They profess to be able to transmit these various diseases by inoculation, and taking their cue from Jennerism have also proposed to arrest or mitigate them by infecting healthy persons. How these bacilli get into the body to do their deadly work has been the occasion of many a fine-drawn theory. It has been supposed that they are drawn in by breathing, also by means of the food eaten. They are said to get into the circulation by the thoracic duct, the pulmonary artery and the various glands. We seem to be hardly safe anywhere; we can neither eat nor drink, breathe the air or perform the common offices of life without mortal peril. Indeed, if this germ theory were true, the fact that the human race has existed on this earth for thousands of years would be incredible. Mankind would have been exterminated by microbes in two or three generations.

The dealers in proprietary medicines are taking advantage of this craze to advertise their wares. Germicides are offered for sale on every side; every new coal-oil fabrication is described as sure to kill bacilli.

The troops that were stationed at the quarantine station of New York in the late cholera scare, had a vivid sense of the absurdity of their employment. "We are here," they used to remark, "to catch the microbes." Dr. Joseph Thomas, after an exhaustive review of the theory, and setting forth of the numerous experiments by which it was sought to be verified, remarks, that in non-infected subjects no bacilli have been demonstrated at the supposed points of entrance into the circulation. This is very significant of the lameness of the theory. "The conclusions which have been drawn by Dr. Koch, and more so by his followers," says Dr. Thomas, "are exceedingly positive." But he adds: "Although the minds of so many individuals are positively made up as to their truth, yet, undoubtedly, it will be possible, only after a long time, to show their truth or falsity. Some of their conclusions are hardly warranted by their researches, and others seem unscientific; however, much of truth is contained in other inferences."

This statement expresses the attitude which the men sustain who are regarded as standard authorities: that the theory is plausible but "not proven." For one, however, I am convinced that no very long period will pass before sensible observers and reasoners in the medical profession, of whatever school, will regard this microbe mania as a mere "fad," one of the little systems that have their day and then exist no more. The fact that the same variety of microbe will occur in large quantities in the tissues and discharges, that they will produce a similar disease when transferred to other subjects, that they will do this when carried by "pure cultures" through several generations, though plausible arguments for the theory, are by no means conclusive.

It is a fact that more than one variety has been found in about every morbid condition which has been observed, and the observations thus far have not absolutely determined which shall be considered the mischief-dealer.

In regard to the production of disease by transferring microbes from one to another, there is reason to believe that it was not the microbes that created the new disease, but the poisonous material that was carried with them. In regard to what are denominated "pure cultures," the fact is that they are only relatively so. A portion of the morbid substance in which the microbes are found goes with them when cultivated, and it is just as proper for us to presume that that also as well as microbes is propagated. It is assumed that only the microbes, and not morbid matter that is with them, increases by the culture, but it is only assumption without proof. Professor Pettenkofer has been for many years engaged upon observations and experiments to determine the cause and mode of dissemination of the Asiatic cholera.

He first determined that the epidemic was diffused by the excreta of patients which had the baleful power of rendering other accumulations of excreta equally morbific and diffusive of the disease. The organisms were duly scrutinized and reported upon, but since the first investigation they seem to have passed out of notice and a new set have come upon the stage. In fact, the investigators seem to have had different results, leaving the friends of the theory as much in the dark as ever. Dr. Koch, traveling in the East, found the comma-bacillus in the water-tanks, and pronounced it the probable disseminator of cholera. It will live and grow in milk, serum or gelatine. Yet the success of his experiments has not much elucidated the matter.

Both Professor Pettenkofer and Professor Emmerich have been conducting a series of experiments. They have swallowed prodigious quantities of cholera bacilli without success. In their case the microbe was a total failure. They have been forced to the conclusion that local and not individual conditions engender the epidemic. The conclusion is a sensible one, and agrees with the teaching of the ablest of the old writers on pathology.

It was a great step when it was demonstrated that cholera was not the result of contagion; and it will be another when we become really intelligent and less given to conjecture upon the agency of these germs and microbes in the relation to diseases of any character. It is evident that disease is the outward manifestation of a disturbance of the physical economy, and that the peculiar organisms found in diseased and dead bodies are results of the condition and not the cause. The notion that cholera, small-pox, yellow fever, scarlatina, diphtheria, measles, etc., are contagious because they occur epidemically, is far from being a fact conclusively established. The occurring of a zymotic disease like scarlet fever or diphtheria in several cases in a family, or several families living near each other, no more shows it contagious than if they all had a common cold. Physicians attending such patients seldom contract their disease, or even convey it elsewhere. Nurses generally appear to be exempt. Indeed, there is often less mortality in a district where an epidemic is raging than at other seasons.

In regard to microbes I do not question their existence, but I do dispute the notion that they are sources of harm. It has been computed that a million of them exist in each drop of milk. The number in a gill or pint, at that rate, would be many billions. If they have any office,

it is to carry and sustain life and not to destroy it.

The same thing may be said of the innumerable invisible gnomes of the atmosphere; there is no good reason whatever for setting them down as foes to life; rather they are its sustainers. In the order of nature, every living thing is nourished from other living substances; we eat the fruits and seed of plants because these contain the highest life-forces, and so are best adapted to recruit our energies. If the various micro-organisms exist in the food we eat and the air which we breathe, then we are fairly warranted in believing that they are in some sense our sustainers, as nourishing our bodies and adding to our vital force; their office and agency are for our benefit and not to our harm.

True, there will be a demur on the ground that the fluids in the bodies of the dead are swarming with micro-organisms, and that the secretions of the bodies of the sick are infested with minute structures not found with those in health. These, it will be insisted, are the agents of infection. We question this very decidedly; because we find the worms of the charnel in the decomposing corpse and the numerous scavengers devouring the remains of a dead animal, we never infer that these creatures caused the death of man or animal. We only look upon them as agents in the wise provision of nature to remove what would be noxious and deadly from where it would endanger life. Many of these supposed agents of infection have no power to propagate their own kind. They are enabled, through warmth and moisture, to absorb oxygen energetically, and so to hurry fermentation to the fulfilling of its appointed function. They belong to the process of decay, and have no special agency to go beyond that. According to Karsten, "they appertain neither to the animal nor to the vegetable world, their mission being only to contribute to the promotion of putrefaction and disintegration like all septic bodies." They are only the companions of death. From the known facts of their natural history we are warranted in regarding them not as the seeds of fructification of special diseases, but as simply constituting material which, in combination with other fermentable substances, undergo septic and regressive actions somewhat like those of urea in combination with albuminates or plasma.

The so-called contagious diseases have been known repeatedly to break out as if spontaneously. There was, a few years ago in Russia, a sudden change in the weather to severe cold, and many thousands were taken down with influenza. The microbe was evidently very busy at that time, if one must be insane enough to interject the theory on that occasion. Small-pox has broken out again and again, even in mid-ocean, without any traceable source for infection. There are like records of scarlatina. Dr. Austin Flint declares that diphtheria is eminently an epidemic disease.

The celebrated Tresseau and Dr. Peters inoculated themselves for it without effect, and Dr. Peters went so far as to apply the virus to his throat. Florence Nightingale witnessed cases of small-pox at Scutari originating without contagion, and one disease merging into another. The late Dr. Carl Spinzig cites numerous cases which fell under his observation, and adds: "Such downright contradictions can not be consistent with the supposition that even a shadow of truth is in the doctrine of so-called infection.

"In nature there is no arbitrariness; all processes are the necessitated phenomena of the operations of unalterable laws; hence, simply from logical inference, the proof is obtained that there can be no infection, and, consequently, the occurrence of the so-called contagious disease is dependent upon a different cause, of which the laws are those that are common to all other phenomena."

With these sentiments I am in accord. I believe that atmospheric and epidemic conditions are essential causes for the prevailing of epidemic diseases. Where these conditions do not exist, or where they exist in only a qualified extent, there will be no epidemic.

The same conditions which develop a disease at one time will develop it at another, whether it be sporadic or epidemic, and the type will depend upon the climate and other conditions. Every epidemic, however like in classification to others, will always exhibit differences at

the various periods of recurrence. I believe, aside from the venereal and some skin diseases, as the itch, there are but two causes of disease. First, some internal ferment, producing some morbid material, and second, atmospheric conditions.

Surrounding physical causes determine the line of demarcation between healthful and morbid action, and by the energy of their operation in the respective season and at the respective locality, give to the prevailing epidemic its specific character. Small-pox, scarlatina and the other exanthematous diseases, generally pertain to cold weather; intestinal diseases, as a rule, are peculiar to hot climates and hot weather. Every season has its prevailing epidemic influence which rules the type of the complaints then prevailing, and when the season and the epidemic influence change, the diseases change with them. Such has been the history of the world. Even when the epidemics rage with the greatest apparent severity, only the weak, those the integrity of whose bodies is impaired, are liable to the attacks; those really healthy are very certain to go unscathed.

They need but to take heart and banish fear. To such an extent is this known to be the case, that it is becoming a common observation that during many epidemics the current complaints are prone to take a type analogous to that of the epidemic, and the aggregate of deaths is often actually less than at other periods. This is usually the case when small-pox is about, and it has been sometimes so when cholera prevailed. We have much to learn of the philosophy of epidemics and their office in the world, far, wide and remote from what has been supposed.

Before dismissing the microbes from their place in modern pathogenesis to their proper abode, it may not be amiss to note some of the absurdities which some of the microbiologists have let themselves entertain. A few years ago the wearing of the beard was denounced as affording a shelter and breeding-place for the germs. Doctors, it was said, were liable to carry diseases from house to house, from having domesticated microbes in their beards. This proposition proved too absurd for common patience.

Then came an onslaught upon kissing. If a mother caressed her babe, she was likely to set some microscopic rascal at its vitals. The young men and young women were also notified of the frightful perils of osculation. The girls were told of the virus, the contagious matter, the micro-organisms that were lurking on young men's lips. It seemed, however, to have excited curiosity rather than alarm. They could not well resist the temptation to know the good and evil. They generally seem to have found no other evil; no microbes or contagion, except that they were prone to the infection of a desire to repeat the experiment. The young men were also desperate enough to incur like risks. I forbear any attempt to speculate upon the matter, and the registrars of vital statistics have neglected to keep a record of the diseases engendered in this way. We are left to guess. It may be considered, however, as an unsuccessful matter. Nobody seems to have refrained from terror or caution; and the kissing epidemic seems to have raged with unmitigated violence all the year round. The kissing microbe has not yet yielded his ugly phiz to the microscope, and as far as we know the microbiologists are as reckless as others in exposing themselves to his ravages.

That life may originate *de novo* is neither so unphilosophic or problematic as may have been supposed.

Buckland has preserved the record of a race produced under the action of the galvanic battery, which subsisted, and even propagated, its kind.

If there is danger from carriers of contagion, whatever is in most general use should be avoided—and that is money—it is found in almost every place, handled by all sorts of people; by those afflicted with all kinds of disease; carried in filthy pockets; in the stockings of harlots; conveyed in every conceivable manner, and yet I have never known any of those microbists to refuse it; neither men in banks to be injured by it. I would propose, that to be consistent with their views, microbists reject it, and let those of us have it who are not afraid of these infinitesimal tramps. Earth has been brought from more than a hundred feet below the surface, covered with glass

and exposed to the rays of the sun, and in that condition produced vegetation. Indeed, when the trees of a particular character are destroyed in a forest, it is not unusual for a new growth to succeed wholly unlike the former.

If we consider the sun as the fountain of force, it can be no very great stretch of imagination to suppose that its active energy will incorporate itself with the various earths, and thus lead to the developing of new organisms and forms of life.

The same cause which has introduced into the universe must continue the benign influence, and creation thus be a matter of everyday occurrence.

This agrees with the account in the Book of Genesis: "Let the earth bring forth grass, the herb-yielding seed, and the fruit-tree yielding fruit after its kind, whose seed is in itself upon the earth." What has been in the order of the universe, always continues to be.

So with disease; it is as variable in form as life, and as likely to occur *de novo* when conditions promote it. A small-pox or fever will appear when the circumstances compel it, with no necessary specific poison other than what is incident in the case.

The nidus once established, it is liable to break forth in full energy.

If any question it, let them show that there was no first instance when the disease occurred; otherwise, however, plausible their reasoning may be, they beg the whole question at the beginning. Disorder is always incident to life, and once introduced will be liable to develop permanent conditions.

Such appears to be the rationale of the matter.

[Written for the MEDICAL BRIEF.]

Is Alcohol a Food?

BY J. W. LOCKHART, M. D.,
St. John, Wash.

It seems to me that the article by Dr. Dixon, on page 745, of the October number of THE MEDICAL BRIEF, under the caption of "The Action of Alcohol in Health and Disease," is worthy of more than a passing notice. In the first place his altogether gratuitous assumption that the "advocates of teetotalism" are the only ones who "believe that alcoholic beverages only make for evil" do not mark him as a man who wishes to publish a fair and unbiased opinion in regard to the matter. His statements seem not only to be biased but partake largely of the nature of special pleadings for interested parties.

For many years there has been no little controversy over the question of the physiological or pathological action of alcohol, and the discussion has been by no means one-sided, nor confined, on the one side, to the "advocates of teetotalism." The fact is, that in this country, at least, the advocates of total abstinence from alcohol as a beverage base their claims upon the statements and deductions of men who rank as high in the world of science as any that can be named, and whose opinions are not to be blown aside by a sneer at the "teetotalists."

As Dr. Dixon has presented a very one-sided view of the question, perhaps I may be pardoned for producing some important evidence on the other side, in order to refreshen memory and give the readers of THE MEDICAL BRIEF a chance to draw their own conclusions. Having conducted no experiments with alcohol, I will content myself by quoting from those who have, and who, on account of their confessed ability, have a right to be heard. First, then, I quote from Dr. G. H. Benton, Member of the American Society for the Study of Alcohol and Other Narcotics: "The many pathological degenerations of inebriety vary somewhat in proportion to the kind of liquors imbibed. If the drink is of the lesser concentrations of alcohol, such as beers, wines and ales, one will find more or less of the fatty degeneration in the early course, and less sclerosis; while the more concentrated forms, such as brandy, rum and gin, insure early sclerosis, and all forms produce acute and chronic gastric catarrh as one of the primary symptoms, together with cirrhosis or fatty degeneration of the liver, kidneys and heart, sclerosis and atheroma of the blood vessels, with shrinking and atrophy of both cells and nerve fibers and destruction of the dendrites." . . . "Alcohol, when introduced into the system, undergoes no digestive or other chemical change,

but is absorbed and circulates as alcohol. It coagulates the albumen with which it comes in contact. It absorbs water from the tissues. Its first impulse, therefore, on the circulatory system is contraction, but, secondarily, by its anesthetic effect, it paralyzes the vasomotor centers, vasodilation takes place, reducing the bodily temperature and requiring increased heart action." . . . "The direct action of alcohol is a protoplasmic poison. Its active affinity for water, albumin and oxygen, with which element it unites both in the blood and in the organized structures, especially its union with free oxygen in the blood, retards tissue metabolism. It increases the proportion of carbon dioxide and water. This lessens the bodily temperature and the sensibility of all nerve structures, cerebral, spinal and ganglionic."

Dr. Berkly, Johns Hopkins Hospital, Baltimore, is quoted as saying: "Alcohol in the system has a peculiar eroding action on the cells of the brain. At first this is confined to local centers, which increase, until finally a large part of the brain is involved."

The late Dr. Noah S. Davis, than whom no man was better entitled to speak on this subject, says: "Alcohol, when taken into the stomach in a pure and undiluted state, acts as a direct irritant poison, and is as speedily fatal as undiluted carbolic acid. When largely diluted, as beer, wine, whisky, brandy, rum and gin, it is rapidly absorbed without digestive or chemical change. It is carried in the blood current to every organized structure in the living body. . . . It nowhere undergoes assimilation or conversion into nutritive material for the growth or repair of the natural structures of the body. A careful analysis of all the facts obtainable not only shows that the presence of alcohol in the blood impairs every function, physical and mental, and every structure of the individual using it, but also extends the same impairing and degenerating influence to his or her offspring."

Dr. Max Kassowitz, University of Vienna, says: "Oxidation of alcohol in the blood neither involves any kind of physical force or energy, nor lessens the waste of nitrogenous elements, and consequently performs none of the function of a true food, either directly or indirectly, but favors the degeneration of almost every tissue. Alcohol is a protoplasmic poison and not a food, and under no circumstances can it act in a nutritive manner."

Dr. Winfield S. Hall, of Chicago, says: "Only such substances can be called food materials, or be employed as food, as, like albumen, fat and sugar exert non-poisonous influences in the amounts in which they reach the blood and must circulate in it in order to nourish." Of the sparing qualities of alcohol, he says: "I may say that these are very slight and their significance has been very much misunderstood by physiologists. They have generally thought that the consumption of tissue was decreased because of the oxidation of alcohol in a vicarious role, but it must be clear that the narcotic effect of alcohol, by decreasing activity, decreases oxidation of tissues. In this sense morphine and all other narcotics are foods."

Dr. Roeser, of Paris, said: "It is absorbed as alcohol, mixed with the blood, imbibed by the tissues and burned as alcohol, and the nervous excitation produced by the action of alcohol gives rise to the rapid combustion of the body reserves. Consequently, a substance which contributes nothing to the reserve tissue, which can be considered in no sense a source of physiological work, and gives rise to the development of a very small amount of heat—such a substance must be harmful, at least its utility is doubtful. It can not be regarded as a food."

Enough has been quoted to show that there are at least two sides to the question, and that argument is as logical on the one side as the other.

All agree that alcohol is not digested in the human stomach, while all true foods must undergo that process. All agree that alcohol is absorbed from the stomach and circulates in the body as alcohol. All agree that an uncertain per cent of alcohol is eliminated from the body through the kidneys, skin and lungs, while another some insist that an uncertain amount of it is oxidized in the body. All are, doubtless, to a certain extent, right in their opinions.

My own conclusions, drawn from no small amount of literature on the subject, is, briefly, this: Alcohol enters the sys-

tem as pure alcohol, unchanged by the digestive process. It has a well-known affinity for albumen and combines with it wherever the two substances come in contact, whether in the body or out of it. In the body these two substances unite, destroying, or at least greatly modifying the protoplasm from which all tissue cells are formed; and, also, part of the albumen of the blood, brain and nerves. This coagulated albumen or possibly an albuminate, acts only as a foreign substance perfectly worthless as a tissue builder or a heat producer. It is probably disintegrated and eliminated from the system in much the same way that other waste products are eliminated. This change in the brain and nerve substances, together with the foreign substances thus produced, is sufficient to account for all the symptoms of alcoholic intoxication, or poisoning, or alcoholism. All the functions of the brain and nervous system are benumbed and deadened in proportion to the amount of alcohol imbibed, while the symptoms are in ratio to the individual powers of self-control. This benumbing or narcotic effect of alcohol has given rise to the popular superstition that alcohol warms the body in cold, and cools it in warm weather. When the centers of locomotion are partially narcotized we see the staggering gait. When the centers of volition are partially narcotized we see the staggering intellect and the ineffectual efforts at coherency. This generally takes the form of more words and less sense.

Alcohol, by preventing normal cell metabolism, or the conversion of the protoplasm into normal tissue cells, compels the production of abnormal tissues, especially those depending on the carbohydrates for their elaboration. This theory satisfactorily accounts for the extraordinary accumulation of adipose tissue in constant drinkers, especially of beer, in which the alcohol, being more dilute and more constantly imbibed, produces a more constantly degenerating effect.

It is more than likely that all the alcohol not eliminated from the body through the kidneys, skin or lungs, is lost in its combination with the albumin and eliminated from the body as other waste products are eliminated.

If we are to regard alcohol as a true food simply because a small portion of it is, oxidized in the body, and regardless of the unconquerable, diseased-produced appetite, and the innumerable evils that follow its habitual use as a beverage, we must conclude, *a fortiori*, that all substances that can be oxidized in the body are true foods, regardless of their deleterious effect. This suggests the *reducio ad absurdum*. It is incumbent on the advocates of the theory to show that all substances capable of being oxidized in the body are true foods, or common honesty will compel them to admit that their theory is untenable.

I beg the editor's pardon for the length of this article, the interest and importance of the subject being my only excuse.

[Written for the MEDICAL BRIEF.]

Malarial Fever, Its History, Pathology, Symptoms and Diagnosis.

BY J. W. CRISMOND, M. D.,
Anderson, Ind.

Malaria, or paludism, is a subject that has occupied the medical mind since the days of Hippocrates, who, in his treatise on "Airs," attributes various diseases to a mixture of the blood with vitiated air. It has not been many years since this idea was as vigorously advocated by medical writers as in the time of Hippocrates; and, indeed, their teaching was not more rational.

I have often thought how misleading and unfortunate this idea was of attributing any definite entity to malaria, a contracted word, derived from the Italian *mala aria*, whose signification, from a medical point of view, means much or nothing. Bad air is made to cover a multitude of ailments, as well as a multiplicity of ignorance in the realm of pathology.

Vitiated air undoubtedly does lessen the resistive force of our bodies, and thereby render our system more susceptible to the encroachment of disease, but it is not the disease *per se*.

Is it not a fact that all diseases have their specific origin, and that the same cause will not change its identity by some

will-o'-the-wisp, and thereby produce a different disease, at the will of chance, but the same germ will always produce the same pathological condition.

Telluric intoxication, while faulty, is a better word than malaria, because it expresses more accurately the idea intended by the word malaria, namely, that certain diseases were produced by the action of air coming from soil, the energy of which is not expended upon vegetation. However, this term and the idea it conveys is rejected by a large number of medical men of the more advanced school of science.

Miasm, one of the many appellations for autumnal and vernal fevers, seems to be so thoroughly ingrafted upon the medical mind that it is almost impossible to disabuse the mind of the fact that "malarial fever" is not caused by "floating and impalpable morbific effluvia, the product of the decay or putrefaction of animal and vegetable substances." However unreasonable it may appear to some conservative students of the causation of disease, and however imperfectly established may appear the hypothesis that malarial diseases are caused solely by invasion of the body by a specific bacteria, this is the view of almost all modern writers on the subject.

The hardest thing for one to do is to cast off and get away from one's early training, to completely divest one's self of preconceived and time-honored opinions, which has been so zealously advocated, and so universally accepted as settled facts.

The first substantial proof of the bacterial origin of malarial disease is that produced by Professor Tommasi-Crudeli, of Rome (1870), and Professor Klebs, of Prague, who discovered a microscopic fungus in the lower strata of the air of a malarial region in Italy, and in the soil and stagnant waters, which they name bacillus malariæ. They found that this micro-organism, when cultivated in various media, and properly diluted, and injected under the skin of dogs, produced in them typical intermittent fever.

Before the ever-advancing tide of discovery old opinions and settled convictions give way to new ideas and uncontrovertible facts in their onward march.

We find this explanation of the causation of malarial fever supplanted, to a great extent, by Laveran, who first advanced the idea that there is always a peculiar organism (hematogeon) not found in any other disease.

This parasite has been carefully studied by Professor Osler and Professor Councilman, of Johns Hopkins University, and Professor Dock, of the University of Michigan. The clinical aspect of the different forms and phases of malarial fever are dependent upon and associated with the various forms and stages of the development of the plasmodium malaria.

Since the publication of Laveran's discovery, his observations have been confirmed and enlarged upon by many observers in all parts of the world, and while but little is yet known of the life of the organism, outside of the human body, its causative relation to malarial fever has been conclusively demonstrated.

Golgi (1885-86) proved the relation existing between the different stages of the malarial paroxysm and the cycle of the development of the parasite.

He demonstrated that there were two varieties of the parasites, as belonging each to quartan and tertian fever.

In 1889, Marchiafava and Celli recognized particular forms associated with estivo-autumnal fever.

Sternberg, in 1880, repeated the experiments of Kleb and Tommasi-Crudeli, in the vicinity of New Orleans. His labors failed to confirm that of Tommasi-Crudeli and Klebs.

Sternberg's conclusions are as follows:

"Later researches have also failed to confirm the supposed discovery of Klebs and Tommasi-Crudeli, and it is now generally admitted that there is no satisfactory evidence in favor of this view that micro-organisms of this class are concerned in the etiology of malarial fevers."

On the other hand, we have now very extended observations, which indicate that the blood parasite discovered by Laveran (1881) in the blood of patients suffering from various forms of malarial fevers, bears an etiological relation to fevers of this class.

This hematozoon belongs to quite a different class of micro-organisms. It is

more frequently spoken of at present as the plasmodium malariæ.

"Personal observation," says Professor Von Jaksch, "no less than the study of what has been written on the subject, have satisfied the author that the blood in malaria contains specific organisms, as Laveran first pointed out, and that these specific organisms are the determining cause of the disease."

Hehir, after careful investigations of the blood of malarial patients, in India, has concluded that there were constantly present in such blood eight different forms, including the phagocytes, which may be observed to take an active part in the morbid process.

Mode of Infection.—If the contention as to the etiology of malarial disease is well founded, there can be but one answer as to infection, and that is by inoculation.

It has been conclusively proven by inoculation experiments that infection may take place through the skin, and, in addition, that the different varieties of malarial parasites have each a more or less definite period of incubation, when infection is brought about in this manner. The insects that do the inoculation are most likely to be the mosquito.

The plausibility of the inoculation theory is very much enhanced when comparisons are made between malaria and other parasitic blood infections of man and the lower animals.

The tsetse-fly disease of Africa is due to a flagellata infusorium. The fly, by feeding upon an animal already infected, and then biting a healthy animal, will act as a carrier of the parasite from the infected to the uninfected.

The transmission of the Texas fever, which is due to a protozoon, is another good illustration.

Also, the *filaria sanguinis hominis* is carried from the sick to the well by the mosquito. The very various circumstances associated with the conditions under which malaria prevails that may be reconciled with the theory that the mosquito is an important factor in the transmission of the parasite.

Consider, for instance, the relative immunity possessed by those sleeping in the upper stories of a dwelling in malarious regions is susceptible of explanation by the limited extent to which the flight of mosquitoes is elevated above ground.

Further, it is well known that mosquitoes are unlikely to leave the region in which they were generated, and that as soon as a strong wind prevails they seek such shelter that the wind carries them for a limited distance only.

The name of the mosquito which is successful in inoculating persons is *culex penicillasis*, or the so-called *culex malaria*.

Symptomatology—Period of Incubation.—A certain time elapses after inoculation takes place, and this period of incubation varies from a few hours to many days, before there is any manifestation of disturbance in the functions.

No definite period has, as yet, been fixed at which the malarial explosion takes place, the variations being due to the intensity of the poison, susceptibility, and the resistive force of the individual. The average is stated to be about fourteen days.

In a large proportion of cases there are symptoms indicating the plasmodium malariæ are developing in the blood in two to four days after infection.

This is termed the prodromal stage of the disease.

The affected one experiences a feeling of lassitude and weariness, there is backache and general muscular soreness, an irresistible desire to yawn and stretch, and especially is this so in the early morning and on cold, damp days. He complains of headache, his tongue is coated, his stomach is squeamish, and, as evening comes on, his skin becomes warm and dry, his sleep is more or less disturbed by dreams, and, as morning approaches, will usher in a profuse sweat.

In another class of cases the prodromes consist merely in a coated tongue, icteric, sclerotic, and a general yellowish hue of the skin, languor, loss of appetite, and constipation; the urine is loaded with bile-pigment, and deposits an abundance of urates.

The patient may gradually drift into fever, or the disease may begin abruptly in the midst of apparently full health. Intermittent fever occurs in paroxysms, separated by intermission or non-febrile periods.

The paroxysms may recur daily, constituting the quotidian form, or alternate days, the tertian form, since it recurs on the third day. There is also a quartan form; exceptionally there may be a double quotidian, with one strong and one mild attack each day; a double tertian, with a daily onset, that of every second day being relatively weak; a double quartan, having two attacks in every three days.

Febrile paroxysms usually recur at a definite hour each day or alternate day. Recurrence of successive paroxysms, at an earlier hour for each attack, is termed anticipating, and indicates an increasing malarial influence. When the paroxysms come at a later period, with successive attacks, it is termed postponing or retarding, and indicates a subsidence of the malarial influence.

Clinical Types.—Malarial fevers are divided into two main groups: First, the fevers due to infection with ordinary tertian and quartan parasites of Golgi. Second, the fever due to infection with the estivo-autumnal or crescent-forming parasite.

Under these two main groups, which may also be termed, respectively, the regularly intermittent fevers and the more irregular, often continued or subcontinued fevers, may be differentiated three types of fever:

1. Tertian fevers;. single and double infections.

2. Quartan fever; single, double and triple.

Both types comprising the first group of fevers.

3. The second group of fevers; the estivo-autumnal.

Tertian fever is of common occurrence in almost all malarial districts. The quartan type, while the common fever in a few malarial regions, such as Sicily, is, in most regions, where other varieties of infection are common, of rare occurrence.

Tertian Intermittent Fever.—In this form of fever the infection is with a single group of tertian parasites, each individual member of which is in approximately the same stage of development; so that segmentation of all, with which the paroxysm is associated, takes place at about the same time.

The time necessary for the completion of the cycle of development of the tertian parasite is about forty-eight hours, sometimes a little more, sometimes a little less, the latter more commonly than the former.

The paroxysm may be divided into three stages: the chill, the fever, and the sweating stage.

Unpleasant feelings, ill-defined sensations of discomfort, usually precede the chill, and in an individual who has ever experienced a malarial outbreak, are peculiarly significant of what is to follow. Even at this time some elevation of the temperature may be noted, while the surface of the body is cold, and the skin, owing to the erection of the hair-follicles, presents the condition of goose-flesh; the internal temperature, as determined in the rectum, is high, often 105° or 106° F. The skin is pale, often bluish in color, and the visual disturbances, headache, dizziness, nausea, and vomiting, are common. The pulse is tense, small, and accelerated. The duration of the chill is variable, usually from ten minutes to half an hour, or an hour, or even longer.

The febrile stage gradually supervenes upon the stage of chill, until by repeated flushes of heat, the stage of chill is completely superseded, and the patient throws off the additional bed-clothing which, a short time before, was so gratefully accepted.

The skin becomes hot, dry, and reddened, and a sense of burning heat is complained of; the conjunctivæ are suffused, the pulse rapid, full and bounding; intense headache, dizziness, and, occasionally, delirium occurs, or the patient may be drowsy and somnolent.

Epistaxis, diarrhea and vomiting are among the less frequently occurring symptoms.

Herpes of the lips and nose, while erythema and urticaria are sometimes seen.

In most cases the splenic tumor may be readily detected.

The duration of this stage is usually four or five hours, and the temperature now attains its greatest elevation.

With the initiation of the sweating stage the patient experiences great relief. At first perspiration is noticed to occur about the forehead and upon the face, but shortly spreads over the whole body, usually becoming most profuse.

The temperature rapidly falls, so that in two or three hours it has reached a subnormal point, where it remains for some time. The patient now sinks into a refreshing sleep.

The intermission continues until the young parasites derived from the segmentation that has caused the first paroxysm, in their turn pass through their cycle of development until the stage of segmentation is attained, and with it occurs the second paroxysm.

The time thus occupied is forty-eight hours, longer or shorter, resulting in anticipation, or retardation of the paroxysm.

During the intermission, the temperature remains subnormal for some hours, and the patient experiences great relief.

Quotidian intermittent fever is the result of two groups of tertian parasites, which is found in the blood of these patients in different stages of development, which reaches maturity, or the stage of segmentation, upon alternate days. This gives birth to the quotidian or daily paroxysms peculiar to single tertian infections.

Because one group may be larger than its congener at the time of inoculation, it is not uncommon for the paroxysms to be tertian in type until the smaller group has attained sufficient size to cause a paroxysm.

As one group may be greater in number, it is not uncommon for the paroxysms produced by this group to be of greater severity than those produced by the lesser group.

The usual order of segmentation is for it to occur at a different hour from each other, and this accounts for the onset of the paroxysms at different hours.

There is no difference in the paroxysm in the quartan fever from that of the tertian fever.

About seventy-two hours is required for the completion of the cycle of development. The coincident paroxysms and segmentation of the parasites occurs every fourth day, and an intermission of two days existing between.

The exacerbation marked by three stages of rigor, fever, and diaphoresis, of an average duration of about ten to twelve hours.

The characteristic of this type of fever is to occur with great regularity, and to show very little tendency toward retardation.

Double-quartan fever occurs when two groups of quartan parasites exist in the blood at the same time, and attain the stage of segmentation upon successive days.

The exacerbations which take place upon two days in succession, is followed by a day of intermission or rest.

We also have triple-quartan infection, and this is due to the existence in the blood of these groups of quartan parasites, in different stages of development, and segmenting upon successive days.

Here we have daily exacerbations, coupled with all of the phenomena of quotidian intermittent fever.

The Spleen.—The spleen is always involved in malaria. It is enlarged, but its hypertrophy varies in degree. Its firmness or solidity is diminished, often so much so that an attempt to dislodge it results in rupture of its tense capsule, which gives vent to its dissolving pulp.

The parenchyma is frequently the seat of a melanosis, varying in intensity from a dark brown to almost deep black.

The incised surface presents a dark gray-brown or slaty color, and the unpigmented. Malpighian corpuscles stand out prominently. The capsule is very thin and easily lacerated. The venous sinuses are dilated, as is revealed by the microscope.

In the parenchyma is crowded a prodigous number of red blood-corpuscles which, to a great extent, is found to contain parasites in all stages of development, and sometimes free parasites are to be found.

One of the marked characteristics is the presence of a large number of phagocytes, particularly the macrophages. White leucocytic phagocytes occur, especially the large-cell variety, which exist in very large numbers.

The peculiarity of the protoplasm cells is seen to contain pigment-granules, in

clumps or rods, as well as parasites free or included within their corpuscular host. The parasites seem to complete their cycle of existence while within the macrophages.

The Liver.—The liver is more or less enlarged and congested, and contains a large amount of dark slate-colored pigment, often almost black.

The capillaries, hepatic artery, portal vein, and hepatic vein, when viewed microscopically, are found to contain myriads of parasites.

The branches of the portal vein contain the very largest macrophages, which have originated in the spleen, and which, on account of their large size, obstruct the caliber of the vessels.

The Kidneys.—In the glomeruli, the cortex, and along the course of the vessels in the pyramids, pigmentation may be observed, especially in the glomeruli, and pigment being contained within large leucocytes, which may produce a narrowing of the caliber of the vessels.

Degeneration and desquamation of the epithelium of the corpuscles of Bowman constitute one of the most serious lesions. In hemoglobinuric, or black-water, fever, the change in the kidneys are most marked. The kidneys usually increase in size, of somewhat lessened solidity, and of mixed color, being often pale and anemic in appearance, and at times they are a darkened color.

There are observed scattered brownish spots, due to pigment deposits, which crowd the epithelium and lumina of the uriniferous tubules.

Upon microscopical examination, the renal epithelium is found to contain pigment, and pigment-rodlets, or fine yellow granular, or dark, amorphous masses, are observed to fill the lumina of the uriniferous tubules.

The Brain.—There is usually a distinct localization of the infected blood-corpuscles which appear to take in the cerebral capillaries, and then melanotic discoloration of the cortex may occur, with deep injection of the blood vessels, and, not infrequently, numerous punctiform hemorrhages.

Parasites in all stages of development, although one stage usually predominates, crowd the cerebral capillaries until, in places, complete obstruction or thrombosis of their lumina takes place.

These parasites, although commonly seen to be within red-blood corpuscles, may be free, or contained, together with pigment or blood corpuscles, within phagocytes.

The Bone Marrow.—The bone-marrow is of brown-red color, sometimes almost black. It is soft, almost diffluent.

The vessels are found to contain developing, as well as sporulating, parasites, and crescents are usually present in abundance. About the periphery of the lumina of the vessels macrophages containing pigment may be found in considerable numbers.

Diagnosis.—The diagnosis of malarial fevers depends upon the result of the examination of the blood, and the more doubtful the case the more it resembles some other affliction, the more necessary is the resort to this means of attaining a positive conclusion.

To a less degree, the diagnosis is established by the results of the therapeutic test: The administration of quinine and the clinical manifestations.

Celli and Guarnieri obtained excellent stained specimens of the parasite in fresh condition, by mixing the blood with ascitic fluid deeply tinged with methylene-blue.

It may be prepared thus: Methylene-blue is dissolved in normal saline solution until the fluid is somewhat deeply colored. The solution is then filtered, sterilized, and set apart in small quantities in thoroughly-sterilized test-tubes. The point of the finger is then carefully cleaned, a drop of the staining fluid applied to it, and through this the finger is pricked with a needle.

The flowing blood, mixed with the staining fluid, is brought in contact with a cover-glass, and this is placed preparation-side downwards upon a slide and examined.

The preparation must be spread in a very thin layer, and it is, therefore, necessary to guard against evaporation.

This may be done by sealing the edge of the cover-glass with paraffin wax.

It may be examined first with a fairly-wide aperture of the diaphragm, and afterwards with an open condenser, and a good oil-immersion lens.

[Written for the MEDICAL BRIEF.]

Water the Cure-All—The Modern Medical Treatment Which Replaces Drugs.

BY J. WATERLOO DINSDALE, M. D.,
Prescott, Arizona.

A great number of every-day little illnesses, and for that matter, many important ones, have their remedy or antidote always at hand. And it is a pity that the efficacy of that remedy is not more generally recognized, seeing that it is within the reach of everyone.

This wonderful agent, which almost might be called a panacea, is simply water, used intelligently.

The chief great advantage that water has over drugs is that it acts directly on the body, whereas the body usually acts upon the drug, attempting to rid itself of it.

Its great action is upon the superficial or outside little blood vessels, which either by expanding and so becoming flooded with blood, or else by contracting and so driving the blood into organs under the skin in the region to which the water is applied, set right the temporarily impaired mechanism.

Palpitation of the heart is a very unpleasant and sometimes terrifying affection. Very frequently it is not associated with any important, serious disease of the heart, but, nevertheless, it may cause grave discomfort. Which is the better, then: To send off post-haste for a physician to administer drugs, or to lie down quietly and apply cold water bandages over the heart? In a few moments this simple remedy will slow the heart's action to normal.

In the same way the skin over the liver is associated with that organ. Cold water applications over the skin of this part cause the vessels to contract, whereas hot water bandages dilate the vessels of the organ. Therefore the blood can be forced on if the liver is congested, or if blood is needed in that organ it can be brought there by these simple means.

The same thing applies to congestion of the kidneys. A hot bath will bring the blood racing to the spot, and the kidneys will be thoroughly flushed by the only real healing agent, the blood.

When a man faints, and is lying quite helpless, the old-fashioned person who wishes to dash a little cold water in the patient's face is too often nowadays shouldered aside by the up-to-date amateur physician, who knows all about the heart-stimulating properties of brandy, whisky, etc. There is no doubt that in certain cases fire water is a very useful heart stimulant, but for a simple faint they are always unnecessary.

In an acute fit of indigestion such as this in an ordinarily healthy stomach, are drugs, pepsin, and other digestive ferments necessary? No, assuredly not. A hot application over the stomach, followed by a cold application and abdominal massage, will afford immediate relief.

Almost every organ in the body can be reached by water applications, hot or cold, as the case may be, and the only knowledge necessary for their intelligent use is whether the blood supply of the organ needs to be stimulated or retarded.

In acute sore throat, tonsillitis, or any acute inflammation of the mucous membrane of the throat, wet packs made by folding a towel into four thicknesses and wringing out in very hot water, and then covering with a woollen wrapping, are very effective in relieving pain and reducing inflammation. A head-pack is useful for headaches of nervous origin, or caused by cerebral anemia, when there is an insufficient supply of blood to the head. In these cases wrap the head in a towel wrung out in ordinary cool water, and cover with a dry, thick woollen cloth. This may remain on for hours.

If, on the other hand, the headache is caused by congestion of the blood vessels of the head, the towel should be dipped in as cold water as possible, and should not be covered by any wrapper. Evaporation (and so cooling) should be encouraged, and the towel should be renewed as soon as it becomes warm. A wet pack is often very useful for the pain of sciatica, or for lameness after over-exertion and sprains.

Spinal tenderness and inflammatory rheumatism:

1. The amount of vitality destroyed by the fear and dread of passing through an operation, with the operation combined, often puts cases beyond hope, that could easily have been cured if the right treatment had been given.

2. To cut into the deep tissues of the body makes a severe wound in addition to the present existing trouble. The amount of vitality required to heal such a wound draws heavily on the vital force of the patient already over-taxed.

3. The anesthetic usually administered under such circumstances still further reduces the vital force of the patient.

4. The pain and sickness caused by the operation has a similar effect. Any one of these detrimental influences are often sufficient to cause the death of a very weak patient. *It is an appalling fact that actual murder is often committed by performing needless surgical operations and giving poisons as medicine.* Every one, whether layman or physician, who holds in his hands the life of a human being, should seriously consider what an awful thing it is to give a drug. The tendency is to kill, while trying to cure. To say the very least, it is an exceedingly contradictory and an unreasonable act.

Questions Presented by the State Medical Examining Board of Washington, at Seattle, July 2, 3 and 4, 1907.

SURGERY.

1. Give two methods of treating hydrocele of the testicles surgically, and briefly state the details of one.

2. Give the symptoms and treatment of fracture of the middle third of the femur.

3. Make a diagnosis of chronic suppuration of the antrum of Highmore. What is the treatment?

4. Give the treatment of large varicose ulcers of the leg.

5. What are the cardinal symptoms of fracture of the base of the skull?

6. Give in detail the treatment of a gunshot wound of the chest traversing the pleural cavity, with hemothorax compressing the lung.

7. Give, in detail, your treatment of hemorroids. Give the method of operation, and your reason for selecting the same.

8. Give your management of a man sixty years old, with an enlarged prostate, unable to urinate without the use of the catheter, otherwise physically sound. If you would operate, state why, and give the details of the operation.

9. Give the treatment of the various stages of a tubercular knee.

10. Upon the presence of what symptoms in one suffering from gall-stone disease would you base the necessity of an operation? Give a brief synopsis of such an operation.

PREVENTIVE MEDICINE AND MEDICAL JURISPRUDENCE.

1. What precautions would you employ to prevent the spread of (*a*) typhoid fever, (*b*) tuberculosis, (*c*) tetanus, and (*d*) malaria?

2. Name five disinfectants in the order of their potency and usefulness, strength of each used, and their composition.

3. Give two satisfactory methods of disposing of sewage.

4. Mention the parasitic diseases that may be communicated to man by food.

5. Give details for policing a camp, including sterilization of water and disinfection of excreta.

6. Differentiate between suffocation, strangulation, hanging and drowning.

7. Give data upon which an opinion is formed as to the length of time which has elapsed since death.

8. What precautions should be observed when taking dying declarations? When do dying declarations become admissible as evidence?

9. How would you prove by a *post-mortem* that a woman had recently been pregnant?

10. How would you determine a dead babe was not full-term?

OBSTETRICS AND GYNECOLOGY.

1. Define pelvimetry. What measurements obtained thereby should determine interference?

2. Give the objective signs of pregnancy in the order of their appearance, and state their relative value.

3. Give the differential diagnosis between pregnancy and pelvic tumors.

4. Give a brief description of the mechanism of normal labor.

5. What are the varieties and importance of perineal lacerations?

6. With what are sarcoma and carcinoma of the body of the uterus most likely to be confused, and how is the differential diagnosis made?

7. Name three varieties of extra-uterine gestation. Which is the most common and how diagnosed?

8. Give the diagnosis and treatment of ovaritis, both acute and chronic.

9. Define the term "uterine polypus," and state the varieties usually recognized in gynecology.

10. Describe the marks that exist upon the head as discovered by digital examination in the various occipital presentations, and their relative positions that would lead you to make a diagnosis of the presentation.

HOMEOPATHIC MATERIA MEDICA.

1. Give key-note symptoms of hyoscyamus, lycopodium, ignatia, sulphur and natrum mur.

2. Differentiate the heart symptoms of digitalis, kalmia, cactus grand. and spigelia.

3. Describe an arsenical album patient.

4. What are the indications for the following remedies in hemorrhage: (*a*) china, (*b*) ipecac, (*c*) trilliub, (*d*) erigeron.

5. What remedies are indicated in diphtheria? Give indications for each one mentioned.

6. Differentiate phytolacca and kali bich. in angina faucium.

7. Differentiate between aconite, belladonna, arsenicum alb., in fevers.

8. Give four remedies of use in diarrhea, with their characteristic symptoms.

9. What conditions indicate hypericum, arnica, rhus tox., in injuries?

10. Describe in full a natrum mur. patient.

ANATOMY AND PHYSIOLOGY.

1. Describe the method of locating the fissures of Rolando, and the parieto-occipital by extracranial measurement.

2. Give a brief description of the hip-joint, and name the ligaments and muscles that are concerned in its motion.

3. Give all the muscular attachments to the humerus, indicating the anatomic location of each.

4. What structures form (*a*) Hunter's canal, (*b*) popliteal space? Give the contents of each.

5. What are the branches of the first, second, third and fourth lumbar nerves.

6. Name the muscles of inspiration and expiration. Give the attachments of each.

7. Answer the following points in reference to the occipital bone: (*a*) angles, how many and what are they? (*b*) articulations; (*c*) lines, name muscular attachment of each; (*d*) processes, name the muscular attachments of each; (*e*) protuberances; (*f*) sinuses, how many and how formed? (*g*) fossæ, what lobes of the brain lie in each; (*h*) foramen, transmitting what?

8. Name the branches of the following arteries : (*a*) axillary, (*b*) radial, (*c*) internal iliac.

9. What are the sources of calorification in warm-blooded animals?

10. Name the secretions and excretions of the body, indicating which are alkaline, and which are acid in reaction.

11. What are the origin, uses and most important purposes of lymph and chyle?

12. Briefly indicate the action of the salivary, gastric and intestinal secretions on meats, starches and sugars.

13. Compare the general properties and composition of human and cow's milk.

14. Briefly describe the mechanism of the special senses of touch, olfaction, gustation, vision, audition.

ECLECTIC MATERIA MEDICA.

1. What are specific medicines?

2. Give your reasons for being an Eclectic. Wherein does it differ from the regular?

3. Name ten agents that influence the nervous tissues.

4. Define tonics and name six.

5. What are the indications for (*a*) gentian, (*b*) lupulin, (*c*) podophyllin, (*d*) zanthoxylin.

6. What remedy would you employ in rheumatism of the joints?

7. Name six diuretics and give the indications for the use of each.

8. Give the treatment for a case of pneumonia, and give your reason for the agents used.

9. What is a stimulant? Can an agent be a stimulant in small doses and a narcotic in large ones? Is alcohol a stimulant?

10. When would you use (*a*) galium aparine? (*b*) epigea repens? (*c*) leptandra virginica? (*d*) euonymous atropurpuretus? (*e*) apocynum and rosæmifolium? (*f*) hydrastis canadensis?

HISTOLOGY, PATHOLOGY AND BACTERIOLOGY.

1. Give the histologic structure of the mammary gland.

2. Describe the histology of the solitary glands of the intestines.

3. Name the various kinds of epithelial cells, and the location of each.

4. Give the histology of bone.

5. Give the pathologic appearance, gross and microscopic, of cancer of the breast.

6. Name the different tissues subject to tubercular infection.

7. In case of an infection of the finger, name the pathologic steps of secondary general infection.

8. What are the pathogenic germs? Give three examples.

9. What bacteria normally exist in the intestines?

10. Describe the appearance of tubercule bacilli and gonococci.

NERVOUS DISEASES AND DISEASES OF THE EYE AND EAR.

1. Give the diagnosis, prognosis and management of locomotor ataxia.

2. Locate the lesion of aphasia.

3. Differentiate grand-mal, hystero-epilepsy and Jacksonian or focal epilepsy.

4. Differentiate between paralysis agitans and chorea.

5. Give the etiology, symptoms, diagnosis and treatment of epidemic cerebro-spinal meningitis.

6. Give the management of acute ulceration of the cornea.

7. Give the etiology, symptoms and diagnosis of plastic iritis.

8. What is dacryo-cystitis? Give the diagnosis and treatment.

9. Give the method of extracting foreign bodies from the auditory canal.

10. What is the indication for paracentesis of the tympanum? Give the technique.

CHEMISTRY AND TOXICOLOGY.

1. Describe in detail a method of making hydrogen. Give the formula and equation.

2. Distinguish by chemical tests starch from sugar.

3. How do each of the following affect litmus paper: (*a*) blood, (*b*) urine, (*c*) saliva, (*d*) H_2SO_4; (*e*) NH_4OH?

4. From what natural sources are derived (*a*) phosphorus, (*b*) chlorine, (*c*) iodine?

5. Why are eggs administered in corrosive sublimate poisoning? What new compound is formed?

6. Discuss ptomaine poisoning.

7. Describe the difference between chemical and physiologic incompatibility. Illustrate.

8. Give chemical name for (*a*) Rochelle salts, (*b*) Glauber's salts, (*c*) oil of vitriol, (*d*) blue vitriol, (*e*) sal-soda, (*f*) copperas.

9. Differentiate between opium poisoning and alcoholic narcosis.

10. What is the chemical composition of gall-stones?

MATERIA MEDICA AND THERAPEUTICS.

1. Name (*a*) three drugs that dilate the pupil, (*b*) two that contract it.

2. How is calomel abstracted from the gastro-intestinal tract? Give the method of administration to produce catharsis and systemic effect, and precautions that should be taken.

3. How do the following drugs act as diuretics: (*a*) digitalis, (*b*) caffein, (*c*) calomel, (*d*) diuretin, (*e*) acetate of potash, (*f*) spiritus etheris nitrosi?

4. Name four drugs that should be administered during pregnancy.

5. Name the methods of producing local anesthesia and explain the physiologic action of the same.

6. Write a prescription containing three ingredients each, for fever, cough, and diarrhea, and the indications for each drug.

7. Name the therapeutic use of water and methods of using the same.

8. Describe the physiologic effects of phenacetin.

9. Give the doses for various purposes of (*a*) plumbi acetas, (*b*) cupri sulphas, (*c*) ferri sulphas, (*d*) argenti nitras, and (*e*) bismuthi subnitras.

10. Give four diaphoretics and give dose of each.

PRACTICE OF MEDICINE AND DISEASES OF CHILDREN.

1. Give the cause and symptoms of general arterial sclerosis.

2. What is myocarditis? Give the etiology, symptoms and prognosis.

3. (*a*) What is emphysema of the lungs? Of what is it usually a sequel? (*b*) What is bronchiectasis? Of what is it usually a sequel?

4. What is cirrhosis of the liver? Give the symptoms.

5. Give the diagnostic symptoms of incipient tuberculosis of the lungs.

6. Differentiate between typhoid and malarial fever.

7. Give the subjective and predisposing symptoms of cancer of the stomach.

8. Describe the pulses in the following conditions: (*a*) apoplexy, (*b*) exophthalmic goitre, (*c*) typhoid fever, second week and fourth week, (*d*) pneumonia in various stages, (*e*) double aortic murmur, (*f*) mitral murmur, and (*g*) various stages of consumption.

9. Give the symptoms, prognosis, and treatment of infantile scurvy.

10. Name the exanthemata. Give the symptoms and treatment of one of them.

11. Describe a rachitic child, and give the treatment for the disease.

12. Give the complications of scarlet fever, diphtheria and measles.

13. Given a child fed on modified milk, constipation and curds in the stools, what changes would you make in the preparation, and why?

14. How many forms of icterus are seen in the newly-born child and upon what do they depend?

15. Name two kinds of croup, and give the appropriate treatment of each.

Report of Board of Medical Examiners of Maryland—Questions at the June (1907) Examinations.

ANATOMY.

1. Describe the frontal bone, including its articulations and sinus.

2. Name the branches, and give the relations of the external carotid artery.

3. Give relations of liver. Name lobes of liver.

4. Name structures severed by amputation through middle of leg.

5. Name and locate ventricles of brain.

6. Name the form of inguinal hernia, and give the difference between them.

SURGERY.

1. Give the cause and treatment of external hemorrhoids—(*a*) palliative, (*b*) one operative method.

2. What are the indications for operative treatment in any form of hernia?

3. What are the signs and symptoms, and what is the surgical treatment of a purulent effusion into the knee joint?

4. Give in detail the treatment of a recent compound fracture of the middle third of the tibia.

5. Give the differential diagnosis between acute inflammation of the middle ear and mastoiditis.

6. Give the evidences and treatment of a wound penetrating the bladder.

PATHOLOGY.

1. Name the organisms most frequently associated with each type of pleurisy, and give in detail the method of staining of each organism.

2. Define thrombosis, embolism and infarction, and name the organs in which infarction most frequently occurs.

3. Define sarcoma and carcinoma. Give the various types, and the chief avenues of extension of each, and name the sarcomata in the order of their malignancy.

4. Define the term general anasarca, and give a gross pathological description of the lesion which usually gives rise to it.

5. Name the varieties of meningitis from a bacteriolgical standpoint, and describe the elements you would expect to find in the fluid from a case of the epidemic variety.

6. Give the gross pathology of amebic dysentery. Describe the organism giving

rise to it, and name the pathological condition of the liver often associated with it.

OBSTETRICS AND GYNECOLOGY.

1. Give treatment for case of placenta previa.

2. How would you manage a twin labor, one foot of each child presenting?

3. Diagnosis and treatment of ovarian cyst.

4. How would you treat a case of gonorrheal conjunctivitis in an infant?

5. What treatment would you adopt in a case of umbilical hernia in an infant?

6. How would you manage a posterior shoulder presentation?

PRACTICE.

1. Define (*a*) myxedema, (*b*) chlorosis, (*c*) tinea circinata, (*d*) enteritis, (*e*) tabes dorsalis.

2. Differential diagnosis between (*a*) hysteria and epilepsy, (*b*) cancer and ulcer of the stomach.

3. Give signs of arteriosclerosis.

4. Give symptoms of Graves' or Basedow's disease.

5. Give differential diagnosis between varicella and varioloid.

6. Give treatment of (*a*) uremia, (*b*) empyema, (*c*) pertussis.

CHEMISTRY.

1. Define the terms dialysis, osmosis, crystalloid and colloid.

2. Give the chemical name for cooking (baking) soda and washing soda, respectively, and state the general properties of each.

3. What, chemically, is glycerine? Give its chemical composition (formula). State its usual source, and give its general properties.

4. Give in detail two reliable dissimilar tests for the detection of sugar in the urine.

5. Give the chemical composition (formula) of urea; state the usual amount excreted in twenty-four hours, and give in detail a reliable method for its quantitative estimation.

6. Give in detail a reliable test for the estimation of the total acidity of a specimen of gastric contents.

MATERIA MEDICA.

1. Name the mineral acids, and give the dose of each.

2. What are the preparations of the phosphates, and their doses?

3. What are the official preparations and doses of iodine, and the iodides?

4. What are the official preparations of ergot, and their doses?

5. Give the official preparations and doses of nux vomica and its alkaloids.

6. What are the principal direct and indirect emmenagogues?

THERAPEUTICS.

1. What are the physiological effects and therapeutic uses of hyoscyamus and its alkaloids?

2. Give the physiological action of nitroglycerin, indications and contraindications for its use.

3. What do we understand by the term alterative, and name the principal drugs of this kind.

4. Describe in detail the treatment for tapeworm.

5. How do disinfectants act? Name the principal ones.

6. Define local and general anesthesia. Name means and method of producing, and sources of danger.

PHYSIOLOGY.

1. What portion of the gastro-intestinal tract accomplishes the greatest amount of absorption? (*b*) State what class of substances are absorbed in the stomach, small and large intestines.

2. What are the sources of oxygen and carbonic-acid gas in the system? (*b*) What is the effect of each upon the blood? (*c*) What is the average quantity of oxygen in venous and arterial blood? (*d*) What are the symptoms of insufficient oxygen in the blood?

3. Explain the effect of muscular activity upon amount and character of metabolism of body, and the influence upon this metabolism of variation in the composition of the diet.

4. What are ptyalin, pepsin and pancreatin, and in about what proportion are pepsin and pancreatin found?

5. Describe the condition known as apnea.

6. What becomes of the biliary salts which are constantly poured into the upper part of the intestinal canal? Give test for biliary salts.

Book Notices.

GYNECOLOGY AND ABDOMINAL SURGERY. Edited by Howard A. Kelly, M. D., F. R. C. S. (Hon. Edin.), Professor of Gynecologic Surgery at the Johns Hopkins University; Gynecologist to the Johns Hopkins Hospital, Baltimore. And Charles P. Noble, M. D., Clinical Professor of Gynecology at the Woman's Medical College, Philadelphia; Surgeon-in-Chief, Kensington Hospital for Women, Philadelphia. Illustrated by Hermann Becker, Max Brödel, and others. In two large octavo volumes. Vol. I. has eight hundred and fifty-one pages, with four hundred and five original illustrations. Philadelphia and London: W. B. Saunders Co. Price, per volume, cloth, $8.00; one-half morocco, $9.50.

Gynecology, which is so closely associated, in many ways, with abdominal surgery, is an important and deep subject to consider. Of course, when such practical men as Dr. Howard A. Kelly and Dr. Charles P. Noble undertake the task of producing a work on this subject, we know that the latest and best that could be said will be found on its pages, and by eliminating the text-book matter on the subject, they have been able to confine this work to two large volumes of original matter, so they should be read by all who take an interest in gynecology and abdominal surgery. We believe that this is the first time that these studies have been so closely associated. From the standpoint of surgical gynecology it is important, as other works have been written on medical (or non-surgical) gynecology. The authors say, concerning the relative advantages of the abdominal and the vaginal route, for the performance of various operations there are still divided differences of opinion. Here we have presented the claims of the two schools, from the affirmative standpoint, by selecting tried advocates to present each side; therefore the reader may make his own deductions, aided by the master minds in the editorial work of the authors. It is readily seen by the examinations of the graduates of the different schools before the State boards, that gynecological work has the largest percentages. This shows the great and increasing interest taken by students along this line of study.

THE NEGRO, A Menace to American Civilization. By R. W. Shufeldt, M. D., Major Medical Department, United States Army (Retired). Member the National Geographic Society; Cor. Member Societa Italiana d' Antropologia, Ethnologia, e Pricolgia Comparata, Florence, Italy; Member l'Alliance Scientifique Universalle de France, etc. Boston: Richard G. Badger, publisher.

We can not state the reasons Dr. Shufeldt gives for writing this work better than given in his introduction to the work: "When one comes to write a book upon such a subject as is treated of in the pages of the present volume, there is usually some very definite reason that inspires the undertaking. This was distinctly the case in the present instance, and apart from all other considerations, be their nature what they may, my object in publishing a book on the negro race as it is now represented in this country, has been for the sole purpose of pointing out, from a purely scientific viewpoint, the effect that these introduced Ethiopians have had upon our progress and civilization in the past and what their continued presence among us means in the future." The fact is that the unmixed African in this country is just as much a negro today as his ancestors were before him in Africa, but the great danger that is assailing American civilization is the intermingling of the blood of a pure white race that must govern the nations of the world, and be superior to all others.

PHYSICAL DIAGNOSIS, With Case Examples of the Inductive Method. By Howard S. Anders, A. M., M. D., Professor of Physical Diagnosis, Medico-Chirurgical College, Philadelphia; Physician to the Philadelphia General Hospital, Tuberculosis Department; Late President to the Pennsylvania Society for the Prevention of Tuberculosis; Member American Medical Association, American Climatological Association, American Association for the Advancement of Science, etc. With eighty-eight illustrations in the text, and thirty-two plates. New York and London: D. Appleton & Co.

It is pleasing to note the fact that the author takes exceptions to the methods generally employed of scrutinizing the chemical and microscopical aspects of a patient's secretions and excretions in deference to the physical signs and objective symptoms. This is a move in the right

direction, and will give this work the prestige that should be accorded to one who dares to give his personal opinion, although it may seem to jar a little on obscure methods. We want diagnosis of troubles from the standpoint of efficient data and efficient correlation; then we can be of service to our patients. This work more fully covers the point of physical diagnosis in a practical way than those who have hobbies to ride, and can only see through such glasses. We commend this work to our friends, as we believe it will take a place as the standard authority upon the subject.

CLINICAL PSYCHIATRY. A Text-Book for Students and Physicians. Abstracted and Adapted from the Seventh German Edition of Kraepelin's "Lehrbuch der Psychiatrie." By A. Ross Diefendorf, M. D., Lecturer on Psychiatry in Yale University, Member of the American Neurological Association, of the New York Neurological Association, of the New York Psychiatrical Society, and of the American Medico-Psycological Association, etc. New edition, revised and augmented. New York: The Macmillan Company. Price, $3.75.

The sole object of this work is to educate the American physician along the line of thought according to Kraepelin's views, a full translation of which would have been too large, and would not serve the function for which it was intended, to interest the American reader; therefore, the writer has taken the liberty of abbreviating such matters that would not be interesting to his American brethren, although every thought that would lead to its value on the subject, and elucidate it for intelligent reading, has been retained. It is a work worthy the deepest thought. The student in psychiatry will appreciate this work, and find much food for thought.

POST-OPERATIVE TREATMENT. An Epitome of the General Management of Post-Operative Care and Treatment of Surgical Cases, as Practiced by Prominent American and European Surgeons. Together with Suggestions Concerning the Technic of Certain Operations with a View to Securing Better Post-Operative Results. By Nathan Clark Morse, A. B., M. D., Surgeon-in-Chief to "Emergency Hospital," Eldora, Iowa; District Surgeon, Chicago & Northwestern and Iowa Central Railways; ex-President Iowa State Association of Railroad Surgeons; Member American Medical Association, Pan-American Medical Congress, International Association of Railroad Surgeons, etc. Second edition. Revised and enlarged. Containing five plates and one hundred and seventy-five other illustrations. Philadelphia: P. Blakiston's Son & Co. Price, $4.00.

The family physician calls on the surgeon to perform an operation, and the operation is successfully done—the surgeon is relieved. Here comes in the post-operative treatment, and the case is either one in which the operation was successful, but the patient died, or the post-operative treatment was done successfully and the patient was cured or relieved. It would seem a crime to allow a patient to collapse after a successful operation, unless the patient was in a bad condition, and the operation was a last resort. The operation being done, with a chance in the patient's favor, the author believes that the post-operative treatment should have the most careful attention, as under the most favorable care untoward conditions occur at times. This is the only work of this kind that we have been called on to review, and believe it to be exclusive. Add this work to your library, and you will often refer to it.

THE HOME LIFE IN ORDER, OR PERSONAL AND DOMESTIC HYGIENE. By Alfred T. Schofield, M. D., late Lecturer and Examiner, National Health Society and Member Sanitary Institute; Vice-President and Examiner British College Physical Education; Hon. Physician Friedenheim Hospital, etc. New York: Funk & Wagnalls Company. Price, $1.50.

This book has many good traits, and should be placed in the homes by the family physician, because it will often be a great aid, especially when accidents happen and prompt action, of the right kind, will often delay serious results until the physician can arrive and give the proper attention. It gives pointers on hygiene of the household, and tells all that should be known and done in the absence of the physician. Dr. Schofield is well versed along this line of thought, and tells his ideas in a pleasing way, devoid of much technical matter that could only confuse the lay reader. Copies of this book should be placed in the homes of a doctor's best patrons.

MORRIS'S HUMAN ANATOMY. A Complete Systematic Treatise, by English and American Authors. Edited by Henry Morris, M. A. and M. B., London; F. R. C. S., England; President of the Royal College of Surgeons of England; Consulting Surgeon to Middlesex Hospital, London; Honorary Member of the Medical Society of the County of New York; formerly Chairman of the Court of Examiners of the Royal College of Surgeons; Examiner in Anatomy in the University of Durham, and Examiner in Surgery in the University of London; and J. Playfair McMurrich, A. M., Ph. D., Professor of Anatomy, University of Michigan; Member Association of American Anatomists; Member of Advisory Board, Wistar Institute of Anatomy, etc. Ten hundred and twenty-five illustrations, three hundred and nineteen printed in colors. Fourth edition, revised and enlarged. *In Five Parts.* Part I.—General Morphogeny, Osteology, Articulations. Price, $1.50. Part II.—The Musculature, the Organs of Circulation, the Lymphatics. Price, $2.00. Philadelphia: P. Blakiston's Son & Co.

This work has the advantage of other works on anatomy, owing to the fact that it can be had in one volume or five separate ones, giving the subjects a division that should find appreciation by a busy physician. The volumes have the subjects carefully noted on back of cover, and, therefore, easily and quickly scanned for the information wanted. We would suggest that general practitioners get this anatomy in parts, and thus have ready reference. To comment on Morris's Anatomy would be useless, as it has stood the test to its fourth enlarged and thoroughly revised edition. Get it now, while it is new.

THE ABDOMINAL AND PELVIC BRAIN. With Automatic Visceral Ganglia. By Byron Robinson, B. S., M. D., Chicago, Ill., Author of "Practical Intestinal Surgery," "Landmarks in Gynecology," "Life-size Chart of the Sympathetic Nerve," "The Peritoneum, Its Histology and Physiology," "Colpoperineorraphy and the Structures Involved," "The Mesogastrium," "Splanchnoptosia," Professor of Gynecology and Abdominal Surgery in the Illinois Medical College; Consulting Surgeon to the Mary Thompson Hospital for Women and Children, and the Woman's Hospital of Chicago. Hammond, Ind.: Frank S. Betz, publisher. Price, $5.00.

We can not name a reader of THE MEDICAL BRIEF who has not profited from his contributions to its pages. For years he has given text and illustrations on our pages which is proof of his advanced ideas of an original character, which have given new thoughts to our readers, especially along the lines of the abdominal sympathetic nervous system. A great amount of practical ideas gleaned from his autopsies and in his bedside experience, places him as a peer in his profession. This work is his original thought, and he has brought it up to an exact refutation of his claim. It is thoroughly illustrated. Do not fail to read it.

A MANUAL OF OBSTETRICS. By A. F. A. King, A. M., M. D., LL. D., Professor of Obstetrics and Diseases of Women in the Medical Department of the George Washington University, Washington, D. C., and in the Medical Department of the University of Vermont, etc. Tenth edition. Revised and enlarged. With three hundred and one illustrations in the text, and three plates. Philadelphia and New York: Lea Brothers & Co. Price, $2.75.

The progressive physician and the energetic student would not consider his library complete without a copy of Professor King's work on obstetrics. It is an up-to-date teacher, and a valuable aid to the student and practitioner, who has no time to pore over larger works to only find more verbiage than his limited time allows him to read in an emergency; he finds it here more condensed and readily accessible and reliable, which is the main point. The demand for a tenth edition shows the full appreciation in which it is held.

CLINICAL TREATISES ON THE SYMPTOMATOLOGY AND DIAGNOSIS OF DISORDERS OF RESPIRATION AND CIRCULATION. By Professor Edmund von Neusser, M. D., Professor of the Second Medical Clinic, Vienna; Associate Editor Nothnagel's Practice of Medicine. Authorized English translation. By Andrew MacFarlane, M. D., Professor of Medical Jurisprudence and Physical Diagnosis, Albany Medical College; Attending Physician to St. Peter's and Child's Hospital and Albany Hospital for Incurables. New York: E. B. Treat & Co. Price, $1.50.

This work treats of dyspnea and cyanosis, and dwells on the all-absorbing topic of searching for the specific cause of a disease, pushing into the background the manifest clinical evidences of the disease, and regarding them of subordinate

value and, apparently, even of negligible worth. The diagnosis of disease must, in the great majority of cases, be determined at the bedside, and not in the laboratory. Laboratory findings are most valuable aids to diagnosis, but are not, except in a few instances, diagnoses themselves, and never substitutes for clinical bedside work. Professor Edmund Neusser, with his rare diagnostic instinct, and his almost uncanny memory of clinical facts, and their co-relation to pathological findings, typifies, in the strict sense, the modern master clinician.

THE PRACTICAL MEDICINE SERIES. Comprising ten volumes on the year's progress in medicine and surgery. Under the general editorial charge of Gustavus P. Head, M. D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Vol. I.—General Surgery, edited by John B. Murphy, A. M., M. D., LL. D., Professor of Surgery in Rush Medical College (in affiliation with the University of Chicago). Series, 1907, Vol. II. Price, $2.00. Vol. III. —The Eye, Ear, Nose and Throat. Edited by Casey A. Wood, C. M., M. D., D. C. L., Albert H. Andrews, M. D., Gustavus P. Head, M. D. Price, $1.50.

In this series of works, published in monthly intervals, we find the entire field of medicine and surgery fully covered. While they are, primarily, for the general practitioner, and can be had for $10.00 for the series, any volume can be purchased separately, if desired.

A TEXT-BOOK OF PRACTICAL THERAPEUTICS. With Especial Reference to the Application of Remedial Measures to Disease, and Their Employment Upon a Rational Basis. By Hobart Amory Hare, M. D., B. Sc., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital; one time Clinical Professor of Diseases of Children in the University of Pennsylvania; Laureate of the Royal Academy of Medicine in Belgium, of the Medical Society of London; Member of the Committee of Revision of the United States Pharmacopœia of 1905. Twelfth edition, enlarged, thoroughly revised and largely rewritten. Illustrated with one hundred and fourteen engravings and four colored plates. Philadelphia and New York: Lea Brothers & Co. Price, cloth, $4.00; leather, $5.00; half morocco, $5.50.

This work has been before the medical profession for seventeen years, and now comes to us in its twelfth revised edition. What greater monument to its intrinsic worth? Some of the editions have been reprinted several times. It is a standard without a peer. A companion work to this one is Schleif's Materia Medica and Therapeutics, which will serve to carry the student up to a full understanding of Hare's Text-Book. The price of Schleif's work is $2.50, and we will notice under another heading. In purchasing medical books it is always well to get the best.

SCHLEIF'S MATERIA MEDICA AND THERAPEUTICS. A Pocket Text-Book of Materia Medica, Therapeutics, Prescription Writing, Medical Latin and Medical Pharmacy. By William Schleif, Ph. G., M. D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, New York; Visiting Surgeon, Bellevue Hospital, New York. Third edition, revised and enlarged. Philadelphia and New York: Lea Brothers & Co. Price, $2.50.

This is a manual for students and practitioners, and in conjunction with Hare's Text-Book covers all the points in therapeutics and materia medica that is desirable by any student or practitioner. In addition to the parts on physical properties, physiological action, therapeutics and toxicology of each medicinal agent, chapters wil be found on prescription writing, medical Latin, medical pharmacy, and practical anesthesia, tables of doses, of poisons and antidotes, and of incompatibilities. This work is thoroughly up-to-date in every respect, and will prove a valuable addition to a physician's library. This work is one of a series bound in uniform style, in a handsome cover that is at once attractive and lasting. Secure one of these works and you will want the others.

URIC ACID. An Epitome of the Subject. By Alexander Haig, M. A., M. D., Oxon., F. R. C. P., Physician to the Metropolitan Hospital, and the Royal Hospital for Children and Women; Author of "Uric Acid as a Factor in the Causation of Disease," and of "Diet and Food in Relation to Strength and Power of Endurance, Training and Athletics." Second edition. Philadelphia: P. Blakiston's Son & Co. Price, $1.00.

The subject of uric acid, as a factor in disease, would lead an author into unfathomable depths, if he did not read after an authority who had made the subject his life calling and argument.
